Dr. Hubert Schoonmaker of Clifton Springs, referring to the effect of the internal secretions upon the circulation, said they had come to recognize in these later days such a thing as the "thyroid heart," and the general practitioner was the first man who ought to recognize the "thyroid heart." To make a diagnosis of cardiac neurosis, neurasthenic heart, or gastrointestinal reflex, or what not, did not mean much. If they could have recognized at the outset the cardiac condition or the thyroid condition, they could have taken care of the patient in such a way that, in all probability, Graves' disease would not have developed. Every internist should recognize in the face of cardiac arrhythmia, and particularly in cardiac palpitation, which was at all persistent, the probability of disturbance of the heart due to abnormal internal secretions and possibly hyperthyroidism.

Dr. Benjamin W. Stearns of Unadilla recalled a patient recovering from typhoid fever who was taken with a severe sciatic pain in the hip. After one hour the pain moved to the region of the heart and death occurred in twenty minutes. Dr. Bishop's paper recalled his own personal case of a strained heart which did not improve under the usual heart tonics, but he entirely recovered after the use of tincture of strophanthus in ten-drop doses, four times a day, this being continued for a full year. He said he had used strophanthus as a heart tonic exclusively for the past six years and he considered this drug the most effective and reliable heart tonic.

Dr. Neuhof of New York said he could not agree with Dr. Lambert that pain in most of these cases was due to changes in the myocardium. He had seen similar conditions in children with acutely dilated hearts, where the main lesion was endocardial. He had made a study of twenty odd cases of arterial fibrillation and the first symptom was dyspnea.

Dr. Henry S. Stark of New York said that in the absence of any diagnostic instrument of precision the clinical diagnosis of uncomplicated myocarditis must necessarily be a tentative one. The truth of this statement was disclosed by the frequency with which a clinical diagnosis was made of a myocarditis, but which diagnosis was controverted by the post-mortem findings. Many cases of clinical myocarditis were masked cases of endocarditis of a low grade, not advanced enough to produce adventitious heart sounds or a hypertrophy.

Dr. Anthony Bassler of New York said that he was sorry not to have heard more regarding the etiology of cardiac disease, for he was sure that they must go further than a consideration of rheumatism, syphilis, chorea, and certain local and general infections to account for these cases. There was no doubt in his mind that many were due to intestinal disturbances, for analysis of the intestinal contents gave findings in so many instances of choline and other substances which showed a protein breakdown. It was shown that toxic substances were constantly going into the circulation. The mucous membrane of the intestine did not deintoxicate and it could not take care of what was brought to it. If these cases were looked upon in this way and if they were properly dieted, if more oxygen was brought to the tissues by keeping the patients in the open air, having them take exercise, etc., and afterwards adding such extracts that might be helpful, it would be better for them.

**Association of Uterine Growths with Goiter, Typical and Atypical Exophthalmic Goiter.**—Dr. Henry L. Elsner of Syracuse read this paper. The object of this paper was to call the attention of the profession to the very large proportion of uterine growths associated with goiter, typical, and atypical, and to impress further the frequency of the atypical cases and to encourage the thorough examination of all the organs of the body in the presence of goiter, large or small; if this was done, the number of associated anomalies would prove surprising. Exophthalmic goiter developing during pregnancy was exceedingly rare; it had only occasionally happened that the complex was influenced by parturition. It might be concluded that these patients were unfavorably in-

fluenced by pregnancy and that convalescence had been abnormally slow. In his series of cases patients with exophthalmic goiter, with or without uterine growths, had rarely conceived. During pregnancy all symptoms were liable to be aggravated, particularly those referable to the nervous system. So far as the influence of castration on the thyroid gland was concerned, it was impossible to conclude that exophthalmic goiter was either favorably or unfavorably influenced by such treatment. Dr. Elsner had made an analysis of 5,370 cases of internal diseases and 186 cases of goiter were included. Of this number 89 were simple uncomplicated goiter, 1.66 per cent.; 97 were diagnosticated as belonging to the class of exophthalmic goiter, 1.8 per cent.; of this number 55 proved to be atypical exophthalmic goiter, 1.2 per cent.; 42 were typical in all symptoms of exophthalmic goiter, 78 per cent. Fifteen per cent. of all the cases of goiter seen (186), included in 5,370 cases of internal disease, proved to be associated with uterine myoma or fibromyoma. Since 1881 his clinical experiences had demonstrated the frequent association of thyroid perversion, often hyperthyroidea, including simple goiter and exophthalmic goiter, typical and atypical with uterine growths, fibroid, and myomatous. He felt that he was justified in teaching since 1881 the unusual frequency of uterine growths with thyroid abnormalities, more particularly with the various forms of goiter, typical and atypical exophthalmic goiter. There were to be considered two facts: One, surprisingly prominent, proved that the disease was often self-limited and spontaneous recovery was not at all uncommon; second, the subjective and objective manifestations proved the protean character of many goiters.

Dr. John A. Witherspoon of Nashville, Tenn., said that for many years he had noted the relation of uterine troubles and Basedow's disease but what this relationship bore he did not know because so little was as yet known regarding the internal secretions. Shock, anxiety, worry, etc., certainly exaggerated the growth of the gland. Hypothyroidism was without doubt often caused by the excitement attendant upon merely preparation for some operation.

Dr. A. Jacobi of New York said that he had seen but a few cases which confirmed Dr. Elsner's conclusions and his vast knowledge of the literature on the subject.

**Benzol in the Treatment of Leukemia, with Results in a Case of Myeloid Form.**—Drs. Jerome Meyers and Thomas W. Jenkins of Albany presented this paper. From a study of the case they reported and the cases that had been reported, they drew the following conclusions: Benzol was a valuable addition to the therapy of leukemia of any kind. Its institution was, however, so recent, and clinical experience still so scanty, that definite conclusions as to its intrinsic value should be held in abeyance. It would seem to have no uniform action: in all cases it reduced the number of the white cells but in some, apparently those with very high counts, it did not reduce the leucocytes to normal; while in cases of 100,000 to 200,000, it might give brilliant results with normal white count greatly diminished or normal spleen, distinct pain in weight and strength, and loss of fever. On the other hand, they might have paradoxical reactions with failing white counts and gain of strength with no change in the spleen, or they might find a decrease in the spleen with persistent high leucocytic counts, or there might be low counts with many pathological leucocytes, or there might occur sudden leaps in the number of white cells. The red cells and the hemoglobin were usually very beneficially influenced. When *x*-rays could be used in combination, very favorable results might be obtained, the blood returning to normal with no persisting myelocytes. It was very probable that the results of benzol-therapy were variable for two reasons: (1) The cases in themselves varied in intensity and in the fundamental pathological conditions or etiological factors in the bone marrow, the spleen, or lymphoid system; (2) the results were in some way dependent on the size of the dose of benzol, which dose might be either stimulating or depressing to the tissues involved, and this dose might be peculiar in a marked degree to each case or individual. They would, therefore, suggest that the effect of benzol should be carefully checked by daily blood examinations so as to gauge the optimum dose, and to forestall any symptoms of benzol poisoning.

---

SECTION ON PEDIATRICS.

*Tuesday, April 29—First Day.*

Dr. Henry L. Shaw of Albany, in the Chair.

**The Wassermann Reaction in Various Conditions in Children.**—Dr. L. Emmett Holt of New York premann reaction not only enabled one to be certain of the existence of syphilis in many doubtful conditions but also excluded syphilis in many cases where it was formerly suspected. It was the consensus of opinion that latent as well as active syphilis gave a positive response to this reaction. It was also the general belief that children who reacted positively should receive the benefit of antisyphilitic treatment. Like all laboratory tests the Wassermann reaction was not infallible. Positive reactions might be met with in certain cases of scarlet fever and in infection with the trypanosomes; neither of these conditions would be likely to be confused with syphilis. Errors in faulty technique must be taken into account. It was absolutely essential that the reagents used should be right. The antigen must be good and well tested; the sheep or human corpuscles must be fresh and properly washed. Errors occurred most frequently on the positive side so that children tested for syphilis were pronounced syphilitic when they were not. A series of observations had been carried on in the Babies' Hospital in order to answer the question as to the frequency of syphilis in the ordinary run of hospital infants as well as in some special conditions. The Noguchi modification of the Wassermann reaction was used in all of their cases. This method had the advantage in infants of requiring much less blood than the Wassermann test. All of the tests had been made at the Rockefeller Institute under the supervision of Dr. Noguchi. They, therefore, felt sure of the technique and the accuracy of their observations. During the period of their observations 34 cases of hereditary syphilis had been admitted for treatment. In 31 of these, blood tests were made, and 30 gave a positive reaction. The infant not responding had undergone inunctions of mercury for a period of three months. Previous treatment with mercury did not seem to affect the reaction unless it had been continued for a considerable time and with regularity. Of the 30 patients giving positive reactions, nine had been treated with mercury. The positive reaction in these cases, some of which had been treated from birth, showed how incomplete and uncertain was the cure of syphilis effected by mercury and potassium iodide. Of 178 tests made in hospital patients showing no definite signs of syphilis, positive reactions were obtained in but eleven and five of these were shown upon fuller investigation or subsequent findings to be pretty clearly syphilitic. Two of the remaining four were doubtfully so. The great proportion of congenital deformities had no relation to syphilis since not a single positive reaction was obtained in 56 consecutive cases. Of 62 patients suffering from malnutrition only five gave a positive reaction and were included in the group mentioned above. Of the remaining 57, nearly one-third had very considerable enlargement of the liver or spleen or both. Since these cases examined were selected from a much larger number as those most likely to be syphilitic, they could not regard syphilis as a common cause of marasmus in the patients admitted to the Babies' Hospital. Since the error was almost invariably on the positive side, the technique of those who found a large percentage of positive reactions among marasmus patients in institutions was open to suspicion. It was evident that mere swelling of the liver and spleen even when associated was not to be regarded as a very important sign suggestive of syphilis in infants suffering from malnutrition. Both were much more likely to be seen with rickets than with syphilis. Mere swelling of the superficial lymph nodes, whether occurring alone or with swelling of the liver and spleen, had no special significance. The only glandular swellings that did suggest syphilis were those of the epitroclears when this occurred without any peripheral lesion to explain it.

Dr. L. E. LaFétra related his experience with the Wassermann reaction at Bellevue Hospital. They employed only the original method of Wassermann. All suspected cases were submitted to examination and all cases in which there was an underlying luetic condition. They had submitted 82 cases to examination two or more times. They found syphilis present in 44 cases in which it was suspected and in 15 cases where they had thought it was not present. The spleen was enlarged in three-fourths of their cases that gave a positive reaction. In young infants a large spleen need not lead one to suspect syphilis. In fifteen cases not supposed to have syphilis the family history was positive in two cases and negative in nine. One should not put too much reliance on a negative family history. As an assistance to diagnosis the Wassermann test was of great service, especially in skin eruptions and stomatitis. The Wassermann reaction should be used in all doubtful cases. Observations should be made as to the results of treatment with the mercurials and neosalvarsan in children.

Dr. Thibaudeau of Buffalo said that in his tests the original method of Wassermann had been carried out. His experience led him to conclude that when the Wassermann reaction was positive this might be considered good evidence that syphilis was present. When the reaction was negative the conclusion was not so positive that syphilis was absent. He had examined several syphilitic fetuses or infants dying very shortly after birth in which the reaction was negative. He explained this by the fact that the infection was overwhelming and hence the formation of antibodies had not taken place. When they obtained doubtful reactions or what they called a positive-negative reaction in nervous conditions they were coming more and more to acknowledge them as positive. He cited an instance of a child, born of a mother who had an active lesion, which appeared to be perfectly healthy but who was now developing a gumma.

Dr. John E. Welch of New York called attention to the possible sources of error in the technique of these tests. In the original Wassermann method one source of error was the complement content of guinea pig serum. Frequent bleeding of the same pig led to a decrease in the complement content of the serum. In jaundiced cases a weak Wassermann reaction was sometimes obtained. Many positive Wassermann reactions were obtained in children suffering with malnutrition and with bile salts in the blood. These sources of error should be kept in mind.

**Clinical Reports of Ten Cases of Pulmonary Tuberculosis in Children Treated with Mixed Bacterins.**—Dr. Louis C. Ager of Brooklyn presented this paper. He said that although recent investigators had shown that the tubercle bacillus alone might produce destructive tissue changes in the lungs it was generally believed that such changes were the result of secondary invasion of various pyogenic organisms. If this were true and if the pathological process was entirely local the use of bacterial vaccines was indicated theoretically at least. The reason advanced for introducing into the circulation the toxins of a disease from which the patient was already suffering was that the reaction to the toxin was largely local and that the active acquired immunity was also largely local. If, therefore, a general systemic reaction could be produced they might expect a systemic immunity. In spite of recent reports of Pettit and Brown, the writer said he was convinced by the investigations of Avery that the secondary organisms were practically never found in the blood of phthisical patients, even in the terminal stages. If that were true pulmonary tuberculosis was almost entirely a local process and the mixed vaccines ought to be of benefit. With these facts in view he chose ten patients all showing active lesions and representing different types and stages of the disease. He administered Mulford's Mixed Influenza Bacterin containing the bacilli of influenza, of Friedlander, of the pneumococcus, streptococcus, and staphylococcus, as well as diphtheroids and the *Micrococcus catarrhalis*. This product was used because it contained the organisms occasionally found in washed specimens of sputum. After relating the histories of these cases he concluded that no definite reactions were observed in any case. A careful study of the four hour rectal temperatures showed no special changes in any case. In four cases there were slight changes that might have been attributed to the treatment. The only positive deduction that could be drawn from these observations was that this particular bacterin bore no special relation to these particular cases. It was quite possible that autogenous vaccines might have shown a definite reaction.

Dr. Edward G. Whipple of Rochester said that he regretted that Dr. Ager had not met with better success. When tuberculosis was sufficiently far advanced to be recognized there was present a mixed infection, but until they could calculate the amount of infection and the amount of bacterins they could not expect to get definite results. Tuberculosis was only truly incipient in childhood and it was important that the pediatrician should unite in the campaign for clean milk and sanitary surroundings for children. It was only by keeping the resistance of the child up to the proper level that they could hope to combat tuberculosis in childhood. It did not seem to him that the giving of mixed bacterins was scientific medicine or good therapeutics. Again, until they found a specific treatment that could be put in the hands of the general practitioner they must continue to use general treatment. The plan they had used in the Tuberculosis Hospital of Rochester was the treatment of the tuberculous patient in the institution and preventive measures. The treatment of tuberculosis in children did not differ from that in adults. In their institution the child received a school education in an open air school. Some were under home treatment, but this had proved unsatisfactory. They sent children from homes where a parent was afflicted with the disease to a preventorium where they did their school work in the open air, took proper rest, and graduated exercises. After they left the school a follow-up system was used. Relapses were often due to home conditions. They removed adenoids and enlarged tonsils, treated diseased ears, and corrected orthopedic defects. The anemic, poorly nourished child nearly always had tuberculosis. He, therefore, made a plea for the segregation of adults, the medical examination, not inspection, of school children; the care of the tuberculous child for one year, and insisted that these measures should be applicable to the rich and the poor alike.

Dr. H. J. Brayton of Rochester said he had had no experience with the bacterins, but thought they might be useful in cases of the chronic type. Cases doing well on the routine treatment should be let alone. Improvement was especially noticeable among the children in the open air schools. If the children could be under observation longer better results would be obtained. In their sanatorium they isolated the advanced cases and kept the incipient cases by themselves. They got most of their cases in the incipient stage. The cases should be kept under observation for one year. Dr. Matthias Nicoll of New York said that he felt gratified that Dr. Whipple had spoken against this so-called specific therapy, but he had not spoken strongly enough. Such a shotgun mixture of bacteria was absolutely absurd.

Dr. L. Emmett Holt emphasized what Dr. Nicoll had said. He did not agree with the writer of the paper that such results should be published. Such therapy did harm by tempting the unwary to pin faith on a specific to the neglect of routine measures of treatment. Furthermore, it was not wise to employ such a commercial product and the recommendation of such a product of any firm was out of place in such a meeting.

**Rational Treatment of Hemorrhagic Affections in Children.**—In the absence of Dr. Le Grand Kerr of Brooklyn this paper was read by title.

Dr. John E. Welch of New York, in discussing the subject of hemorrhagic affections in children, said that the manner in which the bleeding began was familiar to all. Any persistent bleeding in an anemic child called for definite and well-directed treatment. Different methods had been employed, as the injection of normal human blood serum, or the serum from animals, as the horse, the sheep, etc. It was well known that serums from a different species caused a reaction. This was illustrated by the fact that diphtheria antitoxin produced a slight reaction in 80 per cent. of the cases injected. The effort to overcome a serum sickness was an additional strain on the system of a child already depleted by loss of blood. With regard to the etiology of hemorrhagic disease, he stated that he did not believe that it was a blood disease, but rather a disease of the general tissues produced in many ways and causing a change in the endothelium of the blood vessels. The increased blood pressure, the altered state of the blood, and the change in the endothelium were secondary to some general disease which might be the result of mineral poison or of syphilis. After a long period of tissue starvation bleeding began. After reviewing the theories of coagulation advanced by Dr. Howell of Johns Hopkins as evidence that the hemorrhage was not due to conditions in the blood itself, Dr. Welch advocated the use of normal human blood serum because it had no untoward effects, was easily obtained, and very effective. In anaphylaxis there was a reduction in the complement of the blood and a decrease in blood pressure and the addition of the serum from an animal further reduced the complement and hence was a mistake. He believed that normal human blood serum served to control hemorrhage chiefly through its value as a food. In a series of premature infants upon which he had made observations those who were given normal human blood serum survived. They were now working on the problem of serum precipitation by acetone and ether in the hope of obtaining a product easily soluble in water and which would control hemorrhage, and successful work in this line had been reported.

Dr. L. E. LaFétra said he thought it would be of interest to some of them to know of the work that Dr. Schloss had done in the use of blood from a member of the family or a near relative. He had used the whole blood in fifteen or twenty cases. It was surprising how readily the whole blood was absorbed without clotting when injected into the back. It was entirely absorbed in two days. Dr. LaFétra cited the case of a boy, seven years of age, who was suffering from severe purpura. He was given an injection of serum, then a transfusion,

after which he improved for three weeks. He then relapsed and thirty c.c. of whole blood was injected four times during a period of two months, since which time the boy had remained well. In two cases of hemorrhage in new-born infants 20 c.c. of whole blood was used the first injection, and 30 c.c. for the second, after which there was complete cessation of the bleeding. The great advantages offered by the whole blood were that it took less time to procure it and that it did not take as large a quantity of blood as when the serum alone was used. There was no reaction following the administration of human blood. A combination of the method of Dr. Welch and that of Dr. Schloss could be used, giving the first injection of whole blood and following that by an injection of serum.

**Diphtheria.**—Dr. Joseph R. Culkin of Rochester read this paper. He stated that all agreed that the bacteriological examination was the only sure way to diagnose diphtheria, but when one got a negative report, or even two or three of them in a case of manifest diphtheria, it was important for the clinician to rely upon his own diagnosis and to use antitoxin freely until the case was cleared up, when he might get a late positive culture. A negative culture might lead a family prejudiced against antitoxin to forbid its further use, and so valuable time might be lost in waiting for more cultures. When the writer met this frame of mind he made it a practice to use a large initial dose in the first instance. He had had negative cultures reported in cases that afterward developed paralysis characteristic of diphtheria and in laryngeal cases with no membrane in the pharynx. He would forbid the use of antiseptic until after the culture was taken. There was nothing to be said against the culture method but the necessity of relying upon the clinical diagnosis and treating the case energetically while waiting for a return from the culture should be emphasized. The nasal cases were a potent factor in keeping up the spread of the infection and should be sought for with great care, especially in institutions. Immunity was powerless against those cases as the immunity ran out. Conditions which produced epthelial necrosis and much membrane which resembled diphtheria should teach the clinician to rely upon well-made cultures for his final diagnosis, but he should use antitoxin until the diagnosis was established. Dr. Culkin advocated plenty of antitoxin given as early as possible. In marked pharyngeal and tonsillar cases at least 10,000 units should be used; in nasopharyngeal cases 15,000 units, and in laryngeal cases 20,000 units, to be repeated in twelve hours if results were not apparent. It was well to examine the lungs which might be invaded as the throat was clearing; a fatal termination could only be avoided in bronchopneumonia by large doses of antitoxin. Immunizing doses of antitoxin might be given to the same individual a number of times without causing any untoward symptoms. The prejudice against antitoxin did not seem to abate and all sorts of conditions were charged to it, but the use of a sufficient dose early would do much to diminish this feeling. In cases seen in an almost moribund condition, it was futile to use antitoxin unless one was prepared to use enormous doses at once, as less than these large doses only tended to have antitoxin charged with the deaths sure to follow.

Dr. Matthias Nicoll, Jr., of New York said he congratulated Dr. Culkin on his firm attitude in regard to the importance of antitoxin at the earliest possible moment that diphtheria was suspected. No real harm to the patient would follow a dose of antitoxin in any event and frequently a grave danger might be averted. In severe cases the clinical findings should be the guide of the physician and on no account should a delay of eighteen hours be tolerated while waiting for culture returns. As regarded the inconsistencies of the culture reports, they were sometimes not properly taken. Purely laryngeal cases, especially at first, frequently gave negative results if the swab was taken in the usual way. If, however, the swab was slightly bent and a culture made directly from the interior of the larynx this error would be largely avoided. Young children convalescing from scarlet fever who had a profuse purulent nasal discharge, especially in a hospital, should have a large dose of antitoxin immediately. The importance of making direct smears in addition to a culture was not generally recognized: this was especially applicable to the obscure, ulceromembranous cases referred to by Dr. Culkin. In regard to immunization they gave 1,000 units of antitoxin to every case of scarlet fever on admission to Willard Parker Hospital; if the patient was exposed to diphtheria the dose was repeated at weekly or longer intervals. The same procedure was carried on in measles epidemics. The amount of antitoxin suggested by Dr. Culkin was somewhat larger than was given as a routine measure at the contagious disease hospitals in New York. He believed that more than 10,000 units in children was rarely necessary, since with this dose the blood was known to contain an amount of antitoxin which was more than a hundred fold sufficient to neutralize any conceivable amount of antitoxin which was capable of being neutralized. In regard to a second dose of antitoxin in twelve hours, Dr. Park had had charts prepared to demonstrate the time required for antitoxin to reach the blood stream and the amounts of antitoxin contained in the blood at different periods of time. It was found that the antitoxin reached the blood stream slowly but steadily, increasing up to the third, fourth, or fifth day after the injection and then slowly decreasing. Therefore, if a second dose was given twelve hours after the first the beneficial effects attributed to it really were due to the continued absorption of the first dose, the second only gradually contributing its share. A second chart showed the results in four cases of diphtheria which received 10,000 units of antitoxin intravenously. It showed very plainly that in this method a very large amount of antitoxin went into the blood stream at once and immediately decreased, yet there was a sufficient quantity in the blood for a week or more. If one felt that the initial dose was not sufficient a second dose might be given but it should be given intravenously. Antitoxin should be given intravenously in cases which were in desperate straits. With regard to the beneficial effects of antitoxin in complicating bronchopneumonia Dr. Nicoll said he could not conceive of antitoxin influencing disease invariably caused by an organism other than that for which it was a specific. Dr. Nicoll said he was not prepared to state that intravenous injection was perfectly safe, but in their wide experience they had never had an accident.

Dr. Jerome S. Leopold of New York said he, too, wished to congratulate Dr. Culkin and to emphasize what he had said in regard to early and large doses of antitoxin. If a child was exposed at the end of ten days after an immunizing dose of antitoxin a second immunizing dose should be given. There was a difference of opinion as to the size of the dose in different localities. In Boston they used very large doses. As to the quarantine of diphtheria cases, interesting observations had been made in Germany where it was found that the sediment of centrifugalized urine contained diphtheria bacilli in practically every case, even after three months. The question arose as to whether all cases did not have bacilli in the blood and as to how long they might remain infective.

Dr. Thomas J. Walsh of Buffalo said he also wished to add his commendation to the stand taken by Dr. Culkin, especially in regard to the nasal cases and the measles cases which so often showed diphtheria on culture. Anaphylaxis was a very real thing and in those cases that were asthmatic von Pirquet had suggested the von Pirquet test and if a marked reaction took place anaphylaxis should be looked for. Another way was to give a small dose first and note the effect; then follow it by a large dose. In case anaphylaxis did occur atropine should be administered. The use of antitoxin intravenously was bound to come to the front. The preservative in the antitoxin if given intravenously might have a bad effect. The intravenous method was not an easy one. The intramuscular method was less painful than the subcutaneous and the intragluteal injection would be found convenient. Abroad they had a trick of performing extubation by suddenly tipping the child forward and often the tube, slightly loosened, would fly out. A point about tracheotomy was that of making a transverse incision between the rings of the trachea. This technique was easier than that in general use and gave satisfactory results. In the neuritis of diphtheria, the paralyses, heart lesions, etc., antitoxin was the best remedy they had thus far found. By introducing a spiral into the tracheotomy tube they could remove the membrane more easily. In diphtheria digitalis had been found useful in auricular fibrillation.

**Recurrent Vomiting in Children.**—Dr. A. Clifford Mercer of Syracuse read this paper. He stated that of the etiological theories of recurrent vomiting advanced that of acidosis as revealed by the presence of one or more acetone bodies in the urine had received most attention. With diminished power of oxidation the catabolism of carbohydrates became inadequate for the simultaneous combustion of fats. The catabolism of fat was therefore incomplete. Acidosis resulted and the acid products found their way into the urine as acetone, diacetic acid, or beta-oxybutric acid. Sedgewick found that creatinuria was associated with acetonuria, while the light colored stools passed before and during the attack indicated hepatic insufficiency. Acetonuria was found to be present however, in a large percentage of infants after

a change of diet. A temporary inability to digest carbohydrates seemed to cause carbohydrate starvation and this appeared to cause the acidosis. From a neurotic standpoint recurrent vomiting seemed to be related to migraine. The fact that the excretion of acetone by the lungs, kidneys, or skin sometimes did not occur during the prodromal stage but only after the onset of emesis and was present at and after the crisis supported the view that acidosis was an incidental effect rather than the fundamental cause of recurrent vomiting. In the first attack of recurrent vomiting diagnosis was liable to be difficult. In later attacks with a history of recurrence the diagnosis was easier. A gouty or neurotic family history, a high-strung, nervous child, recurrent attacks of violent, prostrating, wasting, uncontrollable, but self-limited vomiting without organic lesion, but with acidosis revealed by the odor of acetone in the breath, vomitus, or urine, following some marked offense to the nervous system rather than an obvious dietetic error, was a pretty definite and distinctive picture of the condition. In well-developed cases all methods of treatment had failed to stop the vomiting. The alkaline treatment had been remarkably successful in some hands and a failure in others. If the prodromata were recognized, the diet curtailed, the intestinal tract cleared and bicarbonate of soda given freely an approaching attack might be prevented. Successful abortive treatment suggested prophylactic treatment along the same lines. All factors that might be concerned in any way in causing recurrent vomiting should be eliminated and all available means of building up the resisting power of the child should be taken advantage of.

Dr. George E. Clark of Skaneateles said he wished to report a case of recurrent vomiting. The trouble began with indigestion when the infant was two months of age and was repeated at the age of five months when cow's milk was first given. Disturbances occurred at various periods during infancy. At the age of six years the attacks recurred at intervals of three months. The parents were very careful of this child's diet and he felt sure that the trouble was not due to error of that nature. The attacks in this instance seemed to be precipitated by nervous excitement. The only thing that gave any relief was menthol and this offered but slight help. Arseniate of strychnine was used to keep up the pulse. Experiments with dogs and cats had shown that excitement resulted in suspended digestion for the time being, and if this was the case why could not interference with the functions of any viscera be explained in the same way.

Dr. Charles L. Hincher of Rochester discussed the problem of the etiology of this affection and suggested that possibly the adrenals have something to do with the subject as they played an important part in sugar metabolism.

Dr. Thomas S. Southworth referred to the ease with which excitement gave rise to these acute attacks. The vomiting indicated the attempt of the system to eliminate some unfortunate product of metabolism. It would seem, then that active free catharsis was indicated. When free catharsis was established the vomiting stopped. The desired result might be obtained from calomel in some cases. Castor oil could not be given. The one laxative that seemed to fit the situation was citrate of magnesium. If the child could not tolerate large doses a tablespoonful could be given every twenty minutes or half hour. A certain amount might be vomited but a certain amount would pass through the pylorus. It had been his experience that the vomiting subsided within twenty-four hours in his cases, though it might be that the cases were of a mild type.

Dr. A. Clifford Mercer said he only wished to emphasize the necessity of eliminating early in the attack and of studying the prodromes and treating the patient before the attack.

Dr. DeWitt H. Sherman of Buffalo said he wished to emphasize what had been said about watching to prevent the attack, but he wished more particularly to emphasize what had been said about the neurosis. He cited three cases in which a cure was obtained by having the patients' eyes examined and fitted with properly adjusted glasses. The condition of the eyes might influence the metabolism in children.

Dr. Mercer said he could confirm what Dr. Sherman had said in regard to the importance of having the eyes examined in these cases.

**The Differential Diagnosis of the Paralyses Occurring in Early Life.**—Dr. Henry A. Gribben presented this paper. He stated that it was his purpose to formulate a working guide in the diagnosis of those conditions with which the pediatrician was most often confronted. He roughly divided the extremity paralyses into three groups: the pseudo palsies, the spastic, and the flaccid. Among the pseudo palsies, the most common conditions were immobilities due to pain. Injuries to bones, joints, and muscles would often simulate paralysis, polyarthritis, and osteomyelitis among the inflammations and scurvy and rickets among the diseases. The pain paralyses were positively differentiated by single points of tenderness, evidences of local injury, and the ability to move fingers and toes. It was important to consider the true and false palsies together. The false paralyses of rickets might be differentiated by the fact that motion was not absolutely lost and by the other stigmata of this disease. The second and spastic group was well illustrated by the cerebral palsies. Rigidity of the extremity involved, exaggeration of the deep reflexes, no reaction of degeneration, and no atrophy, were symptoms common to all types and were distinctly opposite to the symptoms of the flaccid type. General spasticity meant cerebral lesion or lesion of the lateral or posterior tracts of the cord. Flaccidity meant anterior cord disease or peripheral nerve lesion. The cerebral group might be hemiplegic, paraplegic, or diplegic, very rarely monoplegic. Sachs' classification according to the onset was a distinct aid in diagnosis. The prenatal forms due to defects and intrauterine injuries was best known as Little's disease and were paraplegic or diplegic with characteristic cross-legged progression. This term also applied to birth injuries. The acquired form might be due to hemorrhage, embolism, or thrombisis, and was more likely to be hemiplegic. There was also the acute form of meningoencephalitis which gave rise to the same symptoms.

The spinal type of spastic paraplegia was differentiated by the fact that it was distinctly hereditary, came on later than the eighth year, was slowly progressive, lacked the mental deficiency so common to birth palsies, and had no history of birth trauma. Other lesions giving rise to spasticity were cerebral tumor, abscess, and cyst. The spastic paralyses due to cord lesions might be grouped under injuries, inflammations, and diseases. Under injuries were included traumatic hemorrhage, fractures of the vertebræ, and compression due to spinal caries. Myelitis was the type of inflammation, tumor tubercle, and gumma of disease. Taking myelitis as the type they had the positive signs of sensory disturbance, sphincteric involvement, and involuntary spasmodic twitchings. These symptoms were pathognomonic of myelitis. Syphilis of the cord might have all the symptoms of myelitis, but with the difference that it involved the greater portion of the cord and the intensity of the symptoms was slight, as compared with the extensiveness of the area involved. There were certain rare conditions which should be tucked away in the subconscious mind, such as disseminated sclerosis, Friedreich ataxia, and hysteria. The third, or flaccid, group was made up of spinal and peripheral nerve lesions. Flaccidity, atrophy, diminution of reflexes and change in electrical reaction were the cardinal signs that distinguished this group. Anterior poliomyelitis must be differentiated from multiple neuritis as the peripheral type. In the subacute form of poliomyelitis the picture might be that of progressive muscular atrophy; until retrogression it might be impossible to distinguish the true condition. In Landry's paralysis, usually rare in children, the rapidly ascending palsy and involvement of the abdominal and thoracic muscles would be positive signs to differentiate it from both poliomyelitis and polyneuritis.

Dr. Wisner R. Townsend said that the paper was so complete that it needed no discussion. In order to bring out the difference between the flaccid and pseudo types he had watched the cases that came into the hospital for errors in diagnosis. The striking fact thus brought out was that many came with the wrong diagnosis because of lack of previous history. A careful history gave one a very different idea when he came to examine the case. He had seen rachitic cases in which there was complete loss of motion. He had ceased to attempt to use electricity because it was so terrifying to the children. He had produced two attacks of hysteria in this way and found the electricity of little use. He had learned more from the careful examination of individual muscles. Peripheral neuritis was rather rare in young children. Paraplegia had sometimes led them to suspect Pott's disease and this diagnosis had proved correct. In hysteria a lack of coordination or of a proper balance between the symptoms helped the physician to make a diagnosis. The ordinary tests, heat, pins, etc., he said, also had their value.

## Books Received.

*The* MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

VACCINE THERAPY. By R. W. ALLEN, M.D., B.S. Cloth; fourth edition; 444 pages; price $3.00 net. P. Blakiston's Son & Company, Philadelphia.

KLINIK FÜR PSYCHISCHE UND NERVÖSE KRANKHEITEN. By ROBERT SOMMER. 7 Band, 4 Heft; paper. Carl Marhold, Halle.

MEDICO-LEGAL EXAMINATIONS AND THE WORKMEN'S COMPENSATION ACT, 1906. By SIR JOHN COLLIE, M.D., J.P. 128 pages; cloth; price $2.00 net. Wm. Wood & Co.: New York City.

TRANSACTIONS OF THE AMERICAN CLIMATOLOGICAL ASSOCIATION, for the year 1912. Vol. 28. 342 pages; cloth. Printed for the Association, Philadelphia.

MECHANICAL VIBRATION. By M. L. H. ARNOLD SNOW, M.D. 476 pages; cloth; illustrated. Price $3.50. The Scientific Authors' Publishing Co., New York.

ALCOHOLISM. By FRANCIS HARE, M.D. Cloth; 269 pages; price $2.00 net. P. Blakiston's Son & Company, Philadelphia.

WHO'S WHO IN SCIENCE, International 1913. Edited by H. H. STEPHENSON. 572 pages; cloth. J. & A. Churchill, London.

THE CHILD. By "The Hope Farm Man." 192 pages; paper. The Rural Publishing Company, New York.

VERÖFFENTLICHUNGER der Robert Koch-Stiftung zur Bekämpfung der Tuberkulose; Herausgegeben vom Vorstand der Stiftung. Part III. Paper; 68 pages; illustrated. Von Kurt Bludorn, Georg Thieme, Leipzig.

VERÖFFENTLICHUNGEN der Robert Koch-Stiftung zur Bekämpfung der Tuberkulose; Herausgegeben vom Vorstand der Stiftung. Part IV. Paper; 54 pages; illustrated. By B. MOLLERS. Georg Thieme, Leipzig.

DIE LUETISCHEN ERKRANKUNGEN DER BAUCHORGANE. By HOFRAT DR. TH. HAUSMANN. Paper; 68 pages. Carl Marhold, Halle a S.

OCCASIONAL PAPERS ON THE PREVENTION OF SOME COMMON DISEASES IN CHILDHOOD. By J. SIM WALLACE, D.Sc., M.D., L.D.S. 103 pages; cloth; price 3 shillings sixpence net. Bailliere, Tindall & Cox, London.

THE BRADSHAW LECTURE ON THE BIOLOGY OF TUMOURS. By C. MANSELL MOULIN, M.A., M.D., F.R.C.S. 39 pages; cloth; price 2 shillings net. H. K. Lewis, London.

A DICTIONARY OF TREATMENT. By Sir WILLIAM WHITLA, M.A., M.D., LL.D. Fifth Edition; cloth; 1204 pages; price $16.00 net. Bailliere, Tindall & Cox, London.

STARVING AMERICA. By ALFRED W. MCCANN. Cloth; 270 pages. F. M. Barton, New York.

TRANSACTIONS OF THE AMERICAN GYNECOLOGICAL SOCIETY. Volume 37, for the Year 1912. Cloth; 502 pages; illustrated. Wm. J. Dornan, Printer, Philadelphia.

HANDBOOK OF DISEASES OF THE RECTUM. By LOUIS J. HIRSCHMAN, M.D. Illustrated; 2nd Edition; price $4.00 net; 339 pages; cloth. C. V. Mosby Company, St. Louis.

THE PRACTICE OF UROLOGY. By CHARLES H. CHETWOOD, M.D., LL.D. Illustrated; cloth; 816 pages. William Wood & Company, New York.

ORGANIC CHEMISTRY. By HOWARD D. HASKINS, A.B., M.D. Second Edition. 430 pages; cloth; price $2.00 net; illustrated. John Wiley & Sons, New York.

THE DEVELOPMENT OF THE HUMAN BODY. By J. PLAYFAIR MCMURRICH, A.M., Ph.D., LL.D. Fourth Edition; cloth; illustrated; price $2.50 net; 495 pages. P. Blakiston's Son & Company, Philadelphia.

LA BIOLOGIE SYNTHÉTIQUE. By STEPHANE LEDUC. Paper; 217 pages; illustrated. A. Poinat, Paris.

HOUSEHOLD BACTERIOLOGY. By ESTELLE D. BUCHANAN, M.S., and ROBERT EARLE BUCHANAN, Ph.D. Cloth; price $2.25 net; 536 pages; illustrated. The Macmillan Company, New York.

GENETICS. By HERBERT EUGENE WALTER. Cloth; price $1.50 net; 272 pages; illustrated. The Macmillan Company, New York.

PRISMS. By JAMES THORINGTON, A.M., M.D. Illustrated; cloth; 144 pages. P. Blakiston's Son & Company, Philadelphia.

PROCEEDINGS OF THE CANAL ZONE MEDICAL ASSOCIATION, for the Half Year April to September, 1911. Volume IV, Part 1. Paper; 238 pages. I. C. C. Press, Quartermaster's Department, Mount Hoep, Canal Zone.

## Medical Items.

**Water in Relation to Diuresis.**—D. Cow states that the amount of urine excreted after the ingestion of a given quantity of water depends (within limits) not only on the amount of water ingested but also on the fluid content of the tissues at the time. Water given by mouth and absorbed from the gastrointestinal tract is incomparably more active as a diuretic than the same quantity of water injected subcutaneously or intravenously. There is some substance, possibly of the nature of a ferment, which is taken up by water during the process of absorption from the alimentary tract; and this substance, either directly or indirectly, has a marked diuretic action.—*Proceedings of the Royal Society of Medicine.*

**Lecithin and Cholesterin and the Growth of Tumors.**—T. B. Robertson and T. C. Barnett conclude that cholesterin, whether suspended in dilute alcohol or in sodiumoleate solution, when injected directly into tumors causes a marked acceleration both of the primary and of the metastatic growth. The acceleration of the growth of the primary tumor by cholesterin is most evident in the premetastatic stage. Lecithin, when injected in the form of an aqueous emulsion directly into tumors, diminishes the tendency to form metastases, retards the metastatic growth when it does occur, and in some instances also retards the primary growth. The retardation due to lecithin is most evident in the metastatic stage. Simultaneous injection of strontium chloride solution into the tumors does not appreciably affect the action of the lecithin.—*Journal of Experimental Medicine.*

**Experimental Bone and Joint Tuberculosis.**—J. Fraser concluded from third experiment that direct infection of the medulla of a long bone is unlikely to lead to the development of a tuberculous osteomyelitis. Inoculation of the interior of a joint with tubercle bacilli readily produces tuberculosis of the synovial membrane. From such an infected joint the epiphysis or metaphysis of the bone becomes diseased. Infection of the arterial heart blood does not result in the local development of tuberculosis of the bones or joints. Infection of the main artery supplying a limb leads to the development of tuberculous disease of certain of the joints of that limb. Direct infection of the nutrient artery does not result in tuberculous osteomyelitis of the bone.—*Journal of Experimental Medicine.*

**Influenzal Encephalomeningitis.**—G. Rosenthal reports a case of this condition occurring in a boy seventeen years of age. The disease began suddenly with fever, headache, and vomiting and the patient rapidly passed into a semicomatose condition. Lumbar puncture revealed a clear cerebrospinal fluid which was not under excessive tension. It contained a slight trace of albumin, a few red blood cells, and a few altered polynuclear leucocytes. From this fluid there was isolated an organism having all the characteristics of the cocco-bacillus of Pfeiffer. Death occurred on the seventh day of the disease. Among the peculiarities of the clinical manifestations of this case were the absence of constipation, photophobia, and rigidity of the neck muscles. In view of the intensity of the headache, and of the nervous depression which terminated in coma, the author believes that the main pathological condition was an encephalitis accompanied by certain meningeal symptoms.—*Journal de Médecine de Paris.*

**The Local Action of Lead Upon the Intestinal Movements.**—P. D. Siccardi notes that in saturnism there is a diminution in the rhythmical intestinal movements and in the intestinal tone. This diminution is the result of the direct action of the lead upon the fibrocellular and muscular layers of the intestinal wall.—*Archivio per le Scienze Mediche.*

**Researches on Tubercle Bacilli.**—H. Petersen states that fresh potato furnishes an excellent culture-medium for tubercle bacilli. But tubercle bacilli of high virulence, such as the bovine, grow very poorly upon this medium. The intraocular vaccination of rabbits furnishes a ready means of determining the virulence of tubercle bacilli.—*Zeitschrift für die Tuberkulose.*

**Tubercle Bacilli in the Blood.**—A. de Verhizier employed a number of methods, including Rosenberger's and that of Staühli-Schnitter, in the examination of the blood for tubercle bacilli, in 15 patients affected with pulmonary tuberculosis. In no instance was he able to detect in the blood any of the microorganisms. He quotes Nicolle of the Pasteur Institute as follows: "The notion of a bacillemia in tuberculosis has been given too much prominence of late. In the majority of cases this bacillemia does not exist. The blood serum is so bactericidal that only in rare instances are the microorganisms present in the blood.—*Revue de Médecine.*

---

**The Hygienic Significance of Bovine Tuberculosis.**—A. Weber emphasizes the danger to human beings of tuberculosis in cattle. During childhood infection occurs not infrequently by way of the alimentary canal and may cause death through local changes or through systemic infection. In exceptional instances the alimentary type of infection may give rise to the usual forms of tuberculosis, both in children and in adults.—*Zeitschrift für die Tuberkulose.*

## Therapeutic Hints.

**Treatment of Gouty Migraine.**—The following prescription was recommended by Debout:

℞ Extract of colchicum, 3 grams.
Quinine sulphate, 3 grams.
Powdered digitalis, 1.5 grams.

This is to be divided into 30 pills, one of which is to be taken every evening.—*Bulletin Général de Thérapeutique,* April 8, 1913.

**Senile Neurasthenia.**—R. Oppenheim refers to the physical and psychical depression so frequently observed among the aged. In treating this condition the first requirement is to regulate the diet. This should be preferably one of milk, cereals, and vegetables. For the loss of appetite he gives:

℞ Tincture of condurango, 15 grams.
Tincture of gentian,
Tincture of calumba, āā 10 grams.

Of this mixture 20 drops should be given 15 minutes before meals. Or a tablespoonful of the following may be given in half a glass of water:

℞ Tincture of condurango, 2 grams.
Syrup of bitter orange peel, 120 grams.

The insomnia may be combated by means of simple hygienic and hydrotherapeutic measures. A good sedative is the following:

℞ Zinc oxide,
Extract of valerian,
Extract of hyoscyamus, āā 0.05 gram.

This should be administered in pill form before dinner and again 2 hours later. Once or twice a week the second pill should be replaced by a dose of the following:

℞ Trional, 0.75 gram.
Heroin hydrochloride, 0.005 gram.

This may be taken in a cachet, with a warm infusion such as an infusion of orange flowers.

The tonic treatment includes the administration of lecithin either by mouth or subcutaneously. Phosphide of zinc may be prescribed in the form of granules of 4 milligrams each, or as follows:

℞ Glycerophosphate of sodium, 0.25 gram.
Phosphide of zinc, 0.002 gram.

The hypophosphites may be administered subcutaneously. For this purpose there may be used ampoules containing the following:

℞ Calcium hypophosphite, 0.005 gram.
Sodium hypophosphite, 0.01 gram.
Potassium hypophosphite,
Magnesium hypophosphite, āā 0.005 gram.
Strychnine arsenate, 0.001.
Neutral distilled water, 1 c.c.

The contents of one ampoule may be injected daily.—*Le Progrès Médical,* April 12, 1912.

**The Treatment of Facial Hemispasm by Means of Local Injections of Magnesium Salts.**—Sicard and Leblanc have reported their results with this method of treatment. They have found that the good effects are only transitory, and are not to be compared with those following the local injections of alcohol in gradually increasing doses.—*La Presse Médicale,* April 9, 1913.

**The Use of Horse Serum in the Treatment of Tuberculous Lesions.**—Morel Cavallée reported at the meeting of the Medical Society of the Hospitals, of Paris, April 4, 1913, that he had obtained good results with the use of horse serum in the treatment not only of external tuberculosis but also of the early stage of pulmonary tuberculosis (*anémie prégerminative*).—*La Presse Médicale,* April 9, 1913.

### CONSULTATIONS WITHOUT SCARS.*

BY JOSEPH D. BRYANT, M.D., LL.D.,

NEW YORK.

THIS evening, with your indulgent permission and cooperative patience, I hope to interest you in a matter of pseudopathological interest, expressed, however, in an exaggerated sense.

Since scars are the common sequels of traumatism of the soft parts in every phase of active life, I am disposed this evening to utilize the fact in a metaphoric way, of course, as relating to the effect on the intracranial soft parts, of the unethical traumatisms sometimes inflicted by medical men on one another, while associated in professional consultations. As a rule, however, these peculiar traumatisms are inflicted by the thoughtless, sometimes by the assumptive, or by the absorptive, again by the assertive and vainglorious whose common aim in life to make a noise may be foretold, as is the thunder by the lightning flash. And it is fair to say, of the illuminating feature in these instances, that "heat lightning" followed or not by a faint response, may add something to expectation, or conclusion to vain desire, especially in dramatic instances. The outcome of a thoughtless act or of an absorptive desire, tinctured or not by studied effort, is somewhat the same in every instance, wherever medical brethren and patients are directly concerned. For, figuratively speaking, they all lie down together for a while; when apparently all arise to go forth, and lo! one is missing, and the strange sudden changes in the symmetry and proportions of one of the party point out the temporary abiding place and the fate of the missing one—the patient; who was absorptively and possibly in a benevolent spirit, transmuted from a post-primal case to one of quiet sinful abduction. In other words, not altogether unfamiliar, the consultant "bit the hand that fed him"; and, quite naturally, a scar of permanent and of painful kind was established where before friendship and trusting confidence were enthroned. The abiding sense of universal justice, going with fair play in every circumstance, is profoundly shocked when obliged to realize that faithlessness infects her followers, especially those who can no longer justly claim a right to the emulation that everywhere falls to the lot of just and honorable men.

I sometimes wonder what certain men would do were the law forbidding the stealthy absorption of other men's chickens made inoperative during the holiday time. This wonder is of course a relative one, and provides that then certain men may poach upon each other, the same as certain medical men now appear to do. Judging from current report and a little from vital experience, one is persuaded that more of unethical transgression happens every few days than one who is prompted by rare notions related to professional conscience, can willingly concede. The knowledge of unethical things is acutely infectious and rapidly spreads through the means of the specially sensitized atmosphere, abounding in phraseology rarely intended to encourage either the spread of truth or the correction of error.

It is no doubt fitting at this time to speak something of the ethical meaning of "consultations" as expressed in authoritative manner. Substantially, according to the Century Dictionary, "the deliberations of two or more persons with a view to some decision, especially a deliberation in which one party acts as advisor to the other" forms a consultation in the practical sense. In any instance this form of expression is of general application, as applied to the aim sought in medical consultations. Now, it seems suitable to introduce certain expressions borrowed from the Principles of Ethics of the American Medical Association, relating to the proper conduct of medical consultations. It is stated therein that: "In every consultation the benefit to be derived by the patient is of the first importance. All the physicians interested in the case should be frank and candid with the patient and the family. There never is occasion for insincerity, rivalry or envy and these should never be permitted between consultants." Again: "When a physician has attended a case as consultant he should not become the attendant of the patient during that illness, except with the consent of the physician who was in charge at the time of the consultation."

And just here it seems proper to remark that the consultant himself in these instances is not expected to "get busy" in calling this enlightening provision to the open-minded attention of those whom he would be pleased to favor in the thus artfully quickened though somewhat embarrassed state of mind of the friends of the patient. And, too, he should not assume control of the patient until after the former attendant has been released in a becoming manner. Personally, I have not yet attended a patient whom I had first served as a consultant, though not infrequently requested to do so. It is well in such instances, especially when tormented with acquisitive desire, to stop and philosophize a bit and thoughtfully repeat the wise expression of Aurelius:

"Never esteem anything as of advantage to thee that shall make thee break thy word or lose thy self-respect."

I am disposed to quote yet further, but briefly, from the Principles of Ethics relating to specialists in consultation:

"When a patient is sent to one specially skilled in the care of the condition from which he is thought to be suffering, and for any reason it is impracticable for the physician in charge of the case to accompany

*Paper read before the Practitioners' Society, April 4, 1913.

the patient, the physician in charge should send to the consultant by mail, or in the care of the patient under seal, a history of the case, together with the physician's opinion and an outline of the treatment, or so much of this as may possibly be of service to the consultant; and as soon as possible after the case has been seen and studied, the consultant should address the physician in charge and advise him of the results of the consultant's investigation of the case. *Both these opinions are confidential and must be so regarded by the consultant and by the physician in charge.*"

Apropos of the foregoing text, a foreign close friend of mine in many ways, related to me some time ago the following experience which he regarded as falling quite naturally under the fostering care of the Ethical scripture just recited. In this instance, he said, a young, intelligent and long devoted female patient afflicted with temporary deafness of one ear with roarings of annoying kind therein, came to him for relief. Because of discreet and obvious ethical reasons the patient was given an explanatory note to a distinguished aurist with the request only that he make careful examination of the mechanism of the ear, and that a written report thereof be returned by the patient. Accordingly the patient promptly presented to my friend an open note of the consultant, held with trembling fingers, containing a prescription and the further knowledge that he was going to test the blood on the following day for the hemaglobin content. The patient was frightened, indeed, by the uninvited conversational and written announcements of the consultant and most respectfully declined to remain in or go further in that direction. Had the consultant limited his activity to the written request, my friend and the patient would have been spared much annoyance and the consultant himself, of being notified that the blood had been examined in all essential respects the day before his special services were requested. The consultant surely indulged in needless activity, perhaps, however, from a misunderstanding. In any event, he learned that, according to the philosophy of Epictetus, "That everything has two handles, one by which it may be borne, another by which it cannot."

Another unethical instance worth the telling happened in the experience of a colleague of mine, who referred a wealthy patient afflicted with a localized, very annoying prurient ailment, to an eminent consultant, especially learned in the treatment and cure of such troubles. The learned gentleman, after careful examination of the case in all respects, predicted a prompt cure and took entire charge of the patient. The affliction, however, proved far more stubborn than had been estimated, whereupon the consultant thoughtfully explained to the patient substantially as follows: "I could have cured you before this had you fallen under my care at the outset of the trouble." Following this remark, the patient in a shrewd though innocent fashion, said to my colleague, "Our distinguished physician not being as smart as he thought, seems inclined to divide the responsibility with you and me, which I thought you ought to know." To my colleague in this instance it seemed that more was "meant that met the ear" and therefore, as he some time ago informed me, "The itching spots in my practice have since been referred for treatment to a more thoughtful and perhaps more skilled authority." Not a large nor troublesome scar resulted from this consultation, but a disfigurement of ethical confidence followed, to which such parentage should not have given birth. The following case is of interesting nature in ethical matters.

In this instance a young, earnest physician devoid of guile and who regarded others of his profession to be like himself, as fair and honorable in all respects, requested a consultant of honorable report to see a case without his presence, because of a sudden imperative demand which he himself could not forego. Also, he expressed to the consultant in a brief sealed note his ideas of the illness and his plan of treatment, in a requisite manner. For the purposes of this instance, it is only necessary to add that the consultant received this note at the hands of the patient in question. The note was read by the recipient and the patient was carefully examined. Immediately thereafter the consultant in a note of his own, expressed views adverse to those of the physician who had called him in the case, in all essential respects. And for some reason or excuse the enclosure, though properly addressed, was left for the attending physician on a nearby table—unsealed. It should be quite apparent that no reasonable degree of human restraint of personal nature could have been quite sufficiently powerful to prevent the patient or the friends, in this seductive instance, from digital transgression on the sacred confines of that frankly fashioned and openly adjusted envelope. Whether or not depraved intrusion was practised I do not know, but do know what I believe, for according to Montaigne "nothing is so firmly believed as what we least know." And, as corroborative evidence of the soundness of my faith, soon after this a readjustment of the medical personnel in that particular family came to view; the family physician going an the retired list and the consultant taking command. Whether or not the open note was premeditated, hence viciously unethical, or due to thoughtlessness, paucity of salivary secretion, or to the stationer's thrift or carelessness, I am not able to declare, but the prompt corroborative activity displayed by the mutually interested parties and the effective results, incline me to know what I believe, and, therefore again I will anchor my faith to the wisdom of Montaigne. Unethical offenses of this kind are indeed few because of the sparseness of practitioners thus disposed. The scars, however, incident thereto and those of ethical offenses of lesser magnitude, are readily seen and estimated by their repugnant aspect, both by the profession and the lay public. The self-respect of the former, and the admiration and confidence of the latter, are thereby stricken with an abiding sense of disfavor and distrust.

The kind of consultation thus far noted may, for the purpose of differentiation, be designated as "domestic or household consultation," and therefore is of special social importance. In contradistinction to this class another, styled "official consultation," applicable to hospitals, prisons, etc., and usually dignified by "an order of the court," or, by the desire of one of highly exalted station, is adapted for the purposes of similitude. Whether or not either of these brief momentous entanglements begets the right or the privilege on the part of either physician included in the case, to disregard the ethical features of a common medical consultation is, I dare say, a matter open to discussion, for it is claimed that some physicians in either of these circumstances too often act regardless of established ethical relations respecting the patient, the friends, and even the medical brother in charge; other physicians, so

far as is possible, show their good breeding in these circumstances by ethical conduct like that decreed for ordinary consultation. I fear, however, that those who would disregard proper professional conduct in the one instance doubtless would sin correspondingly in the other. For, "How use doth breed habit in a man" was long ago told by Shakespeare.

An old friend sadly complained to me not long ago, saying that a "self-sufficient medical examiner empowered by the court" and "propelled by vain desire" had needlessly and offensively gained access to a patient in a private room of a public hospital, and had examined the patient without the knowledge or consent, or even the expectation, on the part of any one of the various medical men of the hospital connected with the case. Surely the law contemplates that its agents shall, when possible, act in an orderly ethical manner, and consequently in accordance with the accepted rules and regulations of civilized control of hospital and penal institutions. Not, however, in obedience with the whims of unduly inflated medical agents, whose assumptive importance is likely over-estimated in these, as perhaps in other professional activities.

For the privilege of recital of the following apt example I am indebted to a physician of long standing with whom, now and again, I had had intimate friendly and professional relations. The interesting and unusual incident in question especially relates to an exalted personage, of the highest official station, who desired information related to health of a convict who was confined in prison for a crime against the government. According to my friend, a physician who then resided not one hundred and fifty miles from here, was unofficially requested by the President of the United States to examine the prisoner at the earliest convenience as bearing on his physical state, with the view of pardon. It was requested that the examination be made quietly, so as not to further stimulate the hopes or fears of family and friends, and, incidentally, of those who, for various other reasons, might be profoundly interested. The physician bearing a presidential letter of introduction to the warden of the prison promptly came into action. Then it was that this physician was told that the medical officer in charge of the prison was in bed at home, because of illness. The latter officer, however, over the 'phone, gave permission for immediate examination, but on inquiry expressed the hope that he could be present on the morrow. For this reason the examination was accordingly deferred. But as the morrow afforded no relief to the medical officer, he in a written communication desired that the examination be no longer delayed, and that he be favored with a report of the findings and the conclusion. This request was complied with, and both were freely and favorably discussed by the physicians. It appears that, as the result of these ethical attentions, the report to the President himself was delayed for about twenty-four hours, but without any physical detriment whatever, as could be easily foretold. As my friend finally remarked in the telling of the aforegoing, "You will observe an abundance of words in this narrative, and, perhaps, without adequate reason therefor, but the few more that follow will leaven the whole and justify the exercise of scrupulous care in ethical ways, even in pondrous instances. For," said he, with pronounced emphasis, "the indisposed physician in charge was grateful, indeed, for the unexpected ethical courtesies shown to him, and the President, too, when advised of the reasons for the brief delay, said, 'You did exactly right, just as I would expect under the circumstances.'" That this visiting physician was happy and profoundly gratified with the outcome, further said my friend, needs no proof and the moral is plain. Do what is right, for, according to Abraham Lincoln, "right makes might."

Since it would seem that sufficient has been said already to establish the equity of the ethical principles thus far expressed, we might now well turn briefly, without illustrations, to the ethical relations of one physician to another's patient. In this matter I bespeak your careful attention and prudent thought to the following extract from the Principles of Medical Ethics of the American Medical Association, for it is in such instances of unethical offence that the profoundest sinister impressions are made upon the minds of the lay members of society:

"The physician, in his intercourse with a patient under the care of another physician, should observe the strictest caution and reserve; should give no disingenuous hints relative to the nature and treatment of the patient's disorder; nor should the course of conduct of the physician, directly or indirectly, tend to diminish the trust reposed in the attending physician."

In directing your attention to this self-evident ethical doctrine, I, perhaps, needlessly remind you that the word *ethical* is the lawful offspring of the somewhat more formal expression—Ethics. This latter expression, in the reminiscent thoughts of yet many of our ilk, has not altogether a cheerful sound. And especially is this true of those whose memory links it with the word "Code"—"Code of Ethics"—a dual combination now obsolete, but formally for a time, associated with vigilant, robust contention on the part of the real and pseudo giants of our profession.

The need for "principles of ethics" was denied or disregarded by many, indeed, of our profession and decidedly so by those whose natural inclinations were opposed to the notion that they themselves and others like them in this respect needed a guiding light of special human kind to direct or remind them of a proper way to treat those whose aims and objects run near together and parallel with their own, therefore with the natural tendency to collide. I have heard it said, less of late than before, as likely have many here, that good breeding, good sense and the inherent comprehension of one's duty to his professional kind in ethical need, make special guides to the purpose oppressive, humiliating, and not of any use. That they themselves can better avoid and adjust such experiences at their birth and in the period of their activity, through the inherent sense of justice than through the agency of prepared and predigested principles of action, printed, bound, and promulgated for this special purpose. Such as these are quite unmindful of the force of the common truth, that established plans of action are the foundation of commendable success; and that hasty action too often breeds confusion and distrust. Is it not certain, however, that one whose acts are prompted both by acquired and inherent justice need have little fear of just rebuke from anyone? As yet how keen may be the smart of some who more than a quarter of a century ago opposed with bitter zeal the code of medical ethics, and of some who less than ten years ago opposed the change from "the code of ethics" to the "principles of ethics," by State referendum, with an affirmative vote of over 3,300 to a negative of 197. It is not strange, and in fact quite

natural, that some of those who "bore the burden and heat of the day" in ethical contests, are yet not quite reconciled to the outcome and have a lurking smart akin to that which at times seems keenly to touch the hearts of a proud and honest people, long after the close of fraternal strife.

The aforegoing illustrations of ethical lapses of our profession, emphasize in no uncertain way the need of the coordinating and restraining of the open and hidden forces that would thus determine our actions, as opportunity affords. The coordination of aggressive strength, restrains the forces that would beget and support physical and moral servitude. The coordination of dissimilar forces determines for honorable action. So long as devious fields of human effort and ambition shall have pleural membership, sooner or later restraining control will be needed to maintain and promote a proper sense of equity and a suitable regard for the rights of each member. The demands of necessity, the dictates of custom, and the besetting influences of desire or determination, cause wondrous changes in social order in brief, unexpected, and surprising ways. Consequently, it would seem wise that rules of action in special things should be established and reasonably employed in the settlement of common differences, and, better yet, in the prevention of distrust and dissension in the ranks of our profession. As was some time ago pointed out by the writer, the effct on the lay mind of the unethical practices of the members of our profession is a matter of such importance that it would seem proper to admit that the station of medicine in the estimation of many thoughtful people is not quite up to that of other learned callings closely relating to the comfort and welfare of the body politic, notably those of theology and law. And when one unbiasedly estimates the degrees of esteem exhibited by the public for the learned avocations, it is hardly possible to persuade oneself that the medical profession yet enjoys equal station with that of the others already mentioned. I am not ignorant of the fact that impassioned pleadings, embellished by sublime sentiments, are, on state and social occasions, given birth by eloquent tongues and facile pens, prompted by grateful appreciation of the beneficence and glory of the medical calling. Nor am I blind to the truth that comparatively humble, silent tributes of similar regard are more numerous than the former, and also, that because of their earnest halting fervor they often give stronger evidences of gratitude than do those blessed with ampler expression. The modest homage indicating the gratitude of the humble is usually more wholesome and abiding than that pictured by the fervid assurances of those of higher station. That esteem and thankful good-will should be a large part of the rewards of our profession is both proper and just, and will maintain so long as life and comfort rule the senses of mankind. And few, indeed, there are whose experience with the somber side of life's physical trials, who would not gladly give enthusiastic approval of these sentiments. And the lower creatures, too, often instinctively testify of their delight and love by caressing the hand that mitigates their distress, or by championing the cause of one who comforts them in disaster.

The influences of adverse nature contributed by members of a profession itself obviously play an important rôle in fairly estimating professional standards. The degree of sincerity evinced by the members of a profession by the promptness and equity of the adjustment of their ethical affairs and the absence of discourtesy exercise a profound influence on the sayings and feelings of those of less pretentious engagements. It is properly asserted that a chain is no stronger than its weakest link, and by the same standard of measure, the station of a profession can be estimated by the character and conduct of its constituents. The standard of the civilization of a nation is often misunderstood, because of the conclusions of unripened judgments based on the repellent examples of its constituents that occasionally come into view.

Too frequently, for the dignity and station of our profession, one hears complaining utterances of disappointed members whose estimates of success are often measured more by a greed for vulgar gain than by the desire for a wreath because of benevolent endeavor. The hunger of unrequited ambition for recognition, begetting pessimistic fault-finding and ungracious speech, supplemented by invidious claims of the disgruntled and the loud clamors of the self-assertive for those things which by common consent men gain from merit, are often as discomforting and degrading as they are pitiful.

That the kind spirit of a gracious and loyal membership perpetuates an unscarred advancing status in medicine, is as well known to lay people as that unethical and restless membership inhibits or scars the progress in commendable things in all forms of human endeavor. And, when it shall be possible for the members of our profession to keep step with the constructive harmony begotten and sustained by the precept of the Golden Rule, then will the need for a rule of Medical Ethics have become for the time a needless, empty requirement.

## OSTEITIS DEFORMANS (PAGET'S DISEASE).*

By W. GILMAN THOMPSON, M.D.,

NEW YORK.

Sir James Paget in his original memoir on osteitis deformans presented a study of five cases in November, 1876, before the Medico-Chirurgical Society of London, to which he added seven more in the Transactions of that society in 1882. In a review of the literature in the *American Journal of the Medical Sciences* in 1901, Packard was able to collect sixty-six cases reported to that date. This list was augmented by Higbee and Ellis who found 158 cases reported prior to January, 1911. Since that date S. F. Jones has described in the Medical Record of December 28, 1912, another case occurring in a young woman, so the case herein reported may be regarded as the one hundred and sixtieth.

This case, shown in the accompanying illustrations, is that of a woman who entered the Cornell University Medical Clinic in Bellevue Hospital in the latter part of January, 1913. She is 60 years of age; a native American; employed in general housework. Unfortunately her mind is so childish that it is impossible to obtain any history from her which is of the slightest value. For example, she attributes her bone deformities to fractures, claiming to have walked around with a newly fractured thigh six years ago, without surgical treatment! She admits, however, that when 15 years of age her head appeared uncommonly large, and that she ceased menstruating at 40 years of age. She ap-

*A case reported to the Practitioners' Society, April 5, 1913.

pears further to have had the general pains in the extremities which characterize the early stages of the disease, but they have long ago ceased, nor has she at the present time any subjective symptoms whatever, having entered the hospital for an attack of bronchitis which completely subsided.

Upon examination the deformities of the cranium, pelvis and bones of all the limbs are very striking. The following measurements were recorded.

Total height, 145 cm.; crest of ileum to heel, 83 cm.; crest of ileum to vertex, 62 cm.; acromium to tip of middle finger, 64.5 cm.; circumference of thorax at nipple line, 74 cm.; circumference of head, 58.5 cm.; arch over vertex between ears, 31.5 cm.; arch over forehead between ears, 31.5 cm.

The patient exhibits a slight dorsal kyphosis. The pelvic brim is wide and the abdomen is protuberant and globular—the *ventre de batracien* of the French writers. On attempting to stand erect with the legs in the natural position, they present such extreme elliptical outward bowing that the knees cannot be approximated within 10 cm. and the feet are everted almost at right angles to the normal position. Hence the patient cannot balance herself in the normal erect attitude but manages to walk by crossing the right leg in front of the left, thus forming a figure-of-eight as shown in the accompanying picture, Fig. 1. The femora are markedly bowed outward and forward, after the usual manner of this disease, and the accompanying *x*-ray, Fig. 2, shows them to be irregularly hypertrophic, being thickest in the upper two thirds, and thinnest at the junction of the middle and lower third. The humeri, particularly the left one, are in like manner bowed outward and irregularly hypertrophied, Fig. 3. The bones of both forearms and legs and the clavicles present similar enlargement and distortion, but in lesser degree. The ribs are unaffected, as well as the bones of the hands and feet. The cranial vault is exaggerated and the parietal and frontal bones especially are broad, thick, and grossly uneven on the surface. The postero-temporal and parietal regions are so prominent as to depress the ears and give the face and head a wedge shape. This is accentuated by a narrow-pointed protuberant inferior maxilla. Such an extreme case is easily distinguished from rickets. There is no deformity of the sternum, beading of the ribs, enlargement of the epiphyses or craniotabes, and the *x*-ray pictures are diagnostic in showing the irregular hypertrophic osteitis, particularly of the cranium, humeri, and femora. Furthermore, the disease has developed during adult life.

The general health of the patient is excellent. She is entirely free from pain or tenderness over the affected bones, and the detailed physical examination of the viscera reveals no abnormality excepting in the heart a slight mitral regurgitation. There is, however, advanced arteriosclerosis and the blood-pressure averages 170 mm. There is no abnormal pigmentation of the skin or hypertrophy of the soft parts such as is usually observed in acromegaly. The Wassermann reaction is negative.

None of the numerous theories to explain the origin of osteitis deformans has met with general acceptance. It is true that a majority of those who have studied the few recorded cases, led by Lannelongue and Fournier, have favored the idea that it arises from hereditary syphilis, and the theories of its origin in trauma, a rheumatic diathesis, a trophoneurosis, or sclerosis of the nutrient arteries, have been abandoned. But the chemical analysis of the bones in syphilis and osteitis deformans is quite different, and the progress of the latter disease is not decisively modified by antisyphilitic treatment, nor is there any very definite evidence in the majority of cases that the lesions are parasyphilitic manifestations. Attempts to refer the disease to disordered functioning of the thyroid, suprarenal or pituitary bodies have similarly failed of confirmation in most of the autopsies recorded, although in one or two cases there have been found changes in the pituitary body.

Paget called attention to the coincidence of malignant disease with osteitis deformans, and five of eight patients, whose life histories he obtained, died of sarcoma or carcinoma. But this form of osteitis

Fig. 1.—Osteitis deformans, showing bowing of legs and the only position in which standing or walking was possible.

is very chronic and often is not established until late in life when malignant disease is common. Moreover, in a study of the 158 cases recorded prior to January, 1911, Higbee and Ellis were able to discover only fourteeen instances of malignant disease. The following year another example of the combined diseases was reported from Montreal by Gruner, Scringer, and Foster, occurring in a male 56 years of age. (*Arch. of Internal Med.*, June, 1912. Vol. 9, pp. 641-656.) In this case, however, 6 years elapsed between the appearance of the osteitis and the sarcoma and the sarcoma invaded only a few of the many bones involved in the osteitis. In this case, also, it is interesting to note, there was marked atrophy of the pituitary body.

All arguments considered, the conclusion of André Chastel, who reports two cases in his Paris Thesis of 1910, appears justified, namely, that osteitis deformans is an independent, well-defined disease, "the theory of the etiology of which has yet to be established." In the few cases in which metabolism observations have been conducted, nothing distinctive has been determined, possibly because they have not been conducted over long enough periods for so chronic a disease.

The most comprehensive study of the disease published since Sir James Paget's original account is given by Jules Vincent in his Paris Thesis of 1904, (Maladie ossieuse de Paget) in which he presents an interesting discussion of previous articles, and includes eight new cases, several of which are pictured. This writer, emphasizing the early nerve symptoms of the disease, namely the muscular cramps, fatigue pains, exaggerated reflexes, and occasional incontinence of urine and local hyperthermia, inclines to the hypothesis that the disease may originate as a central trophoneurosis, although in the few autopsies which have been made, a thorough study of possible pathological changes in the nervous system has not been undertaken. Following is a brief summary of the pathological anatomy of the disease as given by those who have opportunity to perform necropsies.

The muscles attached to the affected bones are pale and atrophic, and the ligaments occasionally have been found ossified. In the earliest stage of the disease the bone tissue appears somewhat soft and fragile, but as the disease advances it becomes firm. The periosteum may remain normal or exhibit increased vascularity. In stripping it, adjacent portions of bone tissue are sometimes detached.

Fig. 2.—Showing bowing of left femur, hypertrophy of upper portion and rarefaction in lower third

The bone tissue becomes porous through enlargement of the superficial Haversian canals. The central medullary canal becomes rarefied. The surface of the long bones is frequently uneven or mammillated, and the normal bony prominences are exaggerated. Here and there are small areas which are so friable that they may be indented by firm pressure with the finger. The affected bone thus becomes uneven in surface and more or less nodular and spongy.

The diaphyses of the long bones become voluminous through exaggerated development of the

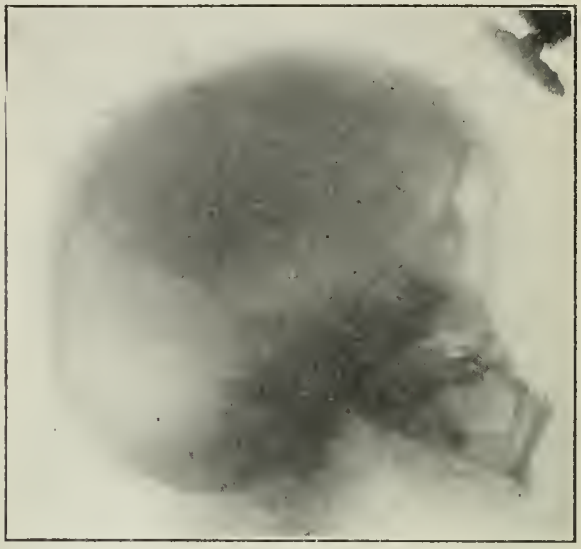

Fig. 3.—Showing breadth of calvarium and increased thickness.

compact substance although at the outer surface, and near the medullary canal, the bone is more or less rarefied. In the intermediate zone of the long bones there are islands of tissue which remain firm and solid. In parts the vascularity appears increased. The medullary cavity becomes irregular in form, being here and there dilated, and elsewhere encroached upon by new bone formation. The marrow is vascular and red, resembling that of fetal bone. The spongy tissue of the epiphyses is rarefied, and at the cartilaginous surface sometimes presents fatty degeneration and necrosis.

The external surface of the cranium presents large elevated plaques. The inner surface is smooth or finely granular. The sutures are obliterated. The bones at the base of the skull are usually not thickened. On section the diploë is found to have disappeared, and the remaining tissue presents an irregular structure of alternating areas, some of which are spongy, others as dense as ivory. The ribs have occasionally been found to present rarefaction and their cartilages may be partially ossified.

Microscopically there is seen a progressive absorption of the bone tissue in the vicinity of the medullary cavity and Haversian canals, with a compensatory formative osteitis, and beneath the periosteum large porous periostoses.

---

**Tubercle Bacilli in the Blood in Surgical Tuberculosis.**—M. Krabbel, employing Schnitter's method, was able to detect tubercle bacilli in the circulating blood in 12 out of 18 cases (66.6 per cent.) of bone tuberculosis; in 1 out of 5 cases (20 per cent.) of gland tuberculosis; and in 1 out of 4 cases (25 per cent.) of skin, mucous membrane, and tendon tuberculosis. The smaller proportion of positive findings in gland tuberculosis in contradistinction to bone tuberculosis is explained by the fact that in the former condition the process is largely a local affection from the mouth and tonsils, while in bone tuberculosis the tuberculous material gets into the blood stream. The demonstration of tubercle bacilli in the blood in cases of surgical tuberculosis may be of eminent diagnostic value in cases that do not give any evidence of pulmonary lesions. —*Deutsche Zeitschrift für Chirurgie.*

# THE FUNCTIONS OF THE PINEAL GLAND.*

By CHARLES L. DANA, M.D.,

AND

WILLIAM N. BERKELEY, M.D.,

NEW YORK.

WITH REPORT OF FEEDING EXPERIMENTS.

By H. H. GODDARD, Ph.D., AND WALTER S. CORNELL, M.D.,

VINELAND, N. J.

INTRODUCTORY, BY DR. DANA.

A SUMMARY of the various theories regarding the functions of the pineal gland is given in W. v. Bechterew's "Die Funktionen der Nervencentren," vol. 2, page 1182, 1909. This author presents also an account of its anatomical relations and some notes of pathological observations bearing on physiology.

An account of the comparative anatomy of the gland is given in Wiedersheim's "Comparative Anatomy," pp. 202 and 205, 1908.

The phylogeny of the gland is fully discussed by Prof. Patten in his recent important work on "The Evolution of the Vertebrates and Their Kin," pp. 113 and 136, 1912.

A summary of the anatomy and functions of the gland and of recent experimental work upon it is given in Swale Vincent's work on "Internal Secretion and Ductless Glands," p. 405, 1912.

The symptomatology of the tumors of this gland is given, together with a summary of recent literature, in a valuable monograph by Bailey and Jelliffe on "Tumors of the Pineal Body" (*Archives of Internal Medicine*, 1911).

The recent appearance of the above literature makes it unnecessary to go into an extensive review of the subject here. What is known at present of the pineal gland comes from the following sources: experiments on animals, experiments with extracts of the gland, clinical and pathological studies, and a consideration of the embryology and phylogeny. Dixon and Halliburton (*Quarterly Journal of Exp. Phys.*, 1909, ii, p. 283) found that intravenous injections of the extracts caused lowering of blood pressure. Cyon (Die Gefässdrüsen, p. 226, 1910) found such injection in small doses had no action on blood pressure. In large doses the heart beat increased in strength and became slower and irregular.

Ott and Scott (Ott's Contributions to Physiology, Part XIX, 1912) state that pineal extract causes vasodilatation in the genitalia of male cats. Ott also states that the aqueous extract causes first a fall and then a rise of arterial pressure, that it stimulates intestinal movement, and also the contractile power of the uterine muscle; that it causes glycosuria in rabbits. (*Monthly Cyclopedia and Medical Bulletin*, September, 1911). Ott also found (Contributions to Physiology, Part IX) that it caused diuresis and increased volume of the kidney through vasodilatation. Eyster and Jordan (*American Journ. of Phys.*, xxvii, 4) found that the aqueous extract of the pineal body of sheep caused a fall of the mean arterial pressure by dilating the intestinal arteries; also that it caused temporary diuresis.

FIG. 1.—Showing pineal gland (X), and its relations

Cyon stimulated the pineal body of rabbits and produced changes in its form and position due to the presence of unstriated muscle in this organ. He thinks that the gland may act mechanically in controlling the flow of cerebrospinal fluid through the aqueduct of Sylvius and may thus have some function in regulating intracranial pressure (*Pflüger's Archiv*, 1903, xcviii, p. 327). This seems a fanciful theory and can hardly apply to man, for I find no description of muscular fibers in the human pineal, though Nicholas (*C. R. Soc. de Biol.*, Paris, 1900) and Dimitrova (*Thèse*, Lourain, 1901) describe a number of muscle fibers in lower mammals.

Exner and Boese (*Deutsche Zeitschrift für Chirur.*, 1910, cvii, p. 182) destroyed the pineal gland in 95 adult rabbits. Twenty-two animals survived and were observed for some time, without any change from the normal.

A study of the *clinical history and pathology* of

*The work described in this report was greatly aided and largely accomplished by a grant from the Rockefeller Institute.

the gland leads to more definite results. Hempel, in a case of cancer of the pineal gland in a man of twenty-four, observed the development of obesity, followed by marked atrophy of fatty tissue (cancer cachexia?).

Marburg reported the case of a patient who had marked obesity. There was a mixed tumor of the pineal, the hypophysis and other blood glands being normal.

In Raymond and Claude's case the patient, a boy of ten, became fat and large for his age. Autopsy showed a glioma of the pineal.

In Frankl-Hochwart's case, a boy of 5½ was stout and tall for his age and at five had reached the size of a boy of nine or ten, with marked premature development of the genitals. He was also precocious mentally. The lesion was a teratoma of the pineal, the size of a walnut (5 by 2.5 by 2.9 cm.).

In Oestreich and Slawyk's case, a child of four grew rapidly, and the genitals were enlarged. The lesion was a cystic psammo-sarcoma of the pineal.

Heubner reports the case of a boy of 4½ years with excessive and premature body and genital development.

Ogle's case was that of a young boy with excessive and premature development of the genitals.

In Gutzeit's case, a boy of 7¾ showed undue bodily development.

Pelizzi reports two cases with precocious physical and genital development. He calls the pineal syndrome macrogenitosomia (*Revista ital. de neuropat.*, 1910).

Among 57 cases collected 13 occurred in children of 13 years of age or younger. Among these in two there were no notes. Of the remaining, all but one showed some disturbance of growth.

In nearly all reported cases there was increased intracranial pressure and often involvement of the corpora quadrigemina and adjacent parts. Intracranial pressure alone, however, as we see it in hydrocephalus from various causes, including the different kinds of brain tumors, does not lead to obesity or premature genital or somatic development. Thus it seems that the literature of the diseases of

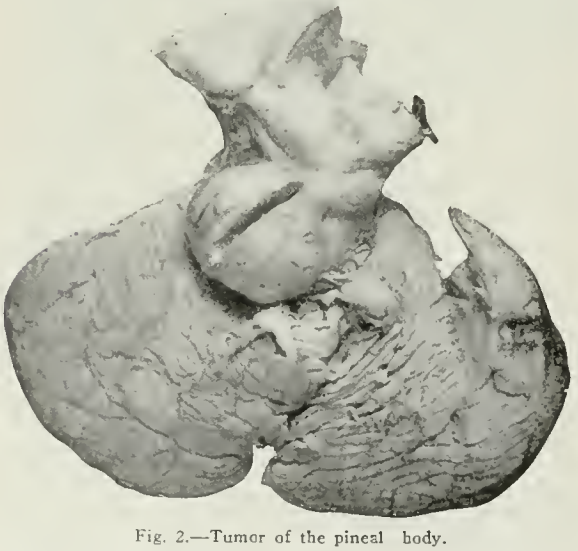

Fig. 2.—Tumor of the pineal body.

the pineal gland gives some evidence that lesions of this body, occurring in the young, cause peculiar disturbances of nutrition, such as increased growth of adipose tissue, stimulation of the development of the sexual and of the somatic and perhaps mental functions.

*Embryology and Phylogeny.*—In order to justify the further expenditure of time and money on what is generally thought to be a vestigial and functionless organ, I submit some facts regarding the origin of this gland.

The embryology of the pineal gland, with certain

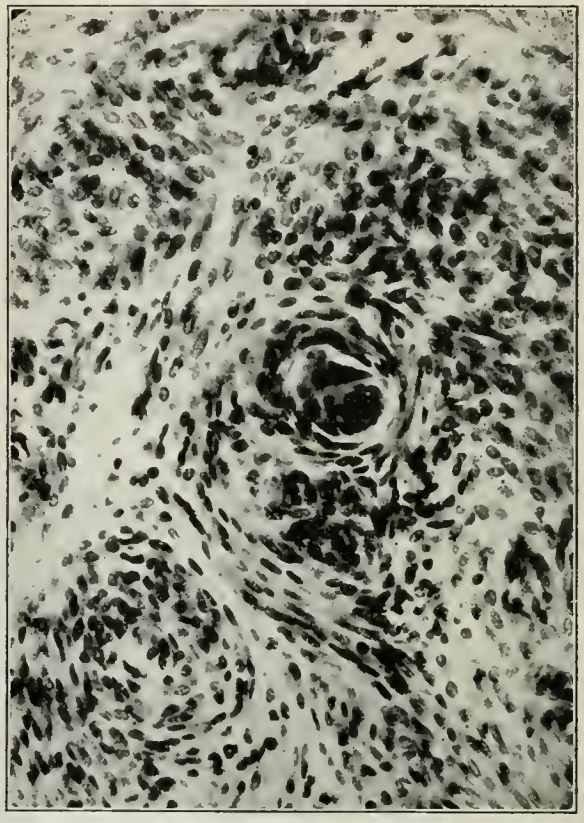

Fig. 3.—Tumor of the pineal gland. (F. C. Wood.)

suggestions as to its function, has been carefully studied in the last ten years, and the results given in a succession of five papers which have appeared in the *American Journal of Anatomy*, as follows: 1. C. S. Minot, 1901. 2. "The Paraphysis of the Common Fowl," F. Dexter, 1902. 3. "The Development of Paraphysis and Pineal Region in Necturas Maculatus," Dr. Warren, 1905. 4. "The Morphology of the Pineal Region in Teleosts," R. J. Jerry, 1910. 5. "The Development of the Paraphysis and Pineal Region in Reptilia," Dr. J. Warren, 1910-11.

PATHOLOGICAL AND PHYSIOLOGICAL EFFECTS ATTRIBUTED TO THE ACTIVITIES OR DISORDERS OF THE

| Pituitary Body | Pineal Body |
|---|---|
| Adiposity | Adiposity (later sometimes a marked atrophy of fatty tissues) |
| Sexual changes | Early development of sexual organs and functions |
| Genital atrophy and infantilism | Early bodily and mental maturity (Macrogenitosomia of Pellizi) |
| Acromegaly and gigantism | *Physiological action of extracts of the gland* |
| Polyuria | Contradictory reports as to pressor and depressor effect on blood-vessels. |
| Control of carbohydrate metabolism | Stimulation of unstriped muscular tissue of intestines, uterus, pupil |
| Lowered temperature | Vasodilatation of genitalia and kidney |
| Coordinate action with other glands | Transitory diuresis |
| *Physiological action of extracts of the gland* | Glycosuria |
| Pressor and depressor effects on blood-vessels | Stimulation of metabolism(Berkeley) |
| Galactagogic effect | |
| Stimulation of muscles of pupil, uterus and intestines | |
| Modifications of metabolism and bodily growth | |
| Modification of carbohydrate metabolism | |

Prof. Minot states in his article in 1901 that "The pineal region"—that is, a certain portion of the roof of the forebrain, "shows a series of structures which from their anatomical characteristics appear to be distinctly concerned in the formation of a fluid in the cavities of the brain." "We may assume," he adds, "that the choroid plexus supplies the main bulk of the fluid, but the gland-like origin of the epiphysis and paraphysis indicate that they supply with various chemical substances the encephalic fluid."

Dr. Minot adds that it is for the physiologists and pathologists to determine what the function of this fluid is.

The pineal gland is given great attention by Prof. Patten in his recent original and important work on the "Origin of Vertebrates." He there discusses the phylogeny of the epiphysis, and gives to this organ great significance in the development of invertebrate into vertebrate life. He shows that the pineal gland is, as has been usually taught, a vestigial eye—an eye that had function in late invertebrate and early vertebrate life, when it forms what is known as the parietal eye. "This eye as a functional organ is," Prof. Patten says, "the most ancient of all sense organs and becomes a characteristic in the early history of the arachnid phylum."

The vertebrates all have remnants of such a parietal or median eye developed from the second neuromere, while the lateral or present functional eyes are developed from the third or fourth neuromere. This parietal eye of vertebrates is homologous with the parietal eye of arthropods. In these latter animals this eye was an important visual organ until the lateral eye developed. During the evolution of arachnids into vertebrates there was a period when the parietal eye was a functioning organ. These vertebrates were monoculate and depended solely on this parietal eye for vision. The parietal eye is the only one now present in tunicates. In the oldest ostracoderms the lateral eyes are absent or nearly so. In lampreys the parietal eye is well developed in the larvæ, while the lateral eyes are functionless.

The parietal eye was originally a double organ and the *ganglia habenulæ* of vertebrates represent the ganglionic roots of the ancient parietal eyes of the arachnids. While the embryology of the pineal eye indicates plainly that it is the vestigium of an old visual organ, there is no evidence of the existence of special sense structure even in a rudimentary form in the anatomy of the pineal gland in the human embryo. The secretory or metabolic functions of the gland if present are due to supplanting tissues, epidermic or vascular, not to any special sense residuum.

The pineal gland in man has become distinctly a glandular organ with secreting cells and probably a few nerve fibers. It tends to undergo deterioration at about the seventh or eighth year, but up to that time it may be supposed to have some function.

*Experimental.*—The experiments carried out by us were the following:

1. The nucleoproteids and entire gland extracts were obtained and injected into the veins to test the effect on the blood pressure.

2. They were also injected into young animals—rabbit, guinea-pigs—for a long time to determine the effect on nutrition.

3. The whole gland was fed to young animals.

4. The whole gland was fed to defective and retarded children.

It was agreed that only the glands of young animals would be worth while experimenting with, and Dr. Berkeley made arrangements to secure the glands of young bullocks. He obtained the nucleoproteids of the pineal gland and made experiments with them by injecting them into growing guinea-pigs and he tested the pressor qualities of the gland by injecting it into veins of the dog. The details of his results are given by him.

Since the beginning of the summer of 1911 the investigation has been confined almost entirely to feeding experiments. Dr. Berkeley has been feeding guinea-pigs and rabbits, and he and I also have been feeding the gland to certain selected children. Our plan was to feed it only to young children if possible under eight or nine years and to children who seemed to be cases of simple retardation without notable anatomical defect and without epilepsy. Children in the retarded grades of the public schools were used for this purpose as well as private cases.

As a work of this kind would take a long time before we could reach results, we conferred with Dr. Goddard, of the New Jersey Training School for the Feeble-Minded at Vineland, New Jersey. Dr. Berkeley supplied the gland and Dr. Goddard and Dr. Cornell undertook to use it. They fed the gland to twenty-one children, watching these and comparing them with twenty-one controls. This work was carried on for nearly eight months. There seemed to be such definite results that we have thought it worth while to make a preliminary communication concerning what has already been done.

Dr. Berkeley tells in his article of the apparent good results and of the enthusiasm aroused by the use of the gland among the teachers of certain backward children in a New York school.

The research is not finished. We hope to do more experimental work and continue the feeding experiments, but it seems that the immediate merits of the matter might be discovered more rapidly if the facts so far proved were known; hence we have decided to make this preliminary communication.

Our provisional conclusions may be stated as follows: The pineal gland is the vestigium of a special sense organ of vision in invertebrates and certain low vertebrates. In man it has practically lost all the structural characters of a sense organ and has those of a glandular body. It undergoes some involution at about the seventh year of life.

We are strongly of the opinion that in the early period of life it has influence over bodily nutrition, including the development of the genital organs, the deposit of subcutaneous fat, general growth, and mental progress.

We find that the extract of the pineal gland of bullocks injected into the veins of dogs has no effect on the blood pressure.

The same extracts fed to babies cause increase in metabolic activity, as evinced by increase in nitrogen eliminated by the urine.

The following history of a case of tumor of the pineal gland seems to show that in adult life entire destruction of the pineal gland does not affect metabolism. It is inserted here for its value as negative evidence and as an example of a very unusual type of pineal tumor.

*History of a Case of Tumor of the Pineal Gland.* The latest studies of tumor of the pineal gland show that there is a measurably definite pineal gland syndrome.

1. General symptoms of a brain tumor: Headache, vomiting, vertigo, optic neuritis.

2. Local symptoms due to pressure on the aqueduct of Sylvius with internal hydrocephalus, causing general tumor symptoms and leading to mental apathy.

3. Local symptoms due to pressure upon the corpora quadrigemina with irritative and paralytic symptoms pertaining to the eye muscles—such as lateral or vertical nystagmus, paralysis of the vertical movements of the eye, and of individual eye muscles.

4. Those due to pressure upon the anterior cerebellar peduncles with forced movements and asynergy.

5. Specific symptoms — adiposity, increased growth of the sexual organs and premature psychical and physical growth.

The symptomatology of pineal gland tumors has been gone over carefully by previous writers, including especially the latest contributions of Bailey and Jelliffe (*loc. cit.*), so that it is not necessary for us to dwell upon this matter in detail.

Mr. W. C., age forty; married; lawyer by occupation. He was first seen by me in consultation with Dr. Daniel Lewis, in April, 1905.

The family history was negative.

Previous history: The patient had always been a man of good health. He had not used alcohol or tobacco to excess, and has never had any luetic infection. He had suffered from severe headaches.

The present illness began in the fall of 1909—about seven months before I saw him.

His first symptom was dizziness, and soon after that he complained of headaches. The vertigo came on in attacks, which were quite severe; so that he would sway to one side, and would have to catch hold of something. These attacks of vertigo grew more severe and he would sometimes fall or sink down.

In addition to these attacks of vertigo with forced movements, he had attacks of sudden falling or collapsing, without any vertigo or tinnitus or loss of consciousness. These attacks lasted a few minutes and he would then get up and be perfectly clear mentally. (Cerebellar shocks.) In the attacks of falling, he generally fell forwards.

Besides these seizures, he had attacks of sudden blindness, lasting for two or three minutes. These attacks would come on sometimes when he was in the street, and he would have to grope his way. He had these blind spells sometimes every day in succession. The attacks of vertigo, following the blindness, did not occur when he was in bed or lying down.

The symptoms gradually increased and there developed later attacks of tachycardia and respiratory disturbances of somewhat Stokes-Adams type. His headaches were not very severe; they were dull, more often frontal but sometimes occipital, and were not worse at night. There was no record of any vomiting attacks.

He gradually developed some disturbances of vision. His sight failed and on examination, two days before I saw him, by Dr. Webster, a double optic neuritis with retinal hemorrhages was found.

Dr. Webster wrote that the papillæ were abruptly swollen, plus 4 to 5 diopters—the swelling gradually shading off.

There were retinal hemorrhages in both eyes, much more in the left, and this was decidedly the worse eye in all respects. His vision was slightly blurred, but no exact tests were recorded.

When I saw him, he had the appearance of a well nourished man; mentally clear and intelligence unimpaired, except that there was a little tendency toward forgetfulness of recent things.

He walked without ataxia, but swayed a little on standing with the eyes closed.

An examination of the cranial nerves showed olifaction to be unimpaired; dimness of vision, the left worse than the right, and optic neuritis, as noted above. The pupils were even and reacted to light. The ocular excursions were normal and there was no nystagmus. He had no trigeminal pain or anesthesia.

The facial movements were normal and there was no tremor of the lips. There was, however, a distinct oscillation of the tongue. Speech was almost normal, though he had difficulty in getting out some words. Deglutition was normal Taste and hearing were normal.

There was some rather coarse tremor of the hands, not increased on movement. The tremor was rather irregular and jerky and more so in the left than in the right.

The power of the arms was unimpaired, and the finger-nose test was normal, except for the influence of the jerky tremor. There was no anesthesia.

The movements of the hands were not ataxic and his writing was normal, except for a slight irregularity due to the tremor. There was nothing in the arms that showed any disturbance of co-ordination, and the case was observed before the time of diadochokinesis.

The power of the lower limbs was normal. He showed no asynergy. The knee jerks were exaggerated; the left more than the right. There was no clonus or Babinski; no anesthesia and no loss of deep sensibility.

There were no organic disorders of the thoracic or abdominal viscera.

Two and a half months later, I saw the patient again. At this time he was able to stand and walk without ataxia. His history was that since I had seen him before, he had had one very severe seizure, in which he dropped suddenly—the knees giving way, and he would have struck the floor if he had not been caught. There was a little dizziness accompanying it.

He had had another attack, which he called "a trembling fit." He got over these attacks in a short time.

He had had some frontal headaches, and had gradually lost his sense of smell; the vision in the right eye was greatly impaired—that of the left was nearly gone. He had been mentally clear and had slept well.

My examination of him showed no very new phenomena. His tremor had increased and the face was involved as well as the tongue and hands. There had been no involvement of the ocular motor nerves, nor of hearing or taste.

His speech had continued clear. He was generally somewhat weaker. The optic nerves showed more hemorrhages and papilloedema. There was no distinct paralysis of the arms or legs. The movements of the arms and hands were normal and there was no asynergy. The knee jerks were exaggerated—the left more than the right. There was no clonus and no Babinski. The urine showed a trace of albumin, but no sugar.

I did not see the patient again, but learned that he grew gradually worse and died about two months later—making the course of his disease about a year.

The autopsy was made by Dr. F. C. Wood, to whom I am indebted for the following report:

"The examination of the body of Mr. ——— showed the following lesions in the brain. When the skull was opened there was a considerable escape of fluid from beneath the meninges. The fluid was clear and light colored. The convolutions were considerably flattened showing pressure somewhere within the brain. No difference in resistance could be determined between the two hemispheres. There was no meningitis, and no thickening of the pia or dura. On opening the lateral and third ventricles the three spaces were found distended with clear fluid and very much larger than normal. Slightly posterior to the corpora quadrigemina and pressing on the pons so as to obliterate the lumen of the aqueduct of Sylvius was a small, firm, whitish tumor, measuring 3.5 by 2 cm. This was pressing on the left half of the cerebellum and on the left posterior corpus quadrigeminum. It was connected with the near-by tissue only by a small fibrous pedicle and a few vessels. The anatomical structure shows it to be a fibrosarcoma, whose exact origin is somewhat in doubt. The pineal body could not be found, so that it probably is a tumor replacing that organ. Such tumors are exceedingly rare, only a few being on record. It is also possible that this growth arose from the fold of the pia near by, though this seems less probable."

This case is put down as tumor, probable origin in the pineal gland. The patient had evidently lost his pineal gland, and in so far it represents a case in which the pineal gland had disappeared and been replaced by the fibrosarcoma. If, therefore, this gland has any important functions in adult life, some manifestations of its loss should have been present. There were, however, none of the symptoms which have been attributed to the disease of this gland, such as disturbances of growth or nutrition.

It will be seen that the tumor, wherever it started grew back, became subtenorial and pressed upon the cerebellar hemisphere, and also to some extent upon the vermis. This pressure would probably involve disturbances in the anterior peduncles of the cerebellum, and this would explain the forced movements forward, and the coarse tremor, which probably was of mid-brain origin.

The sudden attacks in which he dropped down to the earth belong to those clinical phenomena, which I class under the head of "cerebellar fits" or seizures. They are not, strictly speaking, "fits"—that is to say, there was no loss of consciousness and no motor spasm—but they were sudden, explosive disturbances of co-ordination and equilibrium, due to interference with the cerebellospinal mechanism.

The sudden attacks of blindness must have been due to the pressure upon and temporary spasm of the posterior cerebral arteries supplying the occipital lobes.

The fact that there were no oculomotor disturbances would indicate that the tumor had no important influence on the midbrain, but came, as Dr. Wood supposed, from the pineal gland, and exerted its influence by pressure upon the cerebellum directly. It did not early press upon the aqueduct of Sylvius, stopping it, as is often the case with pineal gland tumors.

There were no disturbances of trophic character in this case; no adiposity; no great emaciation; no skin changes that were noted, at least by any of us, and I take it to be pretty well established that the pineal gland, if it has any functions of this kind, exerts them during the period of growth.

### Report by Dr. William N. Berkeley.

*Anatomy of the Pineal Gland.*—Descriptions of the human pineal are accessible in all the standard text-books and need not be repeated here. We shall note only the points of difference in certain of the lower animals.

The calf's gland weighs from one-quarter to one grain in calves averaging one hundred pounds in weight. Its shape is much like that of a small cone. It is about one-quarter of an inch in longest diameter, soft and grayish white, contains no cysts as a rule and no precipitated calcium salts recognizable with the microtome-knife or in the mortar. After working with calves' glands for six weeks it was found so hard and so expensive to get them in fresh condition that all our later work was done with the glands of young bullocks (two to three years old).

The bullock's gland is much firmer than that of the calf, reddish white or grayish white and weighing (extremes) one to ten grains. So far as has been observed in many thousands of young cattle brought to New York markets the gland does not appear to contain cysts or precipitated salts. The adjacent pia and arachnoid are often black from deposition of pigment. In histology it does not differ materially from the rabbit gland described below.

In rabbits the pineal gland is somewhat longer and slenderer than in the bullock. Its anatomical *situs* and relative weight are about the same. It is covered and in a measure supported by the large vessels of the velum interpositum. Microscopical sections show solid trabeculæ of roundish cells with large nuclei. The nuclei are somewhat larger than red blood cells and stain rather faintly with hematoxylin. The connective framework is attenuated, and the blood vessels are small. Upon its surface the flattened nuclei of its ependymal covering are seen. It bears a remarkable likeness to the parathyroids of the same animal, and has no resemblance to brain-tissue. The pineal gland in rabbits and guinea-pigs cannot be removed *intra vitam* without rupturing a number of large venous sinuses under and around it, and to destroy it the cautery must be used.

*Laboratory Work with Pineal Gland.*—The plan for this work has embraced blood-pressure experiments, feeding experiments on laboratory animals, and children, excision experiments, and observation of nitrogen elimination in children while the gland is fed.

The blood-pressure experiments were virtually negative. Two dogs were used. The first dog received in rapid divided doses, intravenously, a concentrated solution of the nucleoproteid extract of 30 calves' glands. There was no response. The same animal then received intravenously two ounces of the globulin—albumin content of the same glands—without result. The second dog received a concentrated filtered saline solution of 24 bullocks' pineals, with no essential response.

In this connection should be mentioned the work of Jordan and Eyster, from which we quote the following summary:

J. A. E. Eyster (with H. E. Jordan).—An aqueous extract of the pineal gland of the sheep causes, on intravenous injection, a fall of mean arterial blood pressure in

the sheep, dog, cat, and usually in the rabbit, greater than the fall obtained from a similar extract made from other portions of the brain. The fall of blood pressure is associated with a vascular dilatation in the intestines, and since there is no important change in pulse rate, and no important effect on the excised mammalian heart the dilatation would seem to be the sole cause of the decrease in blood pressure. Acidulated aqueous extracts of the pineal body cause on intravenous injection in the rabbit a moderate and transitory diuresis. There is no very definite effect on respiration in the anesthetized animal. The results as a whole would seem to indicate a relatively small degree of activity of extracts of the pineal body so far as the organs studied are concerned.—(*American Journal of Physiology, 27,* 1910-11.)

Dixon and Halliburton (*Quarterly Journal of Experimental Physiology,* 1909) have reported as negative some blood pressure experiments on cats anesthetized with urethane. The pineal extracts were made with boiling Ringer's solution, cold Ringer's, alcohol, and one-tenth of one per cent. hydrochloric acid. There are other scattered references in the literature—mostly negative (*vide* introduction by Dr. Dana).

Blood pressure experiments were incidental to our main purpose, and were not pursued further.

*Nitrogen Elimination in Children.*—The two children selected, Margaret O'D. and Eugene R., from the children's wards of Bellevue Hospital, were placed at our disposal for the three weeks of the experiment through the courtesy of Dr. L. E. LaFétra, to whom we must express herewith our high appreciation of his kindness.

The girl was 8 years old and had been in ward B5, Bellevue Hospital, for some weeks with mild chronic arthritis (no fever). Her diet had been uniform for some time and was not changed during the experiment. Nothing was otherwise noteworthy in her case except that she had a little albumin in her urine quite constantly, generally *without* pus or casts.

She had her daily total urinary output of nitrogen determined for a week under ordinary diet and medication. Then for one week she was given pineal capsules in addition, three per day, after eating. For a third week (8 days more accurately) the pineal capsules were stopped, and a daily determination of nitrogen made again as in the first and second weeks.

Eugene R., the boy, was four years old. He was admitted with subacute purpura rheumatica. He was treated and his urine examined in the same way as above except that the 6th day's urine in the second week was lost by reason of the child being removed temporarily to another ward, and no pineal was given him *after* the sixth day of the second week. It will be noted that in the case of the girl there was a slight, and in the case of the boy, a marked, increase in the total nitrogen during the second week.

The number of cases tried out in this way will have to be increased largely to arrive at definite conclusions, but the results so far reached harmonize with the experimental and clinical data set forth elsewhere in this paper.

The two children were mentally normal and no special account was taken of their mental condition.

A little of the boy's urine was lost on several days, but not enough to vitiate the final results.

*Excision experiments* are also incomplete. It may be said here, however, that I have succeeded in exposing and destroying the pineal gland in young guinea-pigs, and that one of the animals survived the operation for two weeks in excellent health, when he died, apparently from a small abscess at one of the stitch-holes in the scalp. Excepting a failure to grow as fast as the control in the same cage, he showed no evident disability of any kind. It is not thought, however, that this observation will have any weight, unless our subsequent work (which we are planning on a larger scale along the same line) confirms it.

*Feeding Experiments.*—The laboratory animals fed were kittens, young guinea-pigs, and young rabbits. This work has extended over 18 months and has progressed far enough to produce some interesting if not convincing facts.

It is well enough known that the *growth* of an animal is a function of many variables; *how many,* we cannot even estimate. Strains of a single species vary enormously; to compare the growth of a terrier and the growth of a St. Bernard would be manifestly absurd. Quantity and kind of food, congeniality of other animals in the same cage, light, air, temperature, sex-differences, all enter into the computation, and intercurrent disease is an additional unknown quantity. Also, where the mental life is a factor (as in the case of children) the influence of the nervous system upon the bodily development is all-powerful. The feeding experiments we have undertaken are therefore set down only for what they are worth, and we shall await results in other laboratories before feeling sure just what the value of our own observations may be.

Not to dwell prolixly on details, our observations have been as follows:

1. Of eight half-grown guinea-pigs, well fed (an excess of bread and fresh cabbage, no water) in an airy and well-lighted room, under observation for five weeks, all in the same cage, four received intraperitoneal injections, three times a week, of pineal nucleoproteid, and four were kept as controls. The dose of nucleoproteid was fifteen minims of a solution of which one ounce represented 30 calves' glands. The controls gained 25 per cent. in weight; the subjects gained 36 per cent. The difference was perceptible to the eye, and the subjects could be picked out by persons not knowing which had been injected.

2. Of 12 small kittens, selected at random from tenement back-yards, six were fed on calf's pineal, and six were kept as controls.

They were all extremely unhappy in confinement, and several of the controls and one of the subjects died. But the remainder, who were finally turned into an outdoor enclosure (with shelter at night) did

very well, and the subjects outgrew the controls rapidly in activity, size, intelligence, and resistance to intercurrent disease. The best control, beginning with a weight of 11 ounces, gained 4 ounces in two months and a half. The best subject, starting with a weight of 12 ounces, gained 12 ounces more—doubled his weight. The food was milk and raw meat. The medication for the subjects was fresh gland—one calf's gland apiece per day, or thirty minims of a standardized solution of nucleoproteid in the milk.

3. Twelve baby guinea-pigs, laboratory-bred, were selected for a third experiment. Six were fed for four months on the pineal capsules described below (one three times a week) and six were kept as controls. The subjects increased their weight (average of five surviving) 325 per cent.; the controls increased their weight (average of four surviving) 250 per cent.

4. Ten small rabbits were selected for a fourth experiment. They were of varying color and size, and did not appear to be of the same parentage. They were under observation for five months. The five subjects were fed on "capsules" (see below). One died. The four survivors, weighing *in toto* at the beginning of the experiment 2975 grams, gained in the period mentioned a total of 5770 grams, or an average of 1442.5 grams per rabbit.

The five controls met with various accidents in the period of experiment, and the three survivors at the end of the time had gained in all 3223 grams, or an average gain of 1074 grams per rabbit.

The subjects were beautiful specimens—clean, fat, active, and salacious. The gain they made is certainly remarkable. One of the smaller ones trebled his weight exactly.

*Therapeutic Experiments in Human Beings.*—A search of the Index Medicus for twelve years back shows little or no authoritative allusion to any former therapeutic employment of pineal gland.

Cyril Ogle (Trans. Path. Soc., London, 1899), reporting a case of pineal tumor, mentions that "Extracts of it (pineal gland) are sold to be administered in functional disease of the brain due to failure of nutrition; in cerebral softening, chronic mania, and dementia," but he appears to discredit this use of it and to know of no real or supposed function of the gland except the two century-old supposition of Descartes. There is no information accessible to us as to how this preparation was made.

For our own work, after various unsatisfactory methods of dosage, a physiological dose was adopted; the attempt being made to estimate the actual work that one gland could do instead of its mere weight.

Twelve bullocks' pineals, perfectly fresh, are rubbed up with a suitable amount of milk sugar till extinguished. The mass thus obtained, after thorough drying, is distributed into one hundred capsules. This is the only strength of capsule we have used, and when "capsule" is spoken of in this paper, this capsule is meant. It is calculated to correspond to 150 pounds of live bullock.

The patients—all children—amounting to fifty in round numbers, have been partly in the care of Dr. Dana and myself, partly in the care of Dr. H. H. Goddard and Dr. W. S. Cornell, of the Training School at Vineland, N. J., and partly in the care of Miss Carol K. Young, instructress in one of the ungraded classes at Public School 12, corner Jackson and Henry streets, New York City. One child was in the care of Miss Jane Shaw, of the same public school, and one of the Mongols was in the ungraded class of Miss Beswick, Public School 64, Brooklyn. Two reports are from Dr. Eleanora B. Saunders, South Carolina State Hospital, Columbia. We take this opportunity of saying how deeply we feel indebted to all these gentlemen and ladies for the kind and intelligent interest with which they have furthered our work.

In reporting the cases it has been the special object of all concerned to make the reports as objective as possible, and every effort has been made to exclude bias on the part of the observers. After a more or less complete account of the cases a summary of the results will be given below. The Vineland cases have been reported with such care and thoroughness that it has been thought well to give them a section by themselves at the end of this paper.

Case I.—John C., P. S. 12 (Miss Carol K. Young). Irish-American. Height, 5 ft. 8 in.; weight in proportion. A case of gigantism. Age, 14 yrs. Date first visit, November 22, 1911. Family history: Mother, 40 yrs.; three other children, all healthy; born 9 mos. pregnancy: had rickets and marasmus in early childhood; walked at 4 yrs.; said a few words about 2 yrs.; does no mental work; going to Miss Young three years. Color of skin: Fair. Mouth and neck: Tonsils and adenoids bad. Treatment: November 25, 1911, 2 caps.; had tonsils removed Wednesday; has not wet bed since. December 5, 1911, 2 caps.; nose operation finished; feels better. January 2, 1912, has taken caps. through December; looks better; not much mental change; prescribed 3 caps. per day. February 16, 1912, no change.

Case II.—Sam F., P. S. 12 (Miss Carol K. Young). Height, 52 in.; weight in proportion. Age, 12 years. Date first visit, November 22, 1911. Family history: Mother, 39 yrs. old, healthy; two children dead; 5½ yr. boy looks normal; two other boys healthy; father healthy, 37 yrs. old, tailor. Previous personal history: This boy born Russia, at term; easy labor; indigestion and fits in early infancy; not after second year; said papa, mamma, at 15 mos.; walked at 18 mos.; he was evidently mentally backward at 2 yrs.; did not go to school till 9 yrs.; is said to do no mental work whatever. Mouth and neck: Good teeth, some need filling; special senses, and other organs negative. Treatment: 2 caps. a day. February 15, 1912, no improvement.

Case III.—Aaron G., P. S. 12 (Miss Carol K. Young). Weight, 43½ lbs. Height, 46 in. Age, 7 yrs. Date first visit, November 14, 1911. Family history: Mother healthy looking, 36 yrs. old; two children; other one, boy, 10 yrs., normal; father "ailing," 38 yrs.; one miscarriage. Previous personal history: 8½ mos. born; mother day and a half in labor; no instruments were used; "papa, mamma," at 12 mos.; walked at 18 mos.; frequently ill with diarrhea, or teething, or something else; is now very slow and quiet; does almost no mental work; habits good since infancy. Status præsens: P. 80; T. and R. good. Color of skin: Good. Mouth and neck: Mouth breathing, but not aggravated. Lungs and heart: Good. Abdomen: Negative. Treatment: Pineal gland, one a day. November 21, 1911, 2 caps. a day; tonsils and adenoids removed. December 26, 1911, 2 caps. a day; has physically improved, though attending irregularly. Height, 46½ in.; weight, 44½ lbs. February 16, 1912, has not improved mentally more than might be expected from removal of tonsils and adenoids.

Case IV.—Edward L., P. S. 12 (Miss Carol K. Young). Weight, 60½ lbs. Height, 52¾ in. Age, 10 yrs. Date first visit, November 14, 1911. Family history: Mother, 44 yrs. old; had six children; one dead at 9 yrs. of "heart-clapping"; three miscarriages; father, 55 yrs. old, tailor; now working. Previous personal history: This boy born 9 mos., 2 hrs. labor, no forceps, no doctor; said "papa, mamma" at 9 mos.; walked at 1 yr.; for first six months of life had "convulsions," not afterwards; seriously ill once with blood poisoning; mental age (Binet), 5-6 yrs; Miss Young says he can learn nothing; and has retrograded in the last three years; mild temper; no passion; very strong physically; can knock 13-yr.-old brother down; good grip. Status præsens—Color of skin: Fair; vacant expression; triangular face. Special senses: Fair. Mouth and neck: Fair; "habit" mouth breathing; organs normal. Urine: Normal. Treatment: Pineal gland, 2 caps. per day. November 21, pineal gland, 2 caps. per day. November 28,

pineal gland, 3 caps. per day. February 16, 1912, no progress.

Case V.—Israel M., P. S. 12 (Miss Carol K. Young). Weight, 50¾ lbs. Height, 46¼ in. Age, 8½ yrs. Date first visit, November 15, 1911. Family history: Mother 32 yrs. old, healthy; five children alive; two miscarriages; one died suddenly at age of 2 yrs.; brothers 14 and 10 yrs.; sister of 2 yrs. healthy; sister of 12 yrs. at Randall's Island, insane after meningitis and diphtheria. Previous personal history: This child said to have no memory. Color of skin: Good. Special senses: Has glasses but won't wear them. Mouth and neck: Negative. Treatment: One cap. of pineal per day; early to bed; liberal and regular diet. December 23, 1911, been absent a good while; promises now to come regularly; prescribed 2 caps. December 30, 1911, prescribed 2 caps.; grown ½ in.; weight, 51½ lbs. February 16, 1912, Miss Young reports that though capsules have been given regularly since January 1 there has been no mental improvement.

Case VI.—Abraham S., P. S. 12 (Miss Carol K. Young). Weight, 71 lbs. Height, 54¼ in. Age, 15 yrs. Date first visit, November 21, 1911. Family history: Mother 58 yrs. old; nine children living, one miscarriage; one dead at 4 mos.; 20 grandchildren; father about same age; said to be healthy; all children and grandchildren clever except this one. Previous personal history: This boy born 9 mos.; mother says no instruments were used; bottle-fed; diarrhea, convulsions, pneumonia when a baby; convulsions only once (scarlet fever); walked 5 or 6 yrs.; talked 7 yrs.; was "very weakly, and till a year or so ago could eat only milk and water." Status præsens: Temperature normal; pulse and respiration normal. Color of skin: Fair. Special senses: Negative. Mouth and neck: Negative; other organs negative. Treatment: 2 caps. pineal gland. Capsules were given regularly to February 16, 1912. There was no improvement.

Case VII.—Simon G., Brooklyn (Dr. Berkeley). Weight, 45½ lbs. Height, 46 in. Age, 5½ yrs. Date first visit, November 14, 1911. Family history: One other child, 11 yrs. old, normal; father healthy, 44 yrs. old; mother 35 yrs. old, healthy; no miscarriages. Previous personal history: Carried 9 mos.; midwife; mother made good recovery; spoke and walked normally up to 2 yrs. age; was perhaps precocious, then began to go back; now is unwilling to say anything except when angry or excited, and mother is not sure he understands anything; habits very bad; expression vacant. Treatment: One cap. a day. November 22, 1911, 2 caps. a day. November 29, 1911, 2 caps. December 6, 1911, 2 caps; mother thinks he is better; frequently wets himself by day; regularly at night; stools better; mother thinks he understands better. December 18, 1911, been without capsules for 3 days; now prescribed 3 per day; says a few words; picks his own variety of candy in confectioner's; will pick up things for you and hand them; seems less nervous; mother appears encouraged. January 3, 1912, 2 caps.; mother speaks cheerfully; says he buttoned up his own coat yesterday; still wets and soils himself, but "versteht etwas mehr." January 9, 1912, still wets and soils himself; mother thinks he understands more than he did. March 1, 1912, parents continue to bring the child, and report cheerfully. He is still under treatment. This boy has made undoubted mental progress.

Case VIII.—Rebecca S., P. S. 12 (Miss Carol K. Young). Weight, 52 lbs. Height, 51 in. Age, 9 yrs. Date first visit, November 22, 1911. Family history: Six children in all: the others are healthy; parents normal. Previous personal history: Does no mental work at all; always backward; wets herself frequently; cannot do an errand. Color of skin: Good; organs negative. Treatment: 2 caps. a day. January 3, 1912, been coming irregularly; not much change; prescribed 2 caps. This patient was kept on the treatment regularly till February 1, 1912. She made no improvement.

Case IX.—Hannah T., P. S. 12 (Miss Young). Girl 9½ years, weight and height about normal for age. Family history negative so far as it could be got. Child was born at term; labor precipitate; no instruments. Well until 5 mos. of age, then had "convulsions." Has had pneumonia and bronchial trouble several times. Color of skin: Fair. Wears glasses. Has been operated on four times for adenoids and tonsils. The thorax is rickety. Organs negative. Has been mentally retarded for a number of years past. Child got two caps. of pineal gland per day regularly from the 1st of January, 1912. On Feb. 26th Miss Young reported as follows: "This child has improved most of all since taking the gland. She began the first of the year, and has shown a decided improvement ever since. A year ago she could not write a word or sentence without help. Now she writes simple sentences in language without any help. In September she could not spell a word. At the end of January in a spelling review of 40 words she spelled 38 correctly. She reads much better than she did, and can now do simple combinations in number. She has always tried very hard to sew, and since January 1st has completed a sofa-cushion in cross-stitch embroidery. I am very proud of Hannah's improvement."

Case X.—Julius B., P. S. 12 (Miss Young). Oct. 28, 1912. Boy, 9 yrs. Weight, 56 lbs.; height, 50¼ in. Family history negative, except that an older brother is deaf and dumb. This child was born normally; talked and walked at the usual time; was never sick. On the date of his first visit to the Clinic Miss Young writes that he has been in the class for defectives for some time; is fair with figures, but cannot remember any English words for a day at a time. The physical examination of this boy showed nothing amiss. He was placed on pineal gland caps.—one per day for the first month; afterwards two. On Nov. 18 he had gained half an inch in height, 1½ lbs. in weight, and had improved in appearance; his teacher also sent word that he was improving faster than before in his class-work. On Feb. 26, 1912, Miss Young wrote as follows: "J. has improved somewhat. He now completes his work, which he rarely ever did before. I have seen a marked improvement the last month, though he has taken the gland since the last of October. He has always done fairly good work in numbers, but has been poor in reading, spelling, and language. He could hardly write a complete sentence in language work without help. But he has surprised me lately. He can now spell a few words, too, without help, and his writing has improved very much. He has always been slow and lazy about his manual work, but has completed more work at bench and seat in the past two weeks than in any two months previous. He is now taking a double twist of raffia in weaving a basket, and is making a book-rack at the work-bench. I feel certain this new interest is due to pineal gland."

Case XI.—Rebecca R., P. S. 12 (Miss Carol K. Young.) Age: 12 yrs. Height and weight: Good. Date first visit: Nov. 22, 1911. Family history: Mother 44 yrs. old; bronchitis and asthma; two children died in infancy; two miscarriages; one married daughter, 25 yrs old; healthy; two grandchildren; this child born 9 months; 4 hours' confinement; midwife; up in 7 days; child had a "headache" for 9 months after her 4th yr. and afterwards was mentally backward and had an impediment in her speech. Tried hard at school but was very backward. Status præsens. P: 80, good. R.: Good. T.: Normal. Color of skin: Excellent. Special senses: Good ears. Mouth and neck: Defective articulation; occluded nose; referred to nose and throat department. Treatment: Pineal gland, 2 caps. per day. Dec. 20, 2 caps. Dr. Broder reports (per mother) nose now open. Dec. 27th, 2 caps. Miss Young says she makes no mental progress at all though evidently growing larger and stouter. Weight today, 99 lbs. Jan. 3, prescribed 2 caps. No evident change. Miss Young writes Feb. 26, 1911: "This girl has improved much the past 6 weeks. Has been taking the gland since November, though I fear not regularly until I began giving it. She spells better; writing is neater, and she reads quite well in first reader. Seems to want to work at her lessons and before only wanted to sew or embroider. Her number work is not so well done but is better. Seems to enjoy doing things as never before. Will begin work as soon as she enters the room."

Case XII.—Reuben V., P. S. 12 (Miss Carol K. Young). Weight, 50½ lbs. Height, 50¼ in. Age, 9 yrs. Date first visit, July 22, 1911. Family history: Father reported healthy; mother, 46 yrs. old, healthy; five other older children, two boys, three girls; one boy married, two healthy children; mother's appearance suggests old specific disease. Previous personal history: This child born 2 hrs. labor; 9 months gestation; from 6 months to 6 yrs. had "Krämpfe," which have now for 3 yrs. ceased; did not fall, not bite tongue, nor lose consciousness; seemed only to have "Schreck"; walked at 3 yrs.; said "Mamma," "Papa" at 4 yrs.; now talks freely, but only mother can understand him, as articulation is bad; has formerly been to Defectives' School, but "cried and ran home"; has dull expression, widespread and flattish ears; prominent jaw, four whorls on scalp, very short little fingers; two years ago was in Randall's Island for 10 weeks, then taken home by parents. Status præsens: P., good; R., good; T., slightly raised by tooth infection; Color of skin: Very good. Special senses: Appear good. Mouth and neck: Bad teeth, tonsils and adenoids. Lungs and heart: Good. Abdomen: Negative. Slightly constipated; good appetite. Urine: Negative. Treatment:

Gargle; pineal gland, once a day. August 14, glasses have been provided for myopia; cross-eye not relieved; tonsils and adenoids removed by Dr. Broder; weight now 50¾ lbs.; height, 51 in.; sleeps better; mother thinks mental condition slightly improved; prescribed pineal gland once a day. August 21, 1911, mother is pleased, and says boy continues to improve; teeth still vexing him. August 28, 1911, Weight, 52½ lbs.; height, 51 in. September 30, 1911, weight, 52½ lbs.; height, 51 in., same as last time; now going to school; teeth, eyes and adenoids in order; teacher says child is very dull, and she cannot understand any words that he says, but he is pleased with school, likes to go, and she hopes for improvement; does not know the way to school. October 14, 1911, weight, 54¼ lbs.; teacher writes encouraging letter, and boy is evidently improving; he goes now alone to school without mishap. October 21, 1911, same; Binet tests show 3 yrs. development; great indistinctness of speech makes it almost impossible to recognize his words; *pencil* is "sheeli"; *box* is "ox," and finally by repeating the correct sound loudly to him "*box*." October 28, 1911, weight, 53 lbs.; height, 51½ in.; understood much that he said—first time to-day. November 18, 1911, weight, 54 lbs.; height, 51¾ in.; wets himself still at times, but has a much more intelligent expression. November 27, 1911, prescribed caps., 2 a day; sang me a little song and drew a man for me. December 9, 1911, prescribed caps., 2 a day; weight, 56 lbs.; height, same; still wets himself. December 23, 1911, prescribed 2 caps. December 30, 1911, prescribed 2 caps; teacher says he learns little, but plays with spirit and intelligence; and his mother says his understanding of household matters is very good; prescribed tincture belladonna for the wetting of bed. Miss Young writes, February 26, 1912: "Reuben has been taking gland since July; has been in school for 6 mos.; understands everything I say now, though at first he would stare at me if I spoke to him. If things are to be done about the room, he does them without being asked. Recognizes red and can say it. Can select all colors; calls me by name and can call some of the other children, but not all; shows much intelligence in games of 'drop handkerchief,' 'eat mouse,' etc.; can catch ball and enjoys games; tries to imitate other children; can put on and button his own coat now; goes home from school alone. Does not wet himself; asks me for permission to leave the room when necessary." Both doctor and teacher have been greatly interested in this child, and his improvement has been gratifying.

Case XIII.—Meyer K., P. S. 12 (Miss Carol K. Young). Weight, 49½ lbs. Height, 47 in. Age, 6½ yrs. Date of first visit, October 17, 1911. Family history: Mother, 31 yrs. old, says she is "schwach," but looks healthy; father, 31 yrs., healthy, bricklayer; couple came singly to this country, 11 and 10 yrs. ago; married 10 yrs. ago; ages of four children, 9 yrs. boy; this one; 5 yrs. boy; 2 yrs. girl; all other children well; no miscarriages. Previous personal history: This child delivered after 3 days' labor; no instruments, but born asphyxiated and remained "todt" for 4 hrs.; then cried for 24 hrs; breast fed; "Papa," "Mamma" at 12 mos.; walked at 13 mos., but often fell down; never had fits; child is reported by his teacher to be "very slow," but to have "improved very much since she took him last year" (Miss C. K. Young); holds pen with "intention tremulous" fingers; can make letters; knee jerks exaggerated; ankle clonus very slight; no difficulty with stools and urine; prognathous jaw, thick lips. Binet tests, 5 years. Status præsens: P., good; T. and R., normal. Color of skin: Very good. Special senses: Negative. Mouth and neck: Operated twice for tonsils and adenoids; slight "habit" mouth breathing persists; recommended plaster for mouth at night. Abdomen: Negative. Treatment: Pineal capsules, 1 a day. November 11, height, 47¼ in. November 18, weight, 51½ lbs.; height, same; looks well. November 28, weight and height, same; prescribed 2 caps. December 16, teacher said to approve of his mental progress; height, same; weight, 52 lbs.; prescribed 2 caps. December 23, 2 caps.; looks well; December 30, 2 caps.; looks well; grown ½ in.; weight, 52 lbs.; teacher reports favorably. Miss Young reports, February 26, 1912: "Great improvement in 5 months. Can now compose and write five or more sentences in language. Writing improved very much; knows all letters; in a spelling review of 40 words for the month of January he spelled 32 words correctly. Is more careful about number work; can multiply with one number; knows tables to 11; can add and subtract; can read better, but this shows least improvement; manual work is better; has much better control; is now doing a basket of reed and raffia and is making a book rack of wood at work bench."

Case XIV.—Rose R., P. S. 12 (Miss Carol K. Young). Weight, 60½ lbs.; height, 31½ in.; age, 9 yrs. Date first visit, November 11, 1911. Family history: Mother, 43 yrs. old; one miscarriage (2 mos.) 6 yrs. ago; 5 boys, 16, 15, 12, 5, 22 mos.; all healthy mentally. Previous personal history: 9 mos. child; mother in labor 16 hrs; no forceps; walked 14 mos.; talked at 15 mos.; first went to school at 6 yrs.; meningitis at 17 mos.; in bed 10 wks.; convulsions then; not since; been in class for defectives at P. S. 12 for 3 yrs; making very slow progress. Status praesens: P., 80; R., good; T., normal. Color of skin: Healthy; rosy and robust appearance; bright expression. Special senses: Eyes now fitted with glasses; seems to have good vision. Treatment: Pineal capsules, 2 per day. December 30, has been away several weeks; grown ½ in.; prescribed 2 caps.; Miss Young reports favorable progress. Again Miss Young writes, February 26, 1912: "Began treatment in November. On account of illness in family did not go regularly. Her improvement has been notable since she began taking the gland. Before her lessons seemed to be a burden to her and now she seems to enjoy them. Does not fatigue so easily. She has always been very nervous and could not concentrate for any length of time. She does not get these nervous spells as often as she did, and sticks to her work until finished. She spells well—for her—recognizes words much better and reads much better than she did. There has also been improvement in number work. She knows her tables fairly well and can add, subtract, and multiply by one figure. She has made two sofa cushions and two aprons in school since taking the gland, and that is a great deal for her to accomplish as she is so slow. She is now monitor for the lunch table, and tries to do it *well*. Six months ago I wouldn't have thought she could ever be as good as she is. Am sure her improvement is due to pineal gland. I hope to return her to the grades in June."

Case XV.—Max L., P. S. 12 (Miss Carol K. Young). Weight, 68 lbs. Height, 55½ in. Age, 11 yrs. Date first visit, November 22, 1911. Family history: Father 50 yrs. old, normal looking; mother 43 yrs. old, healthy; five children, 13 yrs., girl; this child; others 9, 7, 7 yrs.; all others healthy (7, 7 yrs. are twins, girls). Previous personal history: Mother pregnant 9 mos.; easy labor; up in three days; child walked and talked at 18 mos.; about 2 yrs. had measles; was never mentally right afterwards; had no convulsions. Status praesens: P., 85; R., good; T., normal. Color of skin: Excellent. Special senses: Nearsighted; ears, watch 2 ft.; excellent grip. Mouth and neck: Adenoids and tonsils, to be removed next week. Lungs and heart: Negative. Abdomen: Negative. Urine: Negative; abundant; good color. Albumin: None. Treatment: 2 caps. per day. Miss Young writes, February 16, 1912 "Max has been taking pineal gland nearly five months, and has improved greatly. He seemed a most hopeless case in September. Could do almost nothing except select colors. He was very inattentive, and seemed hard of hearing. Now he understands much more quickly than before. It was impossible for me to get him to do any kind of hand work, but since taking the gland he has finished weaving a large scrap basket, and has done it beautifully and with no help, except at the start. He now matches words in the story of 'Jack and Jill,' and recognizes them. Can write some letters, which he never could before. Can cut to a line and paste designs. Recognizes numbers to 10; is more helpful about room and uses better judgment in the room and on playground."

It must be noted about this case that the boy was entered in Miss Young's class only in September last. His previous educational history is unknown. Miss Young's impression, however, is that his progress has been phenomenal.

Case XVI.—Max R., P. S. 12 (Miss Jane F. Shaw). Weight, 102 lbs. Height, 5 ft. Age, 12 yrs. Date of first visit to clinic, November 21, 1911. Family history: Mother 40 yrs. old, healthy; 5 children; this boy one of twins; other twin born dead; no miscarriages; father 42 yrs. old, healthy. Personal history: Baby born without forceps, breast-fed; said "papa, mamma" at 2 yrs.; walked at 2½ or 3 yrs.; habits good from early infancy; no convulsions; Miss Shaw wrote under this date: "The lad is very restless and nervous. He has little or no self-control. In English he does the work of a boy of 10; in arithmetic the work of a boy of 8 or 9. He can do very little hand work." Physical examination entirely negative. This boy received capsules and took them with fair regularity till the middle of January. During this time his attention improved remarkably and it was noticed that he was able to sit quietly at his desk, a thing he could never do before. In his mental work he improved so much that he was placed in the regular fourth grade, and on February 1 was reported

to be doing very well. After February 1 he got no more capsules, and on February 26 Miss Shaw wrote: "Max had a peculiar habit of holding his hand before his mouth and nose, in a way that looked as if he were trying to get more air to breathe. He did this constantly before he commenced the treatment. During the time of treatment the habit disappeared. He has started to do the same thing again, and is more restless since discontinuing the medicine."

Case XVII.—Aaron S., P. S. 64, Brooklyn (Miss Phebe Beswick). This child is a Mongol. Weight, 54½ lbs. Height, 44 in. Age, 6 yrs. Family history entirely negative. Father and mother are robust, and there are four other children, all of whom are normal. Personal history: Child born normally; walked at 2 yrs.; never began to talk till taken to school for defectives last March; now says a few words, which are hardly audible or intelligible; physical condition good, facies characteristic; organs negative. His nose was operated upon for bad breathing, and he was placed on the pineal gland treatment at once. The mother has returned regularly for the medicine, and thinks the child is improving in mentality, but the time of treatment has been too short to draw permanent conclusions as yet. On February 14 Miss Beswick wrote: "In regard to Aaron S., I feel there is some improvement. His instinct of initiation seems to be more definite than before he came under your treatment. He sits more quietly at school, and does not babble at random as much as he did. As yet he does nothing at school but indulge in free play. He puts pegs in peg-board, builds with blocks, and catches the bean-bag." On his physician the child makes a much more favorable impression than two months ago.

Case XVIII.—L. W., New York (Dr. Berkeley). Girl, 7 yrs. old. Weight and height normal for age. Family history negative. This child fifth of six children; all the others said to be unusually bright. The patient is a high-grade Mongol. Skin fair and rosy. Facies perfectly characteristic. Lungs, heart, abdomen, and urine negative. Mental age (Binet tests), 4 yrs. She was put upon pineal gland on August 5, 1911. She was seen again on December 14, at which time she had grown in height and weight, and had made good mental progress. She has been kept on the treatment by her parents, and has been reported once since as continuing to improve, though no precise objective details of her mental progress were furnished. (In reporting this case it is distinctly remembered that the parents of any weak-minded child, especially of a Mongol, are apt to be very bad judges of the child's progress. It is, however, in Dr. Berkeley's opinion, quite certain from objective signs, that the progress of this child after beginning pineal gland was remarkably rapid.)

Case XIX.—E. B., S. Carolina (Dr. E. B. Saunders). Girl, white, nearly 5 yrs. old. Admitted to the S. C. State Hospital as a "defective" by an officer of the law. Family history and previous personal history very incomplete. Repeated physical examination showed nothing abnormal. She was small, anemic, untidy, irritable, cried much, dribbled saliva; was not easily distracted from anything she had her mind on; did not notice dolls, toys, etc. She ate only fairly well and was restless at night. Began pineal gland caps. furnished by Dr. Berkeley, giving three per day for fully a month, after which on account of the scarcity of the medicine the dose was reduced to two and finally to one caps. per day. Now the child is more tidy, plays and eats well, understands everything said to her and is not so peevish. There is a marked change for the better in the tonicity of the muscular tissue. She looks healthy, and has shown no ill effects from the medication; no increase of the pulse-rate, no increase of the blood-pressure; no crying. Strikingly suggestive of the effect of the pineal gland is the fact that after she had been under treatment for several months the supply of gland became exhausted, and this treatment had to be suspended. While the pineal gland was omitted we noticed that the patient cried more frequently, was a little more irritable, and had a tendency to be more wakeful at night. At present when back on two capsules a day, she is very comfortable. This patient is still under observation.

Case XX.—J. F., South Carolina (Dr. E. B. Saunders). Small girl, exact age doubtful. Admitted to the Hospital for protection. Family history bad. Previous personal history not ascertained. Physical examination of this girl showed nothing of importance except anemia and emaciation, but her mental status was bad. She had a great tendency to untidiness and a high nervous irritability. While unusually active, she was sullen when opposed, restless, inattentive and a masturbator. She cried aloud at times during the day, and was restless at night. She was a mouth-breather and dribbled saliva. She was started upon the capsules of pineal gland, one three times a day. For three weeks there was no improvement, but it was then noticed for the first time that the little girl would listen when spoken to, and that she was pleased to play with her dolls. She soon began to show jealous resentment when her nurse showed a preference for another child, or fondled the doll instead of herself. At present she still has the tendency to run aimlessly about the ward and chatter to herself, but she is much more tidy, does not masturbate, eats in an orderly manner, and sleeps well at night. She is still under observation.

Case XXI.—Benny W., New York (Dr. Berkeley).—Weight, 42½ lbs.; height, 43½ ins.; age 7 yrs. Family history: Father not seen, but reported healthy; age not ascertained. Mother, 33 yrs. old, of excellent appearance. There are three other children, all boys, aged 13, 11 and 5 yrs. respectively; all these were seen, and all were normal, or even precocious. Date of first visit: June 15, 1911. Personal history: Child born without incident, but was always backward. Did not walk till three, and has never said any connected or intelligent words. He can repeat short sentences after his mother, but this appears to be true echolalia, as he gives little appearance of understanding what he repeats. Cannot buy a pennyworth of candy. Is said to wet himself habitually, and soils himself several times a week. Mother professed herself in despair about the child and willing to do anything for his relief. Physical examination entirely negative, except that the boy is cross-eyed (1.50 D. hyperopic astigmatism). He has no physical stigmata, but presents a vacant animal face, smiles inanely and drools continually. His muscles and skin are relaxed, and he stands with bent knees and bowed head. He is said to be very "nervous," and cries a good deal, which might be attributed to the quantity of coffee he has been allowed to have. The treatment of this case consisted solely in the giving of pineal gland. His eyes were fitted with glasses, but these he soon refused to wear, and the treatment was continued without them. June 26.—Weight 43¼ lbs. Looks brighter. Mother thinks his mental condition much improved. Has gone to toilet alone and not soiled himself at all this week. Has said some connected words; cried because younger brother was dressed before him (had never noticed this before). July 3.—Mentality still improving; talks a great deal more. Weight, 41¾ lbs—a decline due possibly to the hot weather. July 10.—Weight, 42 lbs; intelligence rapidly increasing; yesterday asked his mother for the key to the toilet; has entirely ceased to soil or wet himself. Height unchanged. Nurse and assistant at the Clinic remarked upon the patient's improved appearance. Aug. 14.—Weight, 44¼ lbs.; height 44½ ins. Understands and answers simple questions, and has acquired between fifty and one hundred words. Facial expression transformed. Habits entirely correct. This patient continued to improve till late August, when the family moved suddenly to a western city and were lost sight of.

From the total of about fifty cases it seems quite possible to draw the conclusion that in certain cases of retarded development in children pineal gland may be a remedy of value. It is certainly worthy of a much more extended trial, particularly when we read the recent reports (New York Society for the Prevention of Cruelty to Children) that there are at the present time in New York City alone 7,000 distinctly feeble-minded children, or about one per cent of the school population.

Just how the gland produces so notable a mental improvement is a matter of conjecture. By reason of the minute amount of it in the normal animal constitution the only reasonable working hypothesis would seem to be that the secretion of the gland acts as a ferment, or katalyte, facilitating the exchange of nutrient material in the cells of the brain. But this is confessedly only a hypothesis.

It must be noted further, that in cases of total idiocy and gross physical defect we have found the gland useless, and that in proportion as the patient is less characterized by physical stigmata, so much more benefit does he seem to reap from pineal medication.

Whether there be any specific mental defect of childhood which may be called *apinealism* or *hypopinealism* remains for the future to decide. I am

of the opinion that the case above described of Benny W. is a true case of hypopinealism. There is, however, no question that the gland is of benefit in many cases of simple retardation, and even in such specific diseases as Mongolism we have found it of distinct value in the cases reported.

In the case of the Vineland children (see below) it must be further observed that the *physical advance* was more marked in the control cases than in the subjects—while the subjects advanced considerably more rapidly than the controls in mental accomplishment. Till the gland has been administered continuously for a much longer period than four months we shall not be able to explain this finding definitely; but it seems quite natural to suppose that given the existence in each subject of only a certain *quantum* of energy, the more this is deflected to mental lines of development, the less will be left for physical growth.

### Report by Drs. Walter S. Cornell and Henry H. Goddard, of Vineland, N. J.

The following described experiments on the use of pineal extract were made at the Training School at Vineland, N. J. This institution has 400 inmates of both sexes and of all ages (five to sixty) and of all grades of intelligence (from the low grade idiot to the high grade moron, or almost normal).

The management of the institution considers that the greatest contribution that it can make to society is from the study of the condition of these children and by examining them in all legitimate ways with various methods of treatment.

It has maintained for five years a Department of Research, where different studies and investigations have been carried on, some of them leading to valuable results. The department is not only interested in the problems that it can work out itself, but welcomes gladly any help or suggestions from those outside of the institution and is very glad to collect data or carry on work under the direction of any competent person who has a problem to solve.

In August, 1911, a visit was received at the suggestion of Dr. C. L. Dana of Cornell University from Dr. William N. Berkeley, who came as the result of the experiments that he and Dr. Dana had been making on the use of the pineal gland extract. As the result of their studies, they were desirous of trying this gland upon a group of mentally defective children. The plan was quickly approved by the Training School and Dr. Berkeley at once proceeded to pick out a group of children. Twenty-five were finally selected, being chosen, as far as possible, from among the younger children, some of each sex, and of different grades of intelligence, from the lowest to the highest grade. We next recorded the following facts about each one of these children: Mental age; the condition of the family, that is to say, whether there was hereditary feeble-mindedness or not; height, standing and sitting; weight; grip with each hand, and lung capacity.

August 24th, 1911, the experiment began by the administration per mouth of one capsule per day of pineal gland as prepared by Dr. Berkeley.

At the same time that we selected this group we selected a control group, pairing each child that was to have the glandular extract with one of as nearly as possible the same age, physical and mental, the same hereditary history and approximately the same development. These children have been measured and tested every time with the others. While, of course, no children are exactly alike in heredity or in temperament or physical or mental condition, yet, taken as groups, the one served as control for the other.

In two months each group was again measured and tested. The result of that measurement was a very slight advantage in favor of those who had taken the pineal gland. This was shown in mental capacity and in physical development except in weight, which was, on the contrary, slightly reduced. While the improvement was not great and indeed not great enough to be of itself very significant, it was nevertheless felt that it was sufficient to continue the experiment.

The gland was consequently administered for another two months. At the end of four months, the results were as shown in the table on page 846.

The groups had been reduced in the meantime by the dropping out of four children: two were so low grade that they could not be conveniently made to take the medicine, and two left the institution. Substitutes were found for two of these. Twenty-one subjects continued through the four months' trial. Of these, seven made no change; fourteen showed a gain. Of these fourteen the average gain in mentality by the Binet tests during the four months was .65 of a year, or twice normal development. The gain of the entire control group by the Binet test was only a trifle over .25 of a year. Of the controls, only nine made any gain. The average mental gain of these was .41 of a year.

It seems certain that, although slight, there is nevertheless a distinct advantage to those who have received the extract. In several cases the controls either suffered from illness or went home for a visit, so that at the end only fourteen controls were available.

It will be seen that the greatest gain has been in groups I, VII, XII, XIV, XVII, XX and XXII, where the gain has been from .8 to 1.8 years.

The children in the idiot group (mentality of from 1 to 2 years) show no improvement whatever.

When we turn to the physical side, the data are quite different. The gain in standing height for the 21 subjects averages 18.52 mm., while for the 24 controls it was 24 mm. In sitting height, the 21 subjects gained an average of 15.26 mm., while the 14 controls gained 15.28 mm.

In weight the 21 subjects gained an average of 2.06 kg. and the 14 controls gained 2.89 kg. There was no case of an actual loss of weight in either subject or control.

In the grip of the right hand the 21 subjects gained an average of .9 of a kilogram as a group, and the 12 who gained averaged 1.58 kg. The 14 controls gained an average of 3.43 kg., the 10 who gained averaging 4.3 kg. In the grip of the left hand the 21 subjects gained an average of 1.02 kg. as a group, the 17 who gained averaging 1.28 kg. The 14 controls all gained, the average being 3.75 kg.

In lung capacity the 21 subjects gained an average of 109 c. cm., the 17 who gained averaging 134 c. cm. The 14 controls gained an average of 217.8 c. cm., the 9 who gained averaging 338.8 c. cm.

The result from the physical side would seem to be conflicting with the other.* The grip and lung capacity are good measures of mental capacity in feeble-minded children, and consequently this gain of the controls is somewhat of a contradiction.

*Dr. Berkeley's explanation of this apparent contradiction is given elsewhere.

On the whole, one cannot but feel that there is a distinct influence in the extract toward mental improvement. However, all such experiments are subject to so many disturbing factors that it seems necessary, in view of the slight gain recorded, that the experiment should be continued for a longer time.

### Summary.

*Mentally.*—We find as a group the 21 subjects have gained 2.23 points. Of the 14 who gained, the average mental gain is 3.35 points. The 14 controls gained as a group 1.35 points mentally. Of the 9 who gained, the average mental gain is 2.11 points.

The subject in Groups I, VII, XII, XIV, XVII, XX, XXII, gained from 4 to 9 points mentally. In each group where there is any mental advance the children have the mentality of three years or more. Those in the idiot group (1-2) have not improved mentally.

*Physically.*—The gain in the standing height for the 21 subjects averages 18.52 mm,; for the 14 controls, 24 c.c.

In weight the 21 subjects gained an average of 2.06 kg., the 14 controls, 2.89 kg. There was no loss of weight in either subjects or controls.

In grip of R. H., the 21 subjects gained an average of .9 kg. as a group and the 12 who gained averaged 1.58 kg. each. The 14 controls gained an average of 3.43 kg., the 10 who gained averaged 4.8 kg. each.

## SALVARSAN IN CRYPTOGENETIC PERNICIOUS ANEMIA.*

By CHARLES EDWARD NAMMACK, M.D., LL.D.,

VISITING PHYSICIAN TO BELLEVUE AND TO ST. VINCENT'S HOSPITALS; PROFESSOR OF CLINICAL MEDICINE, CORNELL UNIVERSITY MEDICAL COLLEGE AT NEW YORK.

Despite the amount of careful investigation into the etiology of pernicious anemia, it must yet be regarded as cryptogenetic. Some cases will respond, temporarily at least, to treatment based upon one causative theory of the disease, while others, apparently resulting from identical etiological factors, will march rapidly on to a fatal issue. When the disease occurs in patients whose circumstances and surroundings are poor, the chances of temporary improvement seem to be much greater than when it arises in a patient whose environment is luxurious. Our hospital patients in Bellevue and St. Vincent's have responded more promptly to good feeding, with arsenic and hydrochloric acid as medicines, than have the cases seen in private practice in the homes of the well-to-do. Grawitz assigns the chief rôle in causation to the absence of great diminution in the amount of gastric hydrochloric acid. This leads to the development of an intestinal intoxication—by the absence of disinfection of food stuffs in the stomach and the failure of destruction of organisms derived from the mouth. These organisms then pass into the intestine and lead to an inflammation with the production of hemolytic toxins. Secondly, Grawitz believes that there is an incomplete destruction and metabolism of heterogeneous albumins. Based upon these ideas, he advocates a diet from which all animal albumin is excluded, carbohydrates and fats with lemon and fruit juices constituting the exclusive diet. This diet is supplemented by daily lavage with sodium chloride solution, one or two per cent., and daily colon irrigation of the same solution. He administers arsenic hypodermatically, using a neutral one per cent. solution of sodium arsenate, and warning against the use of the organic salts of arsenic.[1] On the other hand, S. P. Beebe and others have reported studies which, in their opinion, demonstrate that nitrogenous metabolism in pernicious anemia is nearly normal.[2] And A. C. Croftan advises abundant protein feeding followed by large doses of hydrochloric acid as producing results in treatment not otherwise obtainable by any means so far described.[3] The consensus of opinion at the last meeting of the American Gastro-Enterological Association seemed to be that the underlying basis of pernicious anemia was some toxin generated in the gastrointestinal tract, as a result of deficiency of hydrochloric acid in the stomach. The fact that it does not always develop in connection with cases of achlorhydria is explained by McCaskey on the supposition that an embryological fault or tendency exists only in cer-

* Discussion at Meeting of Bellevue Hospital Alumni, February 5th, 1913.

tain individuals.[4] Cabot, however, is of the opinion that neither atrophy of the gastric tubules nor gastrointestinal sepsis can be considered as the cause of pernicious anemia, as the first lesion is very possibly due to post-mortem changes, is not found in a considerable number of cases, and even when found is probably a result rather than a cause of the disease which we are studying. He also dismisses the theory of Hunter, now so prevalent, that its cause is sepsis, oral, gastric, or intestinal.[5]

The only light thrown by post-mortem study on the causation of this baffling disease is that a powerful poison has acted upon (1) the blood, producing hemolysis; (2) the spinal cord, causing systemic or patchy degeneration; and (3) the cells of the heart, liver, and kidneys, ending in fatty metamorphosis. With the enthusiasm rightly or wrongly engendered by the discovery of salvarsan, many recent cases of pernicious anemia have been injected or infused with that arsenical compound, especially when a history of previous syphilis can be extracted from a patient. Friedlander reports one case of striking benefit, the red blood count rapidly rising from 887,000 to 3,200,000.[6] Byrom Bramwell has also reported two cases with good results.[7] But in autopsy work at Bellevue Hospital, Norris has found fatty degeneration of the parenchymatous organs, especially of the kidneys, in patients dead from other diseases than pernicious anemia, who had recently undergone the salvarsan treatment. This should make us reluctant to advise its use in a disease which has a tendency in itself to produce fatty degeneration of the viscera. My experience agrees with that of Leede[8], that however useful salvarsan may be in the secondary anemia which occurs in an early stage of syphilis, its use is positively contraindicated in pernicious anemia in a man in the fifth decade who confesses to luetic infection in early life. E. F. Maynard has lately put a case of failure to benefit by salvarsan on record, in order to dispel the growing view that this drug might be a specific in pernicious anemia.[9]

## THE DISSOLVED ALBUMIN TEST FOR GASTRIC CANCER.

By F. W. ROLPH, M. D.,

Toronto, Ontario.

Assistant in Chemical Pathology, Toronto University.

The large number of laboratory methods which in the last few years have been advanced as aids in the diagnosis of gastric cancer have, for the most part, been too complicated and too unreliable to render their clinical use popular. In this general unpopularity there is one test which has suffered undeserved neglect, that is the dissolved albumin test of Wolff and Junghans. I was much impressed with the value of this reaction as carried out in Ewald's Augusta Hospital Clinic in Berlin, and further experience, though as yet rather limited, has borne out this opinion.

The function of the stomach is to prepare soluble albumin, and it is the combined action of the hydrochloric acid and pepsin which performs this service. When one or both of them are absent we would consequently expect to find no soluble albumin in the material withdrawn one hour after a simple Ewald test breakfast. This expectation appears to be realized in the cases of simple achylia, but where we have cancer of the stomach with absence of free hydrochloric acid we obtain almost as much soluble albumin as we do in the normal stomach. To account for this the originators of the test advance three reasons: (1) The presence of ferments in the cancer itself, similar to the peptid ferment of Neubauer and Fischer; (2) Albumin secreted from the growth; and (3) The diminished absorption on account of the secondary gastritis.

The method of performing the test is very simple. One hour after a Ewald test breakfast the contents of the stomach are withdrawn, tested with congo red, and filtered. *If there is no reaction with congo red* we take six clean test tubes and with a finely divided 1-c.c. pipette measure off into the first tube 1 c.c. of the filtered contents; in the second we place 0.5 c.c.; in the third 0.25 c.c.; in the fourth 0.1 c.c.; in the fifth 0.05 c.c., and in the last likewise 0.05 c.c. The next step is to make up the contents of each tube to 1 c.c. by adding distilled water; so to the first we add nothing, to the second 0.5 c.c., to the third 0.75 c.c., to the fourth 0.9 c.c., and to each of the last two 0.95 c.c.

Now to each tube except the sixth we add 9 c.c. of distilled water, to the sixth we add 19 c.c. The dilutions in the several tubes in order are now 1 in 10, 1 in 20, 1 in 40, 1 in 100, 1 in 200, 1 in 400. After thoroughly mixing the contents of each tube we remove 10 c.c. from the last one in order to equalize the amount in each.

Upon the contents of each tube is layered very carefully and slowly 1 c.c. of the following solution: Phosphotungstic acid, 0.3; concent. hydrochloric acid, 1.0; alcohol (96 per cent.), 20.0; distilled water, to 200.0.

Examine each tube at once for a white ring at the junction of the two liquids; if present in none or in the first three only, the case is benign; if present up to and including the fourth the diagnosis is doubtful but probably cancer; if in either of the last two tubes we almost surely have to do with a malignant growth.

The cases which have been published, almost without exception, show favorable reports, and I wish to add to them a few of my own.

*Cases Which Gave a Negative Reaction.*—(1) Pernicious anemia, negative in all dilutions; (2) Secondary anemia (noncancerous), negative in all dilutions; (3) Cancer of head of pancreas (operation), positive to 1 in 40; (4) Chronic gastritis, positive to 1 in 40; (5) Visceroptosis (young women), positive to 1 in 40; (6) Visceroptosis (young woman), negative in all dilutions; (7) Diagnosis uncertain, but malignancy excluded, positive 1 in 20; (8) Chronic gastritis, positive 1 in 20.

*Cases which Gave a Positive Reaction.*—(1), (2), and (3), Gastric cancer (advanced case, palpable tumor), positive to 1 in 400; (4) Pyloric obstruction, malignant (operation), positive 1 in 200; (5) Cancer of colon, with involvement of stomach (operation), positive to 1 in 400; (6) Cancer of stomach (no tumor), positive 1 in 400; (7) Cancer of stomach (advanced case), positive 1 in 400.

There are several important precautions which

must be observed in performing the test. (1) For a positive reaction the ring must form within a few minutes; a ring which only appears after standing for some time cannot be included. (2) I have found that a solution of blood up to one in three thousand will give a faint ring, so that contents which contain more than a faint trace of blood must be used with caution. (3) One must be careful with contents which contain no free acid, but a high proportion of combined acid; peptone is usually present in these cases. (4) Cancer of the cardia is not as likely to give a positive reaction as cancer in other parts of the stomach.

The test may be criticised because of its impracticability for diagnosing very early cases of cancer, but we must differentiate between the ideal and the real diagnosis of this disease, and so excellent an aid in distinguishing between a benign and a malignant achylia will often be found very helpful.

## CYSTIC POLYPUS IN THE NASAL PHARYNX OF A CHILD.

By EDWIN A. GRIFFIN, M.D.,

BROOKLYN, N. Y.

LARYNGOLOGIST AND RHINOLOGIST AT THE LONG ISLAND COLLEGE HOSPITAL DISPENSARY; LARYNGOLOGIST, RHINOLOGIST, AND OTOLOGIST AT THE BROOKLYN CITY AND NEW UTRECHT DISPENSARIES AND SAMARITAN HOSPITAL.

A lad, seven years of age, American nativity, was brought by his mother to the New Utrecht Dispensary to have his adenoids and tonsils removed. The mother said she had him operated upon for the same condition at a New York dispensary one year previous but no benefit resulted. The patient was a typical mouth breather, with a dull facial expression and a prominent nasal twang. No preliminary examination could be made of his throat or nose as he was greatly frightened by reason of his former dispensary experience. Anesthesia was induced and preparations made for the extirpation of tonsils and adenoids.

The stumps of the tonsils, which were left in after the other operation, were removed. I then inserted my finger behind the soft palate, ready to employ the adenoid curette, when a large fluctuating mass in the nasal pharynx was felt. As the patient was on the verge of coming out of the anesthetic, I quickly, by digital manipulations, delivered *en masse* a large cystic polypus with a long fibrous pedicle.

The growth, as shown in the accompanying photograph, was as large as a good sized hickory nut. Upon the second visit of the patient, I had no difficulty in making a thorough anterior and posterior rhinoscopic examination and found the nasal cavities free from any more polypi. The boy now talks and breathes normally.

I report this case because it is extremely rare to find such a large polypus in such a young patient and also it is rare not to find some associated polypi in the nasal cavities. The growth without doubt was there at the time of the previous operation one year ago.

340 Stuyvesant Avenue.

## CASE OF EXOPHTHALMIC GOITER CURED BY *X*-RAY.

By SINCLAIR TOUSEY, A.M., M.D.,

NEW YORK.

A case in which no treatment has been required and no return has taken place for seven years is certainly noteworthy.

The patient, Mrs. W. S. B., was accompanied to my office by Dr. I. N. Love of Wilmington, N. C., on September 14, 1905. She was 32 years old, weighed 116 pounds, had a blood pressure of 140 mm. and a pulse of 130. There was moderate exophthalmos; Graef's symptom was marked, the upper lid not following the motion of the eyeball when she looked down; there was such palpitation of the heart that it shook the whole bed and kept her husband awake nights; tremor of the fingers to such an extent that she could not pour out a cup of tea.

The treatment consisted in applications of the *x*-ray and high frequency currents from a vacuum electrode over the thyroid gland. The applications were made three times a week for about three months. Arsenic and strychnine were given as the only medicines and only for a short time. She returned to her home in the South a well woman with a request that Dr. Burbank, then her physician, should watch the pulse and other symptoms and send her for additional treatment if required.

Within a year she was subjected to great anxiety by the illness of her little girl but there was no recurrence of the disease. She makes a trip to New York every winter for examination but each time she has been found absolutely normal. The last time I had an opportunity to show her at a demonstration of *x*-ray dosage before members of the Congress of Clinical Surgeons of North America.

Recently such cases under my care have had the advantage of treatment with a new *x*-ray generator, the invention of which is partly due to a suggestion of mine. It is more powerful than anything I have previously had and is in effect a dynamo producing a constant direct current of from 10 thousand to 110 thousand volts. This means greater speed and safety in radiography and ability to secure simply the penetrating rays for deep seated lesions or the less penetrating rays for surface lesions instead of the mixture of rays produced by previous induction coils and transformers.

850 Seventh Avenue.

**Abortive and Familial Types of Exophthalmic Goiter.**—R. Dumont reports two cases of exophthalmic goiter. One of the patients was an unmarried woman aged 31 years, whose uncle, on the paternal side, had a double exophthalmos. Her symptoms were chiefly a tremor, extreme irritability, congestion of the face, and cyanosis of the extremities, although there was no marked enlargement of the thyroid gland. The second case was that of a male aged 21 years, whose mother was affected with typical exophthalmic goiter. The symptoms in this patient were a moderate tremor, a slight enlargement of the thyroid gland, vasomotor disturbances in the skin, irritability of temper, insomnia, and a unilateral exophthalmos.—*La Policlinique.*

## INFANT MORTALITY.

With the approach of the summer season the health officer should be prepared to combat the mortality among infants. The months of July, August, and September draw a heavy toll on our babies as from one-third to one-half of the baby deaths are recorded during these months. That infant health is a purchasable commodity is clearly shown by the report of the New York State Department of Health, in its monthly Bulletin for March, 1913. Infant mortality as defined by the United States Census Bureau is the ratio of the number of deaths of infants under one year of age, exclusive of still births, to 1,000 children born alive. During the year 1912 the infant mortality in the whole State of New York was 108.9. This represents a marked decrease from previous years. That this decrease is not accidental is rendered probable by the fact that for the last nine years it has been steadily and uniformly decreasing year by year. Thus in 1904 it was 151, and each successive year since then has seen a lowering of the rate of the previous year except in 1910 when the rate almost exactly equalled that of the year before. Comparing city with country it is interesting to note that in 1912 the infant mortality in the country district of the State was only one per cent. higher than in the cities. In this connection, however, New York City taken alone excelled the rest of the State considered as a whole, for the infant mortality of greater New York was only 105 as compared with 108 for the rest of the State. That the general reduction in infant mortality is due to the increasing activities of local health boards in providing pure clean milk for general consumption seems a justifiable conclusion. It is also likely that the establishment of infant welfare stations and the instruction which mothers receive at the same relative to the proper care and feeding of the infant have also played their part in this reduction.

To educate the mothers and to provide pure milk is the dual problem. Although both these difficulties are being gradually met they are still a long way from final solution. The law may be ever so stringent so far as the requirements for pure milk are concerned but perfection can never be reached in the matter so long as the milk business is so cut up among small dealers and the farmers so hard pushed to make decent profits. This phase of the subject was ably presented at the last International Congress of Hygiene and Demography by John B. Williams, Secretary of the Monroe County (N. Y.) Medical Society's Milk Commission. This Commission, after careful investigation of the conditions in Rochester, N. Y., came to the conclusion that competition caused waste, carelessness, and unnecessary labor in the handling of the milk which resulted in a lowering of its quality as well as a material increase in its cost to the consumer. They found by direct experiment that milk could be delivered in their city at about one-fourth the present cost to the consumer, and that such milk could be uniformly relied upon to conform to the proper standards. As their conclusions were based upon a study of the conditions existing on some forty odd farms and among 173 vendors and 5,400 consumers, besides the direct experiment of going into the business for themselves, it would seem that they should be given great weight. If, as they claim, the chief reasons for milk remaining uncertain in quality and high in price to the average consumer are due almost entirely to wasteful and unbusinesslike methods upon the farm, and to the fierce competition among small dealers it would seen reasonable to conclude that the solution of this phase of the problem would consist in State control of both supply and distribution. And why should any one really object to such a movement? The water supply of the towns and cities has long ago been taken over by the municipalities and considered in its true sense the problem of a pure milk supply is as much of a public function as that of the water. So long as competition remains in the business of supplying this necessity of life we can expect that poor milk will always be the only kind which poor people will be able to buy. At the present time this phase of the subject is rendered less acute in many cities owing to the charity of the rich. But this supplying by charitable means what should by rights be within the reach of the poorest purse is only a temporary and at the best a poor makeshift. To control this phase of the situation effectually the State must either own and control the supply and distribution or else these must be given over to some central corporation with supervision of price and manner of conducting the business undertaken by a public service commission. But insured a pure milk supply at a price within the reach of all, the problem of educating the mothers in the proper care and feeding of the infants still remains.

Probably the work already undertaken in the way of establishing infant welfare stations and the activities of the local boards of health in disseminating leaflets containing simple instructions to mothers are the best roads to take in accomplishing the proper care and feeding of the infants. The special Public Health Commission appointed by Governor Sulzer advises in its report that "Each city with a population in excess of 10,000 and having an industrial population should have one Infant Welfare Station for each 2,000 inhabitants." Besides the factors mentioned in the reduction of infant mortality there remains one other of almost as great importance. That is the house fly. The milk may be ever so good and the mother ever so intelligent

and the baby will still sicken of intestinal trouble so long as this pest carries filth and infection. Of course intelligence on the part of the mother will lessen the danger of the fly having access to the food but it cannot eliminate it altogether.

Three remedies then for the still high infant mortality are: (1) State control of the supply and distribution so that good milk can be brought within the reach of all at a price which the poor as well as the rich can afford. (2) Education of the mothers along the lines already undertaken in a small way in some cities and towns. (3) Fly extermination. Of these remedies the public is ready to partake freely of the last two. The first one is perhaps so suggestive of socialism that it will be opposed by many who fear the results of any movement in the way of State control of business undertakings.

## HEART DISEASE AND THE MODERN RUSH.

In the annual report submitted by Dr. Newsholme, the Medical Officer of the Local Government Board in London, the truth well known among physicians is restated—that heart and arterial diseases have in recent years been increasing among those in the afternoon of life; and Dr. Newsholme attributes this to the strain, the worry, the hurry, and the dreadfully high pressure of modern commercialism, all tending to abnormal wear and tear on the precious organ which, with its vessels, must supply to the body its life-sustaining fluid. The nervous system, which is basic for all existence, and which especially controls the circulation, is under constant stimulus. Thus in England, it appears, one-third of the deaths in the age period 55 to 65 come about through damaged myocardium and sclerosed vessels.

Medical men in this country have for more than a decade recognized the phenomena referred to by the English observer. Not to add statistics-delving to the strains above mentioned, we may note simply that the Census Bureau at Washington gives the following percentages which the death rates in the years progressively from 1901-7 inclusive, represent of that in 1900—Circulatory diseases (heart and vessels): 101.2, 105.7, 110.7, 119.8, 120.0, 122.9, 134.1. And our last Census report (issued Sept. 11, 1911) states: "During the last decade there has been a large increase in the number of deaths and death rates from organic diseases of the heart and of the circulatory system in general." As to cities, heart disease is reported to have caused many more deaths in 1907 than in 1906—in Chicago and Boston 13 per cent. more, in New York 29, in Detroit 26, in Philadelphia 5, etc.

A factor coupled in its fatal consequences with the abnormal stress of modern life is, that men of affairs who have come down with pneumonia, grippe, and like infections (the toxins in which are dreadfully disintegrating of the organs and other vital tissues), can simply not be made to take the prolonged rest which is imperative during the convalescence from these diseases. Many of these patients (and elderly men, too) are in their offices when they should most decidedly be in their beds. "Such a fussy lot, these doctors," declared such an one. "Besides, an old horse that once lies down never gets up." He put on his overcoat, went to business, returned that afternoon in collapse, and died next day.

The fault is not here with the doctors, to whom it is not given to command the *zeitgeist*, to dominate the manners and customs of the age. They can but warn against fast living, undue indulgence in indigestibles and intoxicants, and against business habits conducive to such nerve tension as must inevitably wreck the organism to its untimely dissolution; they can but indicate the weak and uncertain pulse, the dyspnea, the blue lips and finger tips, the ashy face, the distended veins in the neck—and tell the dire meaning of these signs.

## THE BLOOD PICTURE OF LYMPHATISM.

One of the greatest desiderata in clinical medicine is a biometric criterion for any one of the so-called diatheses, habits, temperaments, which are believed to underlie most of the chronic diseases. The phenomena believed for years to point to lymphatism, scrofulosis, thymicism, and other related states, while possessing an anatomical substratum, have only represented approximations or averages; and such evidence as they furnished, however considerable, was not sufficient to demonstrate beyond doubt the existence of basic constitutional peculiarities.

Attempts have long been made to see in certain blood pictures something characteristic of these peculiarities. Certain authors have claimed that in lymphatism we have always a lymphocytosis, others eosinophilia. These claims have been based in part on theoretical conditions and also upon confusing a primary lymphatism with secondary conditions due to disorders of the ductless glands.

At a recent session of the Society for Internal Medicine and Diseases of Children, Vienna, Siess and Stoerk described a blood picture regarded by them as quite characteristic of lymphatism (*Berliner klinische Wochenschrift*, March 24). This is as follows: (1) Increase, often pronounced, in the number of blood plates. (2) Distinct diminution in the number of eosinophiles. The other forms of corpuscle show no constant changes and are present within normal limits. By lymphatism the authors refer solely to the so-called status thymico-lymphaticus as a primary anomaly of the anatomical constitution; and not in any way to combinations of lymphatism with other diatheses. In the pure state there is neither lymphocytosis, nor leucopenia. We may at times see a relative lymphocytosis, but this possesses no element of specificity, and is due to a diminution in the number of neutrophiles.

### Proposed Marriage-License Bill.

It is reported that the bill regulating marriage along health lines has been reintroduced in a modified form into the legislature of this State, and it is stated that the bill has been indorsed and is being actively pushed by many organizations working for physical and social betterment. That it should be possible to introduce such a bill is a healthy sign

of the times since it is a proof that public opinion, so hard to arouse, is becoming fully awake to the menace to the well being of the nation and race which exists in the uncontrolled propagation of the unfit. Whether, however, the time is yet ripe for invoking the help of the law in the direction of supervising marriages is another question. The matter is hedged in with so many difficulties that it seems almost impossible, at the present time, to devise practical means of solving the problem. But the significant feature of the situation lies in the fact that the public is taking an active interest in the subject and is beginning to understand that it is one which it intimately concerns. Even if many of the schemes brought forward are unworkable, at least, they show that steps are being taken to endeavor to save the race from deterioration and with the aid of those best qualified to grapple successfully with the problem some practical plan may possibly be evolved.

## News of the Week.

**City Death Rate.**—During the week ending April 26, there were 1,667 deaths reported in New York City, a rate of 16.28 per thousand, as against a total of 1,529 deaths and a rate of 15.42 for the corresponding week of 1912. The increased mortality extended throughout practically all of the age groups, almost one-third of it occurring among children under five years of age. There was a comparatively large number of deaths due to diphtheria, croup, and whooping cough in the Borough of Manhattan, and deaths from diseases of the heart and respiration were also much increased as compared with last year.

**Hospital Cornerstone Laid.**—The cornerstone for the new Greenpoint Hospital at Kingsland Avenue and Bullion Street, Brooklyn, was laid on April 27, by Comptroller Prendergast with appropriate ceremonies. The new building will cost $300,000 and will be six stories high.

**Police Surgeons Investigated.**—The findings of the board appointed by the Curran Committee to investigate the surgical board of the Police Department of New York City were made public on April 27. The board, composed of Dr. E. C. Bray and Dr. C. McCoombs, found much to censure and apparently little to praise. The police surgeons, of whom there are twenty-four, receive a salary of $3,500 a year each, and are eligible for pensions. According to the report some of the bad features of the present system are that the police surgeons have no set hours of duty daily; are not required to live within the districts to which they are assigned, and at times are not available when needed; that no surgeons are assigned to night duty; that they are not required to inspect the sanitary condition of the station houses; that they give only a disciplinary supervision of patients, their chief duties being to make physical examinations of applicants for appointment and retirement, and to determine whether sick leave is to be granted; that there is no proper system in force of keeping medical histories of the men examined; and that the privilege of engaging in outside practice without restrictions and the absence of regulations as to hours of duty have resulted in the surgeons making their work in the department subordinate to their private practice. The constructive recommendations made by the investigators are that the police surgeons be required to devote their entire time to the work, or that at least six hours of duty a day be required, the police work being given preference over private work; that once a year every member of the police force be thoroughly examined to determine his physical fitness; that the surgeons be required to live within their districts and to make monthly inspections of the station houses; and that they be not allowed to treat the families of policemen. The records show that during the year from March 1, 1912, to March 1, 1913, the total days of work lost to the city through sick leave in the Police Department numbered 79,788.

**Faculty Appointments at the College of Physicians and Surgeons.**—At a meeting of the Trustees of Columbia University, New York, held on May 3, the Chair of Bacteriology, made vacant by the death of Prof. Hiss, was filled by the appointment of Dr. Hans Zinsser, formerly instructor in the department under Prof. Hiss and more recently professor of bacteriology at Leland Stanford University.

The following appointments were made also: Professors of Clinical Surgery, Dr. Walton Martin, advanced from associate, and Dr. H. H. M. Lyle; Assistant Professors of Clinical Surgery, Dr. Frank S. Mathews and Dr. William A. Downes; Assistant Professor of Pharmacology, Dr. C. C. Lieb; Professors of Clinical Medicine, Dr. James Alexander Miller, advanced from assistant professor, and Dr Austin W. Hollis; Assistant Professors of Clinical Medicine, Dr. Lewis F. Frissell, and Dr. T. Stuart Hart.

**Personals.**—Dr. Maximilian Herzog of Chicago is to be placed in charge of a research laboratory soon to be established by the Jesuits at Loyola University in that city, for the purpose of testing out alleged cures for tuberculosis and other diseases, and for doing research work, particularly in serum therapy.

Dr. William S. Bainbridge of New York spoke on "Chronic Intestinal Stasis," before a meeting of the Cumberland County Medical Society at Portland, Maine, on April 19.

**Class of '98, N. Y. U. Medical College.**—The quindecennial dinner of the class of 1898, New York University Medical College was held at the Yale club on May 3, 1913. Dr. Harvey Losee of Upper Red Hook, president of the class, was in the chair. Dr. Walter B. Jennings of New York City was toastmaster. Dr. Egbert Le Fevre, dean of the medical school, spoke on "Medical Education," and Dr. Edward D. Fisher also addressed the class, after which each member of the class made a few remarks. It was decided to have a class dinner every five years. Twenty-two men were present.

**New York Society of Anesthetists.**—A meeting of this Society will be held at the New York Academy of Medicine on May 14, at 8:15 P.M. Papers will be read by Dr. J. M. Flint on "Pharyngeal Anesthesia," and Dr. C. J. Pick on "Ethyl-Chloride Anesthesia."

**Northern Medical Society.**—A meeting of this Society will be held May 19 at 8.45 P.M., at 12 Mt. Morris Park West. Papers will be read by Dr. Nathaniel Barnett on "Successful Treatment of Vulvovaginitis in Young Children," and by Dr. Wm. J. Robinson on "Should Venereal Disease Be Reported to the Board of Health?" Followed by general discussion.

**No Labels for Children.**—Pressure of public opinion caused the Board of Health of Kearny,

N. J., to withdraw its proposed ordinance requiring children living in houses in which there were cases of whooping-cough to wear yellow bands around their arms. The proposal was made because of a recent epidemic of the disease in the town, but it met with much opposition from the parents.

**Memorial to the Kaiser.**—In compliance with the German Emperor's expressed wish that all funds subscribed in connection with his silver jubilee next June be devoted to local philanthropic purposes, the executive committee of the Kaiser Memorial Fund in New York announces that the fund will be used toward the establishment of the Kaiser Wilhelm Pavilion, a hospital building now in course of erection as a part of the German Hospital and Dispensary, New York.

**Street Accidents.**—During the month of April forty persons were killed by street traffic in New York City, of whom twenty-two were children. One hundred and sixty-six persons were seriously injured, by far the larger part of the accidents being due to motor cars.

**American Medical Editors' Association.**—The annual meeting of this society will be held June 16 at the Hotel Radisson, Minneapolis, Minn. An interesting program has been prepared, covering items of journalistic as well as general information. The annual banquet will be held on the evening of the 16th at the Radisson Hotel.

**Gifts to Hospitals.**—The Long Island College Hospital, Brooklyn, receives a bequest of $5,000 under the will of the late Josiah M. Fabill of that city.

**Medical Association of Georgia.**—At the annual session in Savannah on April 17 to 19 the following officers were elected: *President,* Dr. Ralston Lattimore, Savannah, *Vice-Presidents,* Dr. J. D. Chason, Bainbridge, and Dr. S. R. Roberts, Atlanta; *Secretary-Treasurer,* Dr. W. C. Lyle, Atlanta. The next convention will be held in Atlanta.

**Louisiana State Medical Society.**—The following officers were elected at the close of the annual meeting in Baton Rouge, April 24: *President,* Dr. Fred J. Mayer, Opelousas; *Vice-presidents,* Dr. A. J. Perkins, Lake Charles; Dr. A. H. Gladden, Monroe, and Dr. W. S. Rutledge, Ruston; *Secretary,* Dr. L. R. DeBuys, New Orleans; *Treasurer,* Dr. E. W. Mahler, New Orleans.

**Medical Society of the State of California.**—Officers were chosen at the annual meeting in Oakland on April 16 as follows: *President,* Dr. Fitch C. E. Mattison, Pasadena; *Vice-presidents,* Dr. Barton J. Powell, Stockton, and Dr. George E. Tucker, Riverside; *Secretary,* Dr. Philip Mills Jones, San Francisco.

**Foundation of the American College of Surgeons.**—A meeting of the organization committee, authorized and appointed at the Clinical Congress of Surgeons of North America, was held at the Willard Hotel, Washington, D. C., May 5, 1913. Dr. Edward Martin of Philadelphia acted as Chairman, and Dr. Franklin H. Martin of Chicago as Secretary. The object of the meeting was stated in the language of the following resolution bringing it into existence:

"*Resolved,* That this largest organization of surgeons on the American continent, the Clinical Congress of Surgeons of North America, shall assume the responsibility of standardizing surgery. This should be accomplished through representative committees and along the following lines: (1) It should formulate a minimum standard of requirements which should be possessed by any authorized graduate in medicine, who is allowed to perform independently surgical operations in general surgery, or any of its specialties. (2) It should consider the desirability of listing the names of those men who desire to practise surgery, and who come under the authorized requirements. (3) It should seek a means of legalizing under national, colonial, state or provincial laws, a distinct degree supplementing the medical degree, which shall be conferred upon physicians possessing the requirements recognized by this law as necessary to be possessed by operating surgeons. (4) It should seek cooperation with the medical schools of the continent which have the right to confer the degree of M.D., under the present recognized standards, and urge these colleges to confer the supplementary degree of surgeon on each of its graduates who have, in addition to their medical course, fulfilled the necessary apprenticeship in surgical hospitals, operative laboratories and actual operative surgery. (5) It should authorize and popularize the use of this title by men upon whom it is conferred, and its use should especially be urged in all directories of physicians, in order that the laity as well as the medical man can distinguish between the men who have been authorized to practise surgery and those who have not."

This committee decided to commit the decision of the desirability of the method of organization, and the accomplishment of an organization which would fulfill the spirit of instructions of the Congress to the strongest representation of surgeons that could be gotten together. The results of the committee's efforts were that five hundred representative surgeons from all portions of the North American continent have consented to become founders of the organization under contemplation, and of this five hundred fully three hundred were present in Washington to fulfill their obligations. The Chairman stated that the object of the meeting was to formulate further and endorse the work that had been done by the subcommittee in regard to the standardization of surgery, for the benefit of the profession and the protection of the public. Every one was in sympathy with the object. The following resolutions were adopted:

"*Resolved,* That the surgeons who were invited to become the Founders of this Corporation are hereby declared Fellows of the College of Surgeons, and shall receive their election by the Board of Regents without further formality.

"*Resolved,* That such other surgeons in the territorial dominion of the College, whose surgeonship can be unquestionably approved by the Committee on Credentials be at once, without the formality of an examination, recommended to and received by the Board of Regents as accredited Fellows of the College of Surgeons.

"*Resolved,* That members of the societies of surgeons and surgical specialties holding accredited positions in the federation of societies constituting the Congress of American Physicians and Surgeons, shall also be accepted as Fellows of the College of Surgeons without the usual formality required by the Board of Regents.

The following resolutions regarding the selection of Fellows were likwise adopted:

"*Resolved,* That the prospective Fellows of the College be divided, for the purpose of classification, into four groups to be designated A, B, C, and D

classes, respectively. The A Class shall consist of the Founders of the College. The B Class shall consist of the members of the special surgical societies constituting the Congress of American Physicians and Surgeons, and one hundred each, nominated by an accredited committee, from the Surgical Section of the American Medical Association, from the Section of Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, from the General Surgical Section of the Clinical Congress of Surgeons of North America, from the Surgical Specialties of the Clinical Congress of North America, from the American Association of Obstetricians of Gynecologists, from the Canadian Medical Association, from the Southern Surgical and Gynecological Association, and from the Western Surgical Association. The C Class shall consist of surgeons of prominence of ten years in the practice of surgery or a surgical specialty, and who, in the opinion of the Committee on Credentials, are eligible for Fellowship in the College without formal examination. The D Class shall consist of surgeons who cannot, in the opinion of the Board of Regents, be classified under A, B, or C divisions, and for whom the college must establish an examination or other evidence of acceptable qualifications.

"*Resolved*, That the Board of Regents through the Committee on Credentials limit the admission of Fellows to classes A, B, and C until the Board of Regents formulates a standard of requirements for Class D and reports the recommendations back to the Board of Governors for approval at a meeting to be called by the Board of Regents at the time of the next meeting in Chicago, November, 1913."

The following officers were elected: *President*, Dr. J. M. T. Finney, Baltimore, Md.; *Vice-President*, Dr. Rudolph Matas, New Orleans, La.; *General Secretary*, Dr. Franklin H. Martin, Chicago, Ill.; *Treasurer*, Dr. A. J. Ochsner, Chicago, Ill.

*Board of Regents:* Dr. George E. Brewer, New York City; Dr. Geo. E. Armstrong, Montreal, Can.; Dr. John B. Murphy, Chicago, Ill.; Dr. Edward Martin, Philadelphia, Pa.; Dr. F. J. Cotton, Boston, Mass.; Dr. Herbert A. Bruce, Toronto, Ontario; Surgeon-General W. K. Stokes of the Navy; Dr. William D. Haggard, Nashville, Tenn.; Dr. Geo. W. Crile, Cleveland, Ohio; Dr. McKechnie, Vancouver; Dr. Charles H. Mayo, Rochester, Minn., and Dr. Harry Sherman, San Francisco, Cal.

**Medical Society Elections.**—Medical Association of the State of Georgia: Annual meeting at Savannah on April 17 and 18. Officers elected: *President*, Dr. Ralston Lattimere, Savannah; *Vice-Presidents*, Dr. J. D. Chosen, Bainbridge, and Dr. S. R. Roberts, Atlanta; *Secretary-Treasurer*, Dr. W. C. Lyle, Augusta.

South Carolina State Medical Association: Annual meeting at Rock Hill on April 15 to 18. Officers elected: *President*, Dr. William Weston, Columbia; *Vice-Presidents*, Dr. J. R. Miller, Rock Hill; Dr. W. Ouzts, Edgefield; and Dr. J. H. Miller, Cross Hill; *Secretary-Treasurer and editor of the Medical Journal*, Dr. E. A. Tines Seneca.

Plymouth District (Mass.) Medical Society: Annual meeting at Brockton on April 17. Officers elected: *President*, Dr. Charles E. Lovell, Whitman; *Vice-President*, Dr. Nathaniel C. King, Brockton; *Secretary-Treasurer*, Dr. Alfred C. Smith, Brockton.

Middlesex South District (Mass.) Medical Society: Annual meeting on April 16. Officers elected: *President*, Dr. Godfrey Ryer, Malden; *Vice-President*, Dr. William D. Swan, Cambridge; *Secretary*, Dr. Lyman S. Hapgood, Cambridge; *Treasurer*, Dr. Charles A. Dennett, Arlington.

**Obituary Notes.**—Dr. J. Lester Carney of Brooklyn, N. Y., a graduate of the Long Island College Hospital, Brooklyn, in 1888, and a member of the New York State and Kings County Medical Societies, died at his home on April 22, aged 62 years.

Dr. John Coert Dubois of Hudson, N. Y., a graduate of the New York University Medical College in 1857, died at his home on April 29, aged 81 years.

Dr. Egbert D. Doolittle of Easton, Penn., a graduate of Bellevue Hospital Medical College, New York, in 1870, a member and former president of the Lehigh Valley Homeopathic Medical Society, and a member of the Pennsylvania State Homeopathic Medical Society, died at his home from valvular disease of the heart, on April 12, aged 66 years.

Dr. Robert Campbell of Jamaica, New York, Registrar of Vital Statistics in the Queens Borough Division of the Department of Health of New York City, at his home on April 18, aged 62 years.

Dr. Charles James Fox of Hartford, Conn., a graduate of New York University Medical College in 1876, a member of the American Medical Association and of the Connecticut State and Hartford County Medical Societies, secretary of the Board of United States Examining Surgeons of Hartford, and formerly president of the National Association of United States Examining Surgeons, died after a short illness on April 19, aged 59 years.

Dr. Samuel Bell of Beloit, Wis., a graduate of the University of Michigan, Department of Medicine and Surgery, in 1864, a member of the Wisconsin State and Rock County Medical Societies, and president of the first Board of Health in Wisconsin, died at his home on April 18, aged 72 years.

Dr. Oliver H. Koons of Brooklyn, N. Y., a graduate of the Jefferson Medical College, Philadelphia, in 1883, died at his country home in South Orange, N. J., on April 23.

Dr. Orlando W. Sutton of Bath, N. Y., a graduate of the Eclectic Medical College of the City of New York in 1891, died suddenly at his home on April 25, aged 64 years.

Dr. Marion D. Carter of Los Angeles, Cal., a graduate of the Missouri Medical College, St. Louis, in 1882, and a member of the California State and Los Angeles County Medical Societies, died in the Crocker Street Hospital, Los Angeles, as the result of injuries received in an automobile accident, on April 9, aged 56 years.

Dr. Hezekiah John Crumpton of Piedmont, Cal., a graduate of the Rush Medical College, Chicago, in 1871, and a member of the American Medical Association and of the California State and Alamedo County Medical Societies, died at his home on April 8, after a short illness, aged 84 years.

Dr. Harriet Adaline Thompson of Bridgeport, Conn., a graduate of the Woman's Medical College of Pennsylvania, Philadelphia, in 1893, and a member of the Connecticut State and Fairfield County Medical Societies, died at her home on April 18, as the result of injuries received in a fall a few days before, at the age of 64 years.

Dr. Joel B. Yingling of Baltimore, Md., a graduate of the University of Maryland School of Medicine, Baltimore, in 1878, died at his home on April 14, aged 65 years.

Dr. W. G. Carter of West Liberty, Ky., the oldest resident of the town, died at his home after a short illness on April 12, aged 92 years.

Dr. Winfield S. Sayler of Gratis, Ohio, a graduate of the Medical College of Ohio, Cincinnati, in 1880, and a member of the Ohio State and Preble County Medical Societies, died at his home following amputation of his right leg for blood poisoning, on April 18, aged 60 years.

Dr. Frank Graham of Lisbon, Ohio, a graduate of the Medical College of Ohio, Cincinnati, in 1880, and a member of the American Medical Association and the Ohio State and Columbiana County Medical Societies, died in the Youngstown Hospital, following an operation for disease of the stomach, on April 13, aged 53 years.

Dr. Bryan B. Ashbrook of Pataskala, Ohio, a graduate of the Columbus Medical College in 1882, was instantly killed on April 21, when the automobile which he was driving was struck by a special train on the Pennsylvania Railroad. Dr. Ashbrook was 56 years of age.

Dr. P. K. Wortham of Waco, Texas, a graduate of the Missouri Medical College, St. Louis, in 1879, died at his home after a long illness, on April 8, aged 75 years.

Dr. John W. C. O'Neal of Gettysburg, Pa., a graduate of the University of Maryland, School of Medicine, Baltimore, in 1844, died at his home on April 25, aged 92 years.

Dr. Simon Hubler of Scranton, Pa., a graduate of the University of Pennsylvania, Department of Medicine, in 1879, died at his home on April 24, aged 66 years.

## Obituary.

### FRANCIS PARKER KINNICUTT, M.D.,

NEW YORK.

Dr. Francis Parker Kinnicutt of New York, professor of clinical medicine in the College of Physicians and Surgeons, Columbia University, died suddenly on May 2, from apoplexy, while attending a meeting of the Practitioners' Society.

Dr. Kinnicutt was born in Worcester, Mass., on July 13, 1846, and pursued his academic studies at Harvard University, receiving the degree of A.B. in 1868 and of A.M. in 1869. He then entered the College of Physicians and Surgeons, New York, graduating in 1871, and followed this with post-graduate work in Heidelberg and Vienna in 1873-74, after which he began the practice of medicine in this city. In 1893, Dr. Kinnicutt was made professor of clinical medicine in the College of Physicians and Surgeons, and he served also as attending physician to the Presbyterian Hospital, consulting physician to St. Luke's Hospital, the Woman's Hospital, the Hospital for the Ruptured and Crippled, the Babies' Hospital, the General Memorial Hospital, Minturn Hospital, and the Vassar Brothers Hospital, Poughkeepsie, and as a member of the medical advisory board of the Department of Health of the City of New York and of the advisory board of Sailors Snug Harbor. He was a member of the American Medical Association, the New York State and County Medical Societies, the New York Academy of Medicine, the Association of the Alumni of the College of Physicians and Surgeons, and the Association of American Physicians, of which he was president in 1907.

### LONDON LETTER.

(From Our Regular Correspondent.)

ROYAL COMMISSION ON THE LONDON UNIVERSITY REPORT—FIBROSITIS, HARVEIAN LECTURE—ANTI-VIVISECTIONISTS' LIBEL ACTION—NAVAL MEDICAL DIRECTOR—LONDON HOSPITAL—OBITUARY.

London, April 18, 1913.

The Royal Commission on University Education in London has issued its final report. It pronounces the present organization of the London University to be "defective" and recommends a complete new constitution. The defects mainly arise from the relations of the internal and external sides and originate in the Act of 1898. The councils of the two sides are dominated by incompatible ideals, the former holding that training in a university under its teachers is the essential of university education; the latter that examinations after education in other institutions may suffice to determine whether a candidate has attained a position entitling to a university degree. The history of the London University is largely the history of this dispute. At first it was an examining body for the technical colleges it recognized and in general education for all who chose to become candidates. By multiplying examinations and fixing a high standard it was sought to make its degrees equally esteemed with the older universities. Success was not secured in this, the prestige of the ancient foundations having scarcely any relation to their examinations. The medical degrees of the London University have all along maintained a high position as certificates that the holders have acquired extensive knowledge, though it has been felt that this was rather more theoretical than practical—the result of more book work than clinical instruction. In the commissioners' new scheme a Faculty of Medicine is to be constituted when funds are available for professors and to obtain control of one or more medical schools. The reorganization thus proposed seems to be the importation of the German clinic and is sure to be opposed as inferior to the independent and competitive London schools. The commissioners do not deny that our physicians and surgeons use the aids science can give for diagnosis and treatment, but only that they do not attack the problems of disease, and so they want to set a professor over them. Is not that just what might be expected from people ignorant of the history of London medical teaching and practice?

The report has only been out two days and more time is needed to appreciate its merits or demerits, but already I hear strong condemnation of it so far as medical matters are concerned. The present external graduates will, doubtless, organize an opposition to a scheme which clearly tends to exterminate them.

The Harveian Society of London's lecture in commemoration of Harvey was this year delivered by Dr. A. E. Luff of St. Mary's Hospital. He took for his subject "The Various Forms of Fibrositis and Their Treatment," an excellent choice, as we have of late been talking a good deal about the maladies dealt with; viz., the more or less chronic affections generally labelled "rheumatic" but which the lecturer laid down at the outset are undoubtedly not the sequel of acute rheumatism and are in no sense connected with it. The pathology of these cases is an inflammatory hyperplasia of the white

fibrous tissue (hence the name) associated with exudation and proliferation of the connective tissue elements leading to swelling and thickening of the affected fibrous tissues. This may undergo absorption or pass on to the formation of nodules and patches of thickening. The articular structures (membrane, cartilage, bone) are not primarily affected, but the fibrous tissues of joints, muscles, and bones, especially the aponeuroses and insertions of the muscles, the sheaths, the bursæ, fascial, and fibrous ligaments and capsules of joints, and the periosteum. The swollen part is painful, tender, and may sometimes be felt or evidenced by elevation of the skin. Pressure or movement, especially sudden, are extremely painful, from compressing or stretching of the inflamed tissues or sensory nerve filaments. The causes of local fibrositis the lecturer considered cold, damp, and wet, extreme degrees of heat or cold, injuries, absorption of toxins from the alimentary tract, tonsillitis, pharyngitis, influenza, or febricula. This is a fairly comprehensive list and suggestive of variety of symptoms which inflammation of the white fibrous tissue may produce in any part of the body and leading the lecturer to the description of different forms of fibrositis. First of them he considered muscular rheumatism which has attained different names, according to locality, as lumbago, stiff neck, growing pains, and other names prefixed to "rheumatism" (intercostal, etc.). Pains in the shoulders or arms may be a moderate inconvenience or render the sufferer to a great degree helpless. Dr. Luff calls them fibrositis, as he does a common form of headache affecting the occipital, temporal, and cranial or other aponeuroses. Depuytren's contraction, often ascribed to gout, but in which he has never met with gouty signs, he considers is fibrositis, and so is the analogous affection of the plantar fascia. When this last affects the fascia at the os calcis we have a troublesome form of painful heel which may result in a bony spur. Bursæ are liable to the same affection with pain and other symptoms according to their locality. Dercum's disease or adiposis dolorosa is an example of the same lesion in the subcutaneous tissue as recently shown by Ralph Stockman. In the joints chronic fibrositis is common in the knuckles of those engaged in hand labor or subject to damp surroundings. Excrescences or pads on the finger joints usually are found on both hands in size from a split pea to half a hazel nut, sometimes painless, oftener not so. They seem to have no connection with gout or rheumatism, contrary to the popular belief, but are more allied to Dupuytren's contraction and often accompany it. Chronic villous synovitis is not claimed as a fibrositis. It is often mistaken for rheumatoid arthritis but may be distinguished by the crepitus on movement which is merely a creaking—not a bony grating, for there is no erosion of cartilage and no eburnation of bone.

For treatment Dr. Luff advised rest according to the severity and the locality of the attack, confinement to bed, strapping or bandages to keep special joints immovable. Of drugs a saline aperient to begin and repeated as necessary. Salicylates he pronounced of little value. Aspirin to relieve pain if severe, for no other use. Iodide of potassium he held to be the most valuable drug which seemed to remove the hyperplasia and serous exudation. Full doses are needed, 10 or 12 grains with tonics (nux or glycerophosphate). If iodism occur one of the organic compounds may be tried. Of fibrolysin his later experience has not supported the rather guarded favorable opinion he formerly expressed. Locally, hot fomentations are good and a mixture of chloral, menthol, and camphor may be painted on the painful part. Iodine paint may be used and a liniment of aconite, belladonna, and chloroform may be applied on lint. Heat and electrical treatment are powerful. Heat should at once be followed by ionization with iodine ions, the most effective in his experience on fibrous thickening and deposits. Lithium iodate and sodium salicylate may be introduced in the same way. Massage and exercises when they cause no pain may be applied to the tissues around the joints. Diet, spa treatment, and other general points were mentioned. In a few cases of nodules surgical measures have been resorted to.

I mentioned above that we had been talking of fibrositis so I may as well add that it was before the Royal Society of Medicine at the beginning of the year. Stockman has perhaps done the most to settle the pathology and show that the nutrient vessels are affected. At least there is endarteritis and periarteritis of them which may perhaps be set up as some toxin conveyed in the blood. Searching for this Goadby massaged the muscles involved and followed up by careful examination of the urine in which he reports that he found streptococci and other organisms, one of them peculiar. There is evidently room for further research.

I may add that thyroid extract has been used successfully in a number of the "rheumatic" complaints touched upon in his Harveian lecture although Dr. Luff did not name it. At the French Academy in January Mr. Gilbert reported five successes out of seven cases of Dupuytren's contraction.

The antivivisectionists' action against the *Pall Mall Gazette* for libel (technically Lind-af-Hageby) is not concluded. Yesterday was the thirteenth day of trial and it was then adjourned until next week. Just think of it! A judge and jury occupied for more than a fortnight over such a "cause." Miss Lind chose to conduct her plaint herself. Thus she had the privilege of the opening speech of which she fully availed herself by relating her own life and the horrors she had seen, but which did not at first extinguish her desire to pursue further. She also, as her own counsel, had the examination of her witnesses and the cross-examination of defendant's. She managed so well that the judge had to tell her she could not make a speech about every paragraph and she must proceed in a less lengthy way when a juryman interjected he quite agreed and counsel said they had had a four-days' opening. Later the judge had to complain that anonymous letters had been sent to him—which he did not read, however. So plaintiff put forward a number of witnesses who testified against vivisection and some added vaccination and thus altogether she obtained reports of her notions in the newspapers for ten days and so much more to come. Does it not seem that the action is merely brought as a grand advertisement of her society, her journal, and her pamphlets? Costly, perhaps, but in the view of the fanatics well worth the money.

Surgeon-General William May, C. B., succeeds Surgeon-General Sir J. Porter, K. C. B., as Director-General of the Medical Department of the Navy.

On Sunday last the Rector of St. Paul's, Deptford, unveiled a tablet "In memory of John Harrison,

founder and first surgeon of the London Hospital, who died in 1753 and was buried in this churchyard. His body lies here. His work continues at the hospital." It is now the largest hospital in London.

Sir H. R. Swanzy, the eminent Dublin ophthalmologist, died on the 12th inst. He was president of the Royal College of Surgeons of Ireland in 1906-8 and was knighted in 1907. Educated at Dublin University, he took the M. B. in 1865, the year he came of age and the next year the license of the college. After further studies in Vienna and Berlin and as a surgeon in the Prussian army he proceeded to the Fellowship of his college and M. A. of the University of which at a latter period he was made Honorary M. D. as he was of Sheffield University, D. Sc. His great work was at the Royal Victoria Hospital, though the Adelaide and others were indebted to him. His "Handbook of Diseases of the Eye" will be well known to you as will, no doubt, many of his important contributions to the societies and journals, for his reputation was world-wide. He was to have been president of the Section of Opthalmology of the International Medical Congress here next August, but he has passed away and the Dublin school of which he was so great an ornament claims the sympathy of the profession everywhere.

Dr. C. E. Shaw, of the Belfast Ophthalmic Hospital and lecturer on his specialty at the Queen's University, died on the 10th inst., at the early age of 49. He had been in delicate health for a long time, but he continued the unequal struggle with courage to the last, contributing largely to societies and literature. His book on "Diseases of the Eye" published in 1895 has maintained a good position.

Lieutenant-Colonel F. G. Maidment, late of the Indian Medical Service, which he entered in 1886, has died at the age of 54. He took part in the Burmese Expedition of 1887-9 as well as in that of China in 1900.

Major J. J. C. Watson, M. D., late of the Royal Army Medical Corps, has died at the age of 51. He joined the corps in 1885, attained the rank of major in 1898. In 1900 he served with the North China Field Force and took part in the relief of Tientsin and Peking, was mentioned in despatches and received the medal with clasp, as well as the Companionship of the Order of the Indian Empire. He retired in 1910.

5. The Medical Milk Commission of Boston. R. I. De Normandie.
6. Discussion of Papers of Professors Jordan and Foord and of Dr. De Normandie. J. L. Morse.

1. **Trichinosis.** T. F. Leen notes that Zenker in 1860 was the first to report a case of this condition. The symptom-complex may be divided into three parts corresponding to the life-cycle and pathology of the worm. The early symptoms are inconstant. General constitutional and gastroenteric disturbances are the rule. Discomfort, anxiety, dull heavy headaches, dizziness, nausea and vomiting, choking sensations, chillness, and diarrhea, with more or less violent colicky abdominal pains, are present. The vomiting and diarrhea may become intense, and the latter may be followed later by obstinate constipation. The appetite usually disappears. During this period of lassitude an increasing fever appears. Occasionally very early an intense lameness of the muscles appears, in the flexors, in the neck, and in the lumbar region. When this and the diarrhea subside, the patients think they are convalescing and some try to work, but are compelled to go to bed. This muscle-lameness appears before the beginning of embryo-wandering, and cannot be explained by muscle-invasion. The most important pathognomonic sympton, quite constant and often generally the first, is the edematous swelling of the eyelids and of the face. Seldom is it lacking and first appears on the seventh day. Somewhat later, from the ninth day on, there is edema of the extremities, more often the legs than the arms, and as well at times the scrotum. The lid edema after some days disappears and may return later, but that of the legs is obstinate and persists a long time into convalescence. Delirium has been noted in a few fatal cases, accompanied with violent attacks of dyspnea. A meningitic picture is present in some cases. Epigastric pain occurs in the second week and is ascribed to the migration of the young brood to the diaphragm. Complete skin anesthesia, lasting for a few days, has been reported, and itching and paresthesia have been noted occasionally. A characteristic symptom is profuse sweating. The blood changes are important. The first stage shows a polycythemia and a polychromhemia, and later a mild anemia develops. There is a leucocytosis which is due to the great increase in the eosinophiles. The severer the disease the greater the eosinophilia. The treatment of trichinosis is as follows: If only a short time has elapsed after the patient has eaten the infected food, copious stomach washings and thorough catharsis should be tried. Strong antithelmintics, such as santonin, extract of male fern, glycerine, and benzol may be given in frequent large doses. Cathartics are given, as calomel, compound infusion of senna, castor oil, etc., to keep the intestine thoroughly clean and wash away any worms which have temporarily lost their grip. Salvarsan and neosalversan are well worthy of trial to kill the embryos in the blood. Colloidal silver in doses of 4 to 6 c.c. of a 2 per cent. solution has been tried intravenously in order to destroy the embryos.

2. **The Leucocyte Count in Osteomyelitis and Tuberculous Osteitis in Children.**—E. W. Fiske has found that the routine examination of children with tuberculosis of the bones and osteomyelitis, two-thirds of the cases in both diseases being in an acute stage, shows an average white count of 11,600 for the former and 16,200 for the latter, a significant difference of about 5,000 leucocytes. That this difference is constant, and is a reliable factor in diagnosis, is shown by the fact that in osteomyelitis but 24 per cent. of the counts were below 12,000, as compared with 66 per cent. in tuberculosis, while 39 per cent. of the former were over 18,000 and but 13 per cent. of the latter over 15,000. This difference is still more emphasized in the acute cases, which make up the majority seen in hospital practice, the average of osteomyelitis being 22,200 and for tuberculosis 11,400, a difference of nearly 11,000.

10. Ointment in Granulating Wounds. G. B. Massey.
11. Syphilis. H. M. Greene.
12. Morphine in General Practice. C. J. Douglas.

1. **Inoperable Primary Carcinoma of the Breast.**—G. E. Pfahler concludes that in inoperable cases of

carcinoma of the breast, *x*-ray treatment offers a reasonable hope of relieving the patient of the symptoms of the disease, prolonging life, and possibly causing complete disappearance of the disease. Patients have been relieved of the symptoms of the disease for from one to eight years. No other method of treatment has ever accomplished as much in this class of patients. A careful mastery of technique is essential to success.

2. **Intravesical Diagnosis and Treatment.**—L. Buerger states that it was with a view to making certain operative procedures in the bladder feasible through the cystoscope that he began working some five years ago. It soon became apparent that the catheterizing cystoscope, even though it was provided with a single catheter outlet, would have to be modified so as to permit of the introduction of instruments of adequate size. Two types of operating cystoscope were then developed. One of these was provided with two sheaths (a convex and a concave) and its capacity was adequate for a No. 12 French catheter. The second type was fitted with an angulated eye piece, thus permitting the introduction of straight instruments. The author has devised a series of instruments for the purpose of the ablation of tumors, for the excision of callous refractory ulcers, for the dilatation of strictures of the ureter, for expediting the passage of ureteral calculi, for the removal of foreign bodies and calculi, for the cure of papilloma by a snaring process, and for the diagnosis of renal tuberculosis by microscopical examination of excised pieces of the ureteral orifice.

3. **Rectal Operations Under Local Anesthesia.**—W. F. Burrows notes there are three sequences of anorectal operations done under general anesthesia which are absent when such procedures are performed under local anesthesia. Whereas with the former, shock and reflex impulses are so marked that voluntary micturition is frequently impossible for a day or more, requiring catheterization of the patient with its concomitant dangers of cystitis and kidney infection, with the latter no such difficulty is encountered, and, in the author's experience, without exception, voluntary emptying of the bladder is possible. Second, the loss of weight and strength which accompany the use of ether or chloroform, due both to the toxic effect of the anesthetic and the enforced confinement to bed, is entirely absent following operations performed by the author's method, which necessitates no toxemia nor confinement. Lastly, the indications for making the bowels constipated for a period of two to four days or more, thought so necessary in major operations performed for minor rectal conditions and leading to abdominal discomfort, distention, and perhaps autoinfection, are rarely present. The ideal solution for local anesthesia is easily sterilized, effective, nonpoisonous, and one which causes a minimum amount of postoperative reaction and pain. Cocaine, novocaine, tropacocaine, betaeucaine, stovaine, alypin, quinine and urea hydrochloride, saline, or distilled water may be used. Novocaine is satisfactory, and, in a 0.25 or 0.5 per cent. solution, as generally used, is a safe anesthetic. Quinine and urea hydrochloride, satisfactory in selected cases, causes undue swelling, at times sloughing and delayed repair at others. Local anesthesia leads to less delay among patients in obtaining the relief, which, on account of the fear of pain or of the supposition that the use of a general anesthetic is required, they have neglected to secure until complications have frequently ensued and the health has suffered. When one comprehends that there are but three or four rectal and anal cases in a hundred, apart from cancer, which do not permit of ready relief and cure through operation, if required, performed under local anesthesia, there will no longer exist uncertainty in regard to the proper procedures to advise. Only too often in the past has dissatisfaction arisen over confinement exceeding the time thought necessary.

5. **Orbital Cellulitis.**—A. Wiener states that it is a well known fact that the nose and its accessory cavities are etiologically responsible for many of the orbital and ocular complications with which we meet. The antrum of Highmore, the anterior ethmoidal cells, and the frontal sinus are in close proximity to the floor, inner wall, and roof of the orbit. On the other hand, the posterior ethmoidal cells and the sphenoidal sinus are in immediate contiguity to the posterior half of the inner wall, the posterior part of the floor and roof of the orbit, and optic foramen. When disease exists in these sinuses, infection may be carried into the orbit, either through the vascular return which empties into the superior and inferior ophthalmic veins, or by caries and destruction of the intervening bony wall. Dehiscences, gaps, and defects in the osseous floor of the frontal sinus or lamina papyracea of the ethmoid may also permit infectious material to find its way into the orbit. A fatal case of this nature which recently came under his care is reported by the author.

8. **Electricity in Rectal Diseases.**—F. H. Williams concludes that electrolysis is a safe and painless method of treating all cases of varicose internal hemorrhoids. Patients are not confined to the room, or detained from their usual duties while under treatment, except in extreme cases. Weak and aged patients who are unable to take a general anesthetic stand electrolytic treatments admirably. Electrolytic treatments are not as easily given as electrocautery treatments, the former requiring more time and more exactness of technique. There is no hemorrhage during or after treatment. Ulceration, stricture, fistulæ, or abscesses have never been observed as a sequel to this method. Records covering a period of ten years after treatment indicate that cures are permanent.

9. **Treatment of Tuberculous Bone Abscesses and Sinuses with Tuberculin.**—W. S. Niblett has been systematically using old tuberculin locally with good results. This method of treatment is very stimulating to the sluggish granulations and converts the creamy pus into serosanguineous pus. After two or three injections the sinuses appear healthier and the discharge is markedly decreased. The technique is very simple and consists in the injection of about 120 minims of 1 to 500 old tuberculin solution into the depths of the sinus by means of a syringe or a small, soft rubber catheter, which is withdrawn as the injection is made, in the endeavor to bring the tuberculin into immediate contact with the walls of the sinus. After three or four injections the strength of the tuberculin is increased from 1 to 500 to 1 to 250, or even 1 to 50. This is governed by the reaction, both local and systemic. The injections are given biweekly. There is some systemic as well as local reaction after the first injection. The patient's temperature may reach 101° or 101.5° F., with some lassitude, but this is less marked after the first two or three injections, and usually disappears entirely after subsequent treatments. Great care must be taken to use a weak tuberculin solution, as it is desirable to avoid a rise of temperature. The sooner one gets the sinus closed or thoroughly plugged, aside from the treatment of the granulations with the tuberculin or some other substance to stimulate the walls of the abscess or sinus, the better it is for the patient.

10. **Treatment of Granulating Wounds by Means of Ointments.**—G. B. Massey after many experiments with various ointments has selected two as the most useful for the small and large wounds remaining after the destruction of malignant growths, and their occasional use in other wounds has shown their general value also. One of these, and the most important, is zinc oxide ointment diluted with four times its weight of semifluid petrolatum. This is used on the wounds so freely that it alone comes into contact with the granulations. A gently antiseptic, gently stimulating action will be shown in a few

hours. No water or other irritating substances are allowed to come in contact with the wound surface, and only the surrounding skin is cleaned with soap and water or alcohol when the dressing is changed. If an abundance of the ointment is used the wound will be self cleansing. The other ointment, which is sometimes used for a time when the diluted zinc oxide ointment appears to have overreddened the granulations by overstimulation, is the boric acid ointment of the pharmacopeia; but this is seldom required.

1. **Prevention of Heart Strain During Anesthesia.**—W. D. Gatch, D. Gann, and F. C. Mann conclude that the Trendelenburg position is harmless for patients with normal hearts, provided their respiration is free and unobstructed. In case of partial or complete failure or obstruction of the respiration, the patient should at once be placed in the horizontal or semirecumbent posture. The Trendelenburg position should be used only with the most extreme caution in cases of cardiac disease. To prevent a too sudden inflow of blood to the heart the patient should be placed gradually in the Trendelenburg position, and to prevent a sudden failure of the circulation the patient should be gradually lowered. The effect of struggling and of pressure on the abdominal viscera is to increase greatly the strain on the heart. These agencies also are harmless to injure patients with normal hearts and arteries, provided the breathing is adequate to prevent cyanosis. During asphyxia all of the three agencies considered tend to produce a rapid dilatation of the right side of the heart. A heart once overdilated while in a state of asphyxia is temporarily, and possibly permanently, injured. This is suggested as a possible explanation of certain cases of sudden postoperative death. Robust patients should be given morphine, and alcoholic patients morphine and alcohol before operation, and should be anesthetized without being permitted to become cyanotic. Patients with cardiac disease, pneumonia, or empyema should be given morphine before operation and should be anesthetized cautiously and slowly in the sitting or semirecumbent posture. The production of a hypercapnia protects to a marked degree from respiratory failure during anesthesia, and hence from the harmful effects of the agencies which promote a free supply of blood to the heart. Under ether certainly, and probably under nitrous oxide, cardiac failure is always secondary to asphyxia. Morphine and moderate ether narcosis do not impair vasomotor tone in man. Hence in the absence of hemorrhage the semiupright posture is not harmful to man under this form of anesthesia.

4. **Urethral Caruncle.**—C. G. Buford points out that the results of annoyances from caruncles deserve much consideration. Loss of sleep from frequent urination, urethral tenesmus and multiple vague pains may destroy the health of an otherwise healthy woman "and in her desperation she submits to anything offering relief." The condition is usually mistaken for urethritis or cystitis. The treatment is not that of irrigation of the bladder, the dilatation of the urethra, or the use of caustics. Temporary remissions come not from these treatments but in spite of them. Complete excision well outside and under the tumor should be performed and the wound closed so as to leave the least possible cicatrix and a wide external meatus, thus providing against stricture. When the distal portion of the urethra is excised in a circular way it should not be allowed to retract; the skin of the vestibule should be drawn in and united to the urethra by horsehair sutures. When caruncles are not completely removed they recur. Instances are recorded of primary carcinoma occurring in the urethra or periurehtral glands from which caruncles had been excised.

6. **Simplified Transfusion.**—S. Pope after mentioning the technical difficulties of transfusion with the usual methods, those of the Carrel suture and the Crile and Elsberg cannulas and even the Brewer tube, states that to obviate the difficulties, there have been used for some time past in the research laboratory of the medical department of the University of California, a rubber tube with small glass tips and with its interior lined with a mixture of petrolatum and paraffin as a connecting medium. A piece or rubber catheter will do for the cannula and the glass tips are easily drawn from glass tubing over the Bunsen flame and may be of various calibers. They should be slightly flared at the point and smooth at each end. Both tube and tip should be boiled in equal parts of white petrolatum and paraffin. Great caution should be observed that this coating is evenly distributed and that no bare spaces occur in the cannula. The usual technique of transfusion may then be followed. During the transference of blood the tube can be both seen and felt to pulsate vigorously. Reciprocal transfusion in dogs has been kept up for over half an hour without evidence of clotting and for fifteen minutes in the human being with the veins still spurting on disconnection. With this method, transfusion is hardly more difficult than an intravenous injection. Should thrombosis supervene, as might happen with any method with imperfect technique, it would be unwise to dislodge the clot without disconnecting the cannula.

8. **Retrocecal Appendicitis.**—By J. N. Jackson. (See MEDICAL RECORD, January 25, 1913, page 180.)

9. **Vaccination Against Meningitis.**—J. H. Black finds that prophylactic vaccination against meningitis produces a high degree of immunity in most cases, this immunity being demonstrable at the end of one year. Some individuals may show an actual increase in immune bodies at the end of one year over those demonstrable soon after vaccination. Fixation occurred with the serum of a positive control who had recovered from meningitis but this fixation did not reach as high dilutions as did that of some of those vaccinated. This had previously been found also in other individuals who had recovered from the disease. Experimental evidence warrants one in concluding that prophylactic vaccination is a measure of the greatest value in the control of epidemic meningitis.

10. **Medical Ethics.**—A "Physician's Wife" alludes to the scant attention paid to the teaching of medical ethics in medical colleges. She states that during a trip through Europe she reached Vienna one day and drove out to a cemetery where many illustrious dead are buried. In walking through one of the avenues she found the grave of Virchow on which lay a large wreath of fresh flowers; on the ribbon attached she read the words: "To the master from his affectionate students." Virchow lived, labored, and died in Berlin.

11. **Migration of the Omentum.**—A. E. Hertzler discusses the causes of the movement of the omentum toward areas of inflammation in the abdomen which migration has been supposed to be due to peristalsis, though this is not proven. A constant factor in the migration of the omentum is that it moves only toward areas which are injured and then only when the injury is attended with the formation of a fibrinous exudate and the accompanying cellular infiltration. Where these two are not found migration of the omentum does not occur. If there is necrosis there is no attachment of the omentum. The author explains these movements on the basis of the influence of the cells and the fibrin-forming elements and not of any peculiar inherent properties of the omentum. Cornpith migrates in the abdomen under the same conditions. The migration depends on the preliminary formation of fibrin, and the movements are produced by the same forces that attract sells to any field of inflammation. The carrying along with them of the omentum network is purely accidental.

12. **Surgery and Typhoid Carriers.**—T. J. Leary presents the following conclusions: The removal of the gall bladder and the cystic duct as a means of clearing up chronic typhoid carriers is a very valuable one and should be given further trial by military and civil surgeons. The treatment of all typhoid carriers should be carried out only in conjunction with the laboratory men and the different medicinal treatments, more especially the continued typhoid vaccine treatment, should be carried out thoroughly in the beginning. These methods failing, all typhoid carriers should either be kept quarantined or be operated on for removal of the gall-bladder and all of the cystic duct. Only time and a larger series of cases will determine whether or not the removal of the gall-bladder and the entire cystic duct will clear up all of these cases. The author has had the opportunity of carrying out this operation on only two chronic typhoid carriers, and both of these cases cleared up within nine days. No after-effects followed the removal of the gall-bladder and cystic duct in either case.

7. The Use of Sugar in Heart Disease. S. E. Denyer.
8. Freud's Theory of Dreams. W. Brown.

2. **Morbid Anatomy of Periodontal Disease.**—J. F. Colyer states that the conclusions to be drawn from the examination of specimens in man and animals are the following: The bone lesion is a progressive rarefying osteitis commencing at the margin of the alveolar process. The disease is purely local in origin and has its immediate cause in the formation of stagnation areas around the teeth. The varying density of the bone influences the rate of destruction.

3. **Abdominal Pain in Infants.**—E. Pritchard notes that an infant cries for other reasons than because it is in pain. Crying is a protective reflex. A baby cries in the first instance because by so doing it benefits itself—for example, by expanding the lungs, attracting attention, or obtaining oxygen. The cry, however, may soon become a habit, and may continue long after it has ceased to confer any advantage. The causes of abdominal pain in infants in the approximate order of frequency are as follows: (1) Dysperistalsis of the intestines, including enterospasm caused by irritation, obstruction or nervous incoordination. (2) Disturbances of the motor functions of the stomach, including pyloric spasm, hour-glass contraction, spasm of the cardiac sphincter from wind, food, or other causes. (3) Incoordination of the motor functions of the bladder, spasm of the sphincter vesicæ, etc. (4) Referred pain from the thoracic cavity, pneumonia, pleurisy, empyema, etc. (5) Renal colic. (6) Spinal caries and osteomelitis. (7) Peritonitis, appendicitis, etc. Dysperistalsis or incoordination of the motor functions of the intestine, and chiefly of the colon or rectum, is undoubtedly the commonest cause of pain in infants. Indeed, in infants under six months of age it is a more frequent cause of pain than all other causes put together. As regards the treatment of cases of abdominal pain due to dysperistalsis or enterospasm: excluding all those cases which have an organic basis, they may well be divided into the two classes—acute and chronic. In acute cases the chief desideratum is to relieve the spasm and keep the bowel at rest until the exciting cause has been removed. To effect these purposes there is probably no better treatment than the old-fashioned remedies, castor oil and opium. Small and repeated doses of paregoric during which one can watch the effect, are much safer than the comparatively large dose. One drop given every hour to an infant three months old is not likely to lead to much trouble. Brandy is always a useful antispasmodic, and may be given in 10 to 15 drop doses to an infant of the same age. All food should be suspended until the symptoms have subsided. In the chronic cases there is a vicious cycle of events; the nervous system is made irritable and explosive by the constant sensory impressions which reach it, and the dysperistalsis is encouraged by this very irritability of the nervous centers. It is important, therefore, to dull the excitability of the nerve cells by a nerve sedative such as bromide or opium, while the intestine should, of course, be relieved of all unduly powerful stimuli. The adjustment of the food is naturally one of the factors on which success most depends; cow's milk is a powerful stimulus, especially in the unaltered state; completely peptonized it is less stimulating. Veal broth, whey, or even condensed milk, often help one to tide over temporary difficulties. The most valuable drug in all these cases of irritability of the bowel is petroleum, and this best in the form of an emulsion. Petroleum soothes the bowel; it lubricates its surfaces, and it seems in some way to check decomposition.

4. **Extradural Abscess at the Apex of the Petrous Bone.**—H. F. Tod states that an extradural abscess is the most frequent complication of acute inflammation of the mastoid process, being due to direct extension of the infective process through the bone to the outer surface of the dura mater, and is almost invariably found in the region of the tegmen tympani or of the lateral sinus, the latter being most frequent. In this particular instance the situation of the abscess at the inner part of the anterior surface of the petrous bone is exceedingly rare. The author reports a case in detail. Failure to discover such an abscess invariably leads to death from meningitis, usually from rupture of the abscess through the dura mater into the subdural and subarachnoid spaces on the posterior intracranial fossa; and necropsies proving this can no doubt be recalled by the majority of those who have had an extensive experience in aural surgery.

5. **Pneumococcal Abscess of the Lung in Children.**—L. E. Barrington-Ward points out that three varieties of acute abscess of the lung are met with in children. There is the abscess which arises from the presence of a foreign body in the bronchus; these are the multiple abscesses often following bronchopneumonia and debilitating illnesses, which abscesses are found scattered throughout the lung, are due to a variety of organisms and are not

amenable to surgical interference; and the single abscess due to the pneumococcus with or without a preceding lobar pneumonia. Barrington-Ward concludes that pneumococcal abscess formation is a possible mode of termination of a lobar pneumonia. The origin of this type of abscess appears to be in a patch of pneumonia, which instead of resolving after consolidation becomes the seat of pus formation. In fact, the pneumococcus takes on an action which is common to it in other parts of the body, but is rare in the lung itself. Possibly the age and resistance have a bearing on this point. Guinon describes the case of a boy of 4 who succumbed to a pneumococcal abscess of the lung not recognized before necropsy, and suggests the name of "hépatisation grise suppurée" for the process.

7. **The Use of Sugar in Heart Disease.**—S. E. Denyer states that physiologists have experimentally proved the nutritive value of sugar with reference to heart muscle. It has been established clinically that sugar undoubtedly gives good results in some forms of heart disease. In other forms no benefit has been observed from its use. Cases with edema, cases with anginal pain, and cases in which cardiac disease is secondary to renal disease do not seem to be improved by it. In a case of general paralysis of the insane, in which the pulse was failing, the author tried sugar, but it had no effect.

### Münchener medizinische Wochenschrift.

*April* 8, 1913.

**Acromegaly Following Female Castration.**—Goldstein relates the following case: At the age of 38 the uterus and adnexa were extirpated for multiple myoma. Menses at once ceased. The menstrual history had been one of continuous dysmenorrhea. Within a year after castration the woman's bones, which had always been thicker than those of her sisters and brothers, exhibited distinct enlargement, and this increase in size has continued slowly for nine years. Patient wears shoes and gloves two sizes larger than formerly. The chin, cheek bones and superciliary ridges have become more prominent. She perspires strongly and chills readily. She has rheumatoid and neuralgiform pains, marked vertigo, palpitation, polyuria, diminished sight and hearing. An *x*-ray picture of the skull shows no anomaly in the pituitary region, the hypophyseal recess being small rather than large. The forearm and leg are relatively longer and thicker than the upper arm and thigh. That the acromegaly was due directly to castration is evident; for according to authorities in one type of female castrates the bones become elongated. The patient had already present the anlage for acromegaly as seen in the abnormal thickness of some of her bones. Some unknown factor was evidently required in this case, however, for the author is unable to discover others like his own. The small size of the hypophysis appears to show that this gland was not primarily at fault. The tendency in childhood to excessive growth of bones does not speak for an acromegalic dystrophy, but rather for the closely related condition gigantism.

**Lecithin and Cholin as Antituberculous Remedies.**—According to Mehler and Ascher it has been known for some years that lecithin, as well as some of its constituents (cholin, glycerophosphoric acid) has a certain degree of bacteriolytic power. The authors, working in this direction, have found that certain cholin salts have little of this quality in vitro, but in certain combinations cholin is split off in vivo and may exert bacteriotropic and bacteriolytic properties. The proof of this is seen in the fact that certain cholin salts can determine a typical tuberculin reaction in the florid tuberculosis. It is not yet claimed that this property of the salt will make it an actual addition to our chemotherapeutic armamentarium. The action is by no means specific for tuberculosis, for cholin acts to some extent on bacteria in general. In the future we shall have a series of these substances to use as synergists. In addition to the tuberculins and lecithin constituents some of the heavy metals may be enumerated. Combinations of lecithin with copper, gold, etc., have been used for some time as chemotherapeutic remedies. The authors have caused to be placed on the market an unknown cholin salt with a proprietary name for those who wish to test the value of this class of substances.

### Deutsche medizinische Wochenschrift.

*April* 3, 1913.

**Functions of the Cerebellum.**—Edinger states that if the following up of the spinocerebellar paths brings us to the supposition that the cerebellum was originally intended to maintain the statotonus, another supposition is permissible, as the consequence of tracing the posterior columns of the cord by way of the thalamus, cerebral cortex, and pons into the cerebellar hemispheres, to wit, that the latter are stimulated by the impressions of the muscle position sense. Something is thereby added to the cerebellar functions of the inferior vertebrates in regard to the motor apparatus; and the sensory disturbances in cerebellar affections and the ataxia which follows extirpation of the cerebellum have further light shed upon their mechanisms. Clinically we may anticipate that atony and variations of movement are to be referred principally to the vermis, sensory disturbances to affections of the hemispheres expressed as true ataxia, the latter being something besides mere muscular weakness. The clinic will also indicate the distinctions between interruption or stimulation of the paths in the cerebrum, pons and cerebellar hemispheres. Affections of the latter may be simulated by cerebral affections and in the future one should be better able to explain how this comes about. What we most need at present are new investigations as to sensation, especially as concerns space orientation. The author supports the recent conclusions of Anton and of Kleist, that the symptom akinesia—slow execution of all movements as if inhibited—should be referred to the pons, which also may have to do with adiadochokinesis and asynergy.

**Eye Studies in German East Africa.**—Krusius states that he began his study of African eye diseases in Egypt, starting at Cairo and going up the Nile to the confines of Soudan. Throughout this region he found the same conditions, so that he was moved to follow them up with a possible discovery of an original focus. As he could go no further up the Nile he traveled by caravan to the Red Sea and then down the coast, where he took ship for German East Africa, finding everywhere the same conditions, which, however, seemed to attack principally the nomad element and to a much less extent the stationary black residents. In general there was a surprising agreement between the eye affections here and those of upper and lower Egypt. The percentage of those involved was a shockingly high one, also agreeing with Egyptian incidence. Smallpox blindness was but little in evidence, for the community has been well vaccinated. More common were the effects of acute purulent ophthalmia—leucoma, phthisis bulbi, etc.—which affects by preference the very young. Gonorrhea could be excluded in this connection. The vast majority of cases found were examples of trachoma and its sequelæ. As far as can be learned this affection has been endemic for centuries. The author finds nothing to justify a belief that this trachoma originated in the far South, because the negro of this locality has been largely exempt. The nomadic tribes studied, on the other hand, have reached this locality from more northerly regions. They are presumably of Semitic or Coptic origin and it is rational to suppose that they have carried the disease southward.

# Insurance Medicine.

## SUGGESTIONS TO MEDICAL EXAMINERS

BY THE INSURANCE EDITOR.

ELEMENTARY PRINCIPLES OF LIFE INSURANCE.

*The Loading:* The net premiums only have been referred to, heretofore, as the question of creating an insurance fund devoted solely to the purpose of paying death claims was given first consideration. Furthermore, simplicity was gained by excluding the matter of expenses in the discussion of that part of the subject. The expenses must be taken into account, however, before the gross premiums, the premiums which the policyholders pay, can be definitely determined.

It is imperative for the sake of unquestionable security that the companies be properly managed, and this can only be accomplished by men with special training and ability in the various branches as the business of life insurance is a most complicated one. The hypothetical company which has been useful for the purposes of illustration, could be terminated after meeting the requirements of the last contracts and the expenses of running such a company would be comparatively small. For practical use, however, it would be of little value and confined to a very small part of the community. As a matter of fact, a regular company is made up of a great number of groups similar to the hypothetical company which are being formed continuously and under one management. An actual company must be virile and permanent, —not an affair which will pass away in a few years. To inspire confidence and afford absolutely certain protection to the present and future generations, it must be conducted on as perfect lines as it is possible to attain and this cannot be accomplished without certain expenditures.

The chief item of the expenses is composed of the commissions for the procurement of new business. The cost of collecting the premiums and keeping the old policies in force must be charged up. Then come the items of rents, the salaries of the officers and the large clerical staff, the medical fees for examinations and miscellaneous expenses. Taxes levied by the various states constitute an important part of a company's expenses, and these are usually a percentage of the premium income.

Aside from expenses, provision must be made for all possible contingencies. While the assumptions as to mortality and interest in the computation of the premium have been made on a most conservative basis, it must be remembered that human judgment is fallible and mistakes possible. No one can foretell the contingencies of the future or the ordeals which life insurance companies may be subjected to by reason of wars, pestilence, adverse legislation, oppressive taxation, depreciation in securities, fall in the rate of interest, inefficient management, etc. With these in view, it is essential that the contract rate must always be more than adequate. When the rate charged is higher than necessary, it is a simple matter to return the excess in the form of a dividend, whereas if the rate is too low, there is no source from which a company can draw to make good the deficiency.

The allowance for expenses, taxes and contingencies is termed the loading, and is the difference between the gross premiums which appear in the rate books and the net premiums. The methods of loading vary. Sometimes it is a certain percentage of the net premium; at other times it is a more elastic plan composed of two parts, a constant sum (as $2.00 per $1,000 of insurance) for all ages and a percentage of the net premium.

The addition of loading is determined in an arbitrary manner and the amount varies slightly in the different companies according to the opinions of the respective actuaries, the companies having the privilege of fixing the rate as they see fit. Extravagant or reckless management which would call for an excessively heavy loading is, however, effectually prevented by the sharp competition which necessitates a standardization of the rates, and by the publicity of all the details of the business of every life insurance company as required by law in practically all the States.

---

**A Suggestion Towards the Prevention of Fraud in Life Assurance.**—At a meeting of the Life Assurance Medical Officers' Association, held in London, on May 1, 1912, Dr. Ogier Ward suggested that every local examiner, before launching into insurance work, should read carefully the volume of transactions of the Society he was addressing. The art of examination for insurance not being a natural gift, but acquired only after careful training and experience, the knowledge obtained from the transactions might avert many a blunder on the part of the ambitious examiner. Insurance companies should compel every doctor, qualifying for the position of examiner, to spend a day or two at the head office, in order to gain information about the methods used by the revising examiner, or medical director.

He referred to a previous paper, in which he had pointed out: (1) The need of special caution by examiners, when called upon to examine risks outside of their prescribed district, as many hidden or obscure cases might thus be passed. (2) The advisability on many grounds of avoiding the examination of one's own patients. (3) The importance of unvarying refusal to tell applicants (or agents as a rule) the result of the examination. (4) The importance of complete answers to every question. Thus, "Is he a Caucasian?" may appear unnecessary; but it is of import to a company issuing policies all over the world. (5) "Occupation?" (6) "Any connection with the liquor trade?" (7) "What is your daily consumption of alcoholic beverages? Have you ever taken them to excess?" Applicants, habitual drunkards, but "total abstainers" for the three months previous to applying, have, through these questions, been rejected. (8) "Have you ever had discharge from the ears?" This question, through its importance, has now become almost universal. (9) Urine.

Endless tricks, Ward says, have been played or attempted in this connection. Substitution is, of course, frequently attempted. Also, the use of drugs to get rid of functional albuminuria and traces of sugar. "Have you taken any drugs within the last fortnight?" would probably settle the drug question. Many insurance companies demand a second specimen of urine when the specific gravity of the first is below 1015 or above 1025, unless some comment is made in the report. Ward thinks this Association should compile a pamphlet, brief but comprehensive, for the benefit of the general practitioner, as the several books on life insurance, while excellent, are too large for ordinary work.

# Book Reviews.

The Principles and Practice of Medicine. Designed for the Use of Practitioners and Students of Medicine. By Sir William Osler, Bt., M.D., F.R.S., Fellow of the Royal College of Physicians, London; Regius Professor of Medicine, Oxford University; Honorary Professor of Medicine, Johns Hopkins University, Baltimore; formerly Professor of the Institute of Medicine, McGill University, Montreal, and Professor of Clinical Medicine in the University of Pennsylvania, Philadephia. Eighth Edition, largely rewritten and thoroughly revised, with the assistance of Thomas McCrae, M.D., Fellow of the Royal College of Physicians, London; Professor of Medicine, Jefferson Medical College, Philadelphia; formerly Associate Professor of Medicine, Johns Hopkins University. New York and London: D. Appleton & Company, 1912.

In comparing the third edition of "Osler" published in 1899 with the twelfth edition which has just appeared, one notes that the text of the latter fills practically the same number of pages as that of the former, 1150 and 1147 pages respectively, but that in the later edition there is a much more elaborate index, which fills 76 pages, instead of 30 pages, as in the earlier edition. It is also interesting to compare the tables of contents of the two editions. The infectious diseases are grouped in a different order and those of doubtful etiology are considered separately. The newer grouping indicates the important advances that have been made in this branch of medicine. These advances are notably seen in the recognition of the colon bacillus infections, in the discussion of pneumococcic infections, apart from the pneumonias, in the separate and more extensive treatment of the subject of the non-bacterial fungus infections, as the sporatrichoses, and of the protozoal infections, such as syphilis. There are new sections on Leishmaniasis, poliomyelitis, pellagra, disorders of metabolism, caisson disease, ochronosis, hemochromatosis, the disorders of the organs of internal secretion, and the diseases of the blood. In the section on typhoid fever one notes the important advance that has been made in the more liberal dietetic treatment of this disease. Although the latest edition of this popular textbook of medicine has been thoroughly revised, its original charm has not been impaired. There are still to be discerned in its pages those happy turns of expression which have become almost proverbial in the language of medicine. One serious defect of the earlier editions has been remedied in the last one, namely, in the somewhat more adequate presentation of the subject of treatment, though the conversion of the author from therapeutic nihilism to rational medicine is very gradual and by no means yet complete. The work still maintains its position among those in the front rank of the single volume textbooks on medicine.

The Surgical Clinics of John B. Murphy, M.D., at Mercy Hospital, Chicago. Volume I; Numbers V (October) and VI (December). Published bi-Monthly. Philadelphia and London: W. B. Saunders Company, 1912.

The interesting features noted in the past issues of this series are continued in the numbers herewith, and as the style, etc., has not varied further comment as to the general makeup of the book is unnecessary. Number V contains clinical reports of cases of renal calculus, cholecystitis, exophthalmic goiter, and a number of abdominal, cranial, and other surgical conditions. Although there is nothing particularly noteworthy in any of these cases the speaker has surrounded them with considerable interest by his well-known colloquial treatment of the same. As such, they are of undoubted value to many practitioners. In number VI of the volume there is interpolated a talk on carcinoma of the breast by Professor Bastianelli, whose work in this field is well known. Dr. Caan of Heidelberg likewise contributes an article on the treatment of malignant tumors with radioactive substances, in which he speaks of the good effects obtained with the same, which cannot be regarded, however, as an invariable cure. The inclusion of a case of salpingitis in Dr. Murphy's list of clinical lectures shows that he is not averse to invading the field of the gynecologist in his operating, but on the contrary that everything is fish which comes to the net of the "abdominal" surgeon. A number of excellent reports of bone cases, in which Dr. Murphy's abilities are undoubted, are also included in this number, which closes with a complete index of the entire volume. These books have met with a very favorable reception and will undoubtedly continue to be received with great interest by the many followers of this well-known Chicago surgeon.

Psychoanalysis: Its Theories and Practical Application. By A. A. Brill, Ph.B., M.D., Chief of the Neurological Department of the Bronx Hospital and Dispensary; Clinical Assistant in Psychiatry and Neurology at Columbia University Medical School; formerly Assistant Physician to the Central Islip State Hospital, and to the Clinic of Psychiatry, Zurich. Price $3.00 net. Philadelphia and London: W. B. Saunders Company, 1913.

The Freud theories have passed through a rather long evolution before reaching their present state. Freud himself has not yet given us a textbook presenting his conception in a systematic manner. Most of his writings have appeared fragmentarily in separate papers, subsequently united into volume form, in which even the German reader finds it difficult to follow him clearly; and this may be responsible for much of the criticism directed against Freud. Again, Freudian works thus far accessible to the English reader deal largely with his theories and less with their practical application. While in the present book a noteworthy feature is the many interesting and convincing analyses of cases drawn from the writer's large personal experience.

The first chapter deals with the theories of hysteria, obsessions, doubts and phobias and their relation to sex, dreams and psychopathological actions. The second chapter gives a full account of the rules of dream interpretation citing many very interesting examples. The third chapter deals with anxiety neuroses anxiety hysteria, and neurasthenia. The fourth treats of the compulsion neuroses, giving analyses of cases. The fifth chapter shows the application of psychanalysis to the psychoses as done in the clinic of psychiatry at Zurich, where Freud's theories were confirmed experimentally. This chapter also contains a lucid account of Jung's association experiments. The sixth chapter treats of the psychological factors of paranoia and belongs to Freud's later writing. The seventh chapter —the psychopathology of everyday life—is illustrated by very interesting and instructive examples, proving the theory of absolute psychic determinism. The eighth, ninth, tenth and eleventh chapters deal respectively with hysterical factors and dream states, the Œdipus complex, the only or favorite child, and anal eroticism and character, all of which abound in many novel and instructive facts. The last chapter is a thorough analysis of Freud's theory of wit in its relation to unconscious mental activities, to dreams, and to psychoneuroses.

Manual of Medicine. By A. S. Woodwark, M.D., M.R.C.P.; Junior Curator of St. Bartholomew's Hospital Museum; Physician to the Royal Waterloo Hospital and the Miller General Hospital for Southeast London; Late Casualty Physician, St. Bartholomew's Hospital, and Senior Resident Medical Officer, Royal Free Hospital. Price $3.75. Edinburgh, Glasgow and London: Henry Frowde and Hodder & Stoughton, 1912.

The purpose of this little book, as stated in the preface, is to supply a "vade mecum for the student clerking in the wards or out-patient department, and a convenient reference for the general practitioner." This book is unique in its succinct presentation of the subject matter, as the result of which a vast amount of material is gathered within its four hundred pages. The style is synoptic, which makes the book admirably adapted for quick reference, and particularly for purposes of review to one who is already familiar with the larger text-books on medicine.

Health and Longevity Through Rational Diet. Practical Hints in Regard to Food and the Usefulness or Harmful Effects of the Various Articles of Diet. By Arnold Lorand, Carlsbad. Price $2.50 net. Philadelphia: F. A. Davis Company, 1912.

In view of his large practical experience in the dietetic treatment of many disorders at Carlsbad and of his extensive traveling and observation, the author is peculiarly fitted to handle his subject. He has done this in a broad and comprehensive way, discussing the influence of food upon man, pointing out the effects of the various components of food upon the different organs of the body, the fundamental laws of rational feeding, the good and evil effects of various food substances, and the advantages and disadvantages of an exclusive vegetable or an excessive meat diet. In addition he has discussed subjects which have hitherto seldom been touched upon in scientific works, as, the manner in which various functions such as, intelligence, the sexual function, etc., can be activated through the diet. As Victor C. Vaughn, who has written the introduction to the American Edition on this work, points out, the book is remarkably free from the fads that render so many writings of this class harmful to the laity. It can be heartily recommended to all those who are responsible for the choice and preparation of food and may be read with profit by the physician, unless he has given more time than is often the case to the study of dietetics.

## REPORT OF TUESDAY AFTERNOON CLINICAL CONFERENCE OF THE NEUROLOGICAL INSTITUTE.

FIRST DIVISION—DR. JOSEPH COLLINS.

**Acute Degeneration of the Cauda Equina Simulating in Its Clinical Display New Growth in This Region.**—Dr. JOSEPH COLLINS after demonstrating a patient from whom a tumor of the cauda equina had been removed a year ago said that he wished to present a patient whose history and objective symptoms were absolutely parallel to those of the patient in whom a tumor had been successfully removed but in whom upon opening the lumbosacral spinal canal no indication of new growth was found. On the other hand a lesion of the tail was found to which as yet no descriptive name can be given. We refer to it here as an acute degeneration rather than inflammation or edematous state as it has no ocular appearance of either of these. The case could be taken as substantiation of the statement that tumor of the cauda equina, despite the fact that it causes a definite symptom complex, cannot be diagnosticated with confidence. There occurs an inflammatory or edematous state of the cauda equina, in some instances following

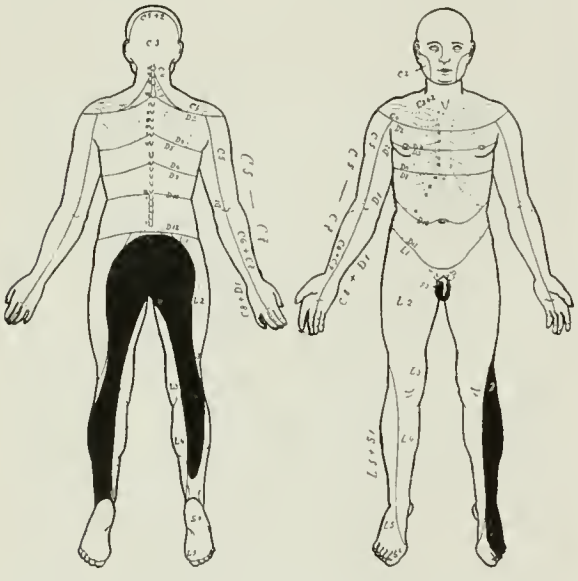

Fig. 1.—Areas of anesthesia to pin scratch.

trauma, in others occurring in the wake of infection, constituting caudal neuritis whose clinical features in the earlier career of the disease at least cannot be distinguished from caudal tumor. By its more benign course in some instances and by the eventuation in partial or complete recovery it finally differentiates itself.

The patient, a married clergyman, 46 years old, was able to discharge his pastoral duties up until November 3, 1912. His illness, however, dated back to January, 1910, possibly even longer than that. The important facts in his medical history seem to be:

(1) Lumbago off and on for the past eight years. (2) Six years ago, while ascending the Alps, slipped and fell several yards. Able to walk home, suffered acute pain at the tip of his spine. This passed away in a fortnight. (3) November, 1909, was lifting a heavy piece of furniture and strained himself. This was followed by considerable pain in his lower spinal region, which lasted with variable intensity for several weeks. (4) January, 1910, had a fall while skating, striking his back on the ice. Acute pain in his spine and down the right leg. Experienced a good deal of pain and difficulty in walking home. Pain in his spine off and on till April, 1910. (5) April, 1910, consulted a surgeon, who diagnosticated his case as a displacement of one of the lower vertebra, most likely caused by his frequently bending over his desk. Put on a brace to keep his spine in an erect position. He contracted pneumonia the following day, but made an uninterrupted recovery. (6) July, 1910, had not improved, so he discarded the brace and felt the better for having done so. (7) January or February, 1911, sudden attack of lumbago in small of back, a sharp pain went down his right leg. Tingling of the toes of both feet; left more than right. Was unable to raise himself on his toes because they felt too weak to support his weight. This passed away in a month's time. (8) November, 1911, attack of shingles on the right side. (9) 1912, spent part of the Spring in England, and was able to walk, cycle, and lead a normal life, free from pain or inconvenience. (10) August, 1912, sudden attack of "lumbago," followed by pain down the right leg to heel. Had to sit down frequently, which gave him relief for the time being. (11) October, 1912, consulted a surgeon, who took *x*-ray pictures with negative results. He made a diagnosis of periostitis, and applied the cautery and strapping to his spine. He did not improve under this treatment. (12) November 4, 1912, while bending over the washbasin, felt a sudden shaking and jerking sensation in

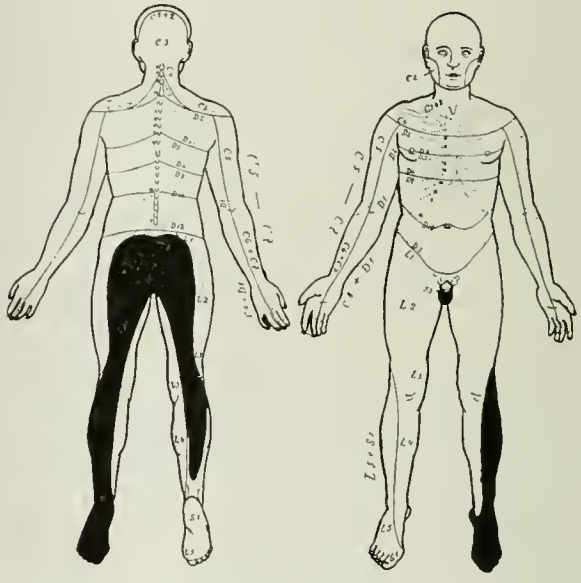

Fig. 2.—Areas of touch (brush) anesthesia. The areas of temperature anesthesia are of the same general contour, but 1 to 2 cm. wider all around

his lower spinal region, followed by intense desire to go to stool. He seemed to collapse, and found he was paralyzed from his waist down. Was dragged into bed by his wife. Since this time he has been catheterized regularly, though he feels normal sensation in his bladder and rectum. Has never had any incontinence. Though the sensations are blunted, he still feels the contact of the bed clothes and other objects to his feet, legs, etc.

His complaint on entrance to the Neurological Institute, February 1, 1913, was of: (*a*) Inability to stand or walk, (*b*) inability to urinate, (*c*) pain referred to the glans penis, and described as if the glans were thrust into boiling water, (*d*) numbness of the toes, (*e*) insomnia and great mental depression.

Physical examination reveals that the skin over the peroneal surface of the legs is thin and glossy, and that there is atrophy of both thighs and calves, more pronounced on the left side. He can flex the thighs slowly upon the abdomen to a limited extent, and he can flex the knees to a slight extent. He has very slight motion at the ankle joints and the feet are in position of double foot drop. He has very little capacity to flex or extend the toes. The tendon jerks of the lower extremities are unelicitable, nor could any plantar response be obtained.

The cremasteric, abdominal, and epigastric reflexes are normal. The sensory disturbances were profound and are depicted by the accompanying charts (Figs. 1 and 2). There is pronounced arcus senilis which has developed since November, 1912. The pulse is rapid, of low tension, and dichrotic. The systolic blood pressure 115, the diastolic 70. The spinal fluid, which was straw color, contained an excess of globulin; but no other abnormality.

In view of the negative *x*-ray findings, the history of the development of the paralysis and of the bladder trouble, and particularly the attacks of pain that he had had taken in conjunction with the objective sensory disturbances, a diagnosis of tumor pressing upon the cauda equina was made and operation was recommended.

Dr. Charles E. Elsberg, the surgeon to the institute, did a laminectomy on February 4, 1913. No tumor was found. The tail was lusterless, of faint bluish tinge, instead of white and glistening. It had the appearance as if it had been treated with some caustic chemical. The patient made a prompt recovery from the operation, since when his condition has been unchanged, save that the bladder symptoms are not so distressing. What the outcome of the case will be time only will determine. That it may eventuate in recovery, however, is probable. The nature of the lesion in such cases must be determined by further study. It is not at all unlikely that such cases are not rare.

The pronounced arcus senilis and the low tension dicrotic pulse, such as we encounter in fever like typhoid, suggests that we are dealing with some process dependent upon a circulatory toxin. But the condition is not due to bacterial invasion with toxic products, as there is an absence of fever and the leucocytes are not called out, nor are there any polymorphonuclear cells of infectious type. It must therefore be a metabolic change, either a failure in secretion or excretion. Then, too, the appearance of the cauda equina would suggest some such process. This is further borne out by the excess of globulin and the straw color of the spinal fluid, which in the absence of a secreting tumor is nothing more than transudation of the blood serum, possibly due to irritation or diseased vessel walls.

SECOND DIVISION—DR. PETERSON.

**Myasthenia Gravis.**—Dr. Foster Kennedy presented C. K., female, age 17, who was referred to the hospital complaining of double vision and dropped eyelids. Her previous health had always been good. Seven healthy children, she being the sixth child. For five months before the onset of the present condition patient had been employed in painting with water colors.

In the latter part of October, 1912, patient had severe frontal headache, no vomiting, no shivering, no feeling of fever. A week later, on a Wednesday night, the left eyelid felt heavy, and she found that she was unable to keep it but half open. The right eyelid was then normal. No diplopia. She felt well.

After a week's time the left eyelid slightly improved, but the right eyelid became heavy, and in a few days was in a condition similar to that of the left side. She had acute double vision, with involvement of the right eye. The relationship of the images has been very changeable since then. Condition of her eyelids has fluctuated much; sometimes there was little or no ptosis present; at others ptosis, particularly of the left eyelid, is complete.

No history of any other forms of muscular weakness. Blood count and blood Wassermann both failed to show anything abnormal.

On examination the optic discs are normal; there is complete immobility of the eyeballs for conjugate movements upward. The left eye has limited downward movement. This is true, but in a lesser degree, of the right eye, also. Slight weakness of outward movement in the left eye. Diplopia not found on examination. The right

Fig. 3.—Showing complete ptosis of the left eye, semi-ptosis of the right eye, elevation of eyebrows, and enforced attitude of the head.

pupil is consistently larger than the left, but both pupils show normally brisk reactions. There is a high degree of left-sided ptosis; a slight degree of ptosis in the right eyelid; well marked overaction of the frontalis muscle. There is no weakness, no wasting elsewhere in the body; there is no sensory change, and the reflexes are all normal.

Diagnosis in this case is somewhat obscure, but it was pointed out that the onset was subacute and differed therein from the paralysis of the eyeballs associated with Wernicke's name. Beyond headache, the onset was unaccompanied by any constitutional disorder. The variability of the condition since October has militated against a

Fig. 4.—Showing range of downward movement of the eyeballs.

neurogenic causation being probable, and has made almost certain that the proper diagnosis is myasthenia gravis. The one factor in this case difficult to explain on this hypothesis is the persistent inequality of the pupils.

THIRD DIVISION—DR. PEARCE BAILEY.

**A Case of Tumor of the Right Temporal Lobe.**—Dr. Louis Casamajor, in presenting this case, said: The right temporosphenoidal lobe of the brain, while relatively "silent" so far as known physiological function is concerned, nevertheless has a symptomatology of its own by means of which localization is possible. The sensations of smell and taste have bilateral cortical centers situated in the tips of the temporosphenoidal lobes, the irritation of which causes hallucinatory outbursts of smell and taste sensations usually of unpleasant nature. From the observations of Alzheimer and others on the sclerosis of the cornu ammonis in so-called idiopathic epilepsy one may expect epileptiform seizures in temporal lobe tumors, and this is usually the case. Again, the close proximity of the tip of the temporal lobe to the optic tract and the thalamus add to the picture symptoms of involvement of tongue became thick and he had difficulty in pronouncing words. In July, 1912, he again had an unconscious spell, in which he fell while walking in the street. He was picked up and taken home. He felt very weak after this, but the weakness of the left arm and leg was not increased. One month later a similar attack occurred, with similar results. Since this he has become suddenly weak while walking in the street, on three or four occasions and fell without losing consciousness. For a couple of months before admission he frequently noticed a bad taste and smell in his mouth, as of decaying meat, lasting from five minutes to a half hour.

Physical examination on admission showed normal pupils which were equal in size. Normal ocular movements. Vision 20/30 in each eye. A complete left homonymous hemianopsia for small objects (see Fig. 5), while the vision for larger objects was good in the left field, at times the hemianopsia was complete. There was a papilloedema of 3 to 4 diopters in either eye. The facial muscles were weaker on the left side, which weakness was more noticeable on laughing than on voluntary movement. There was no perceptible weakness of the left

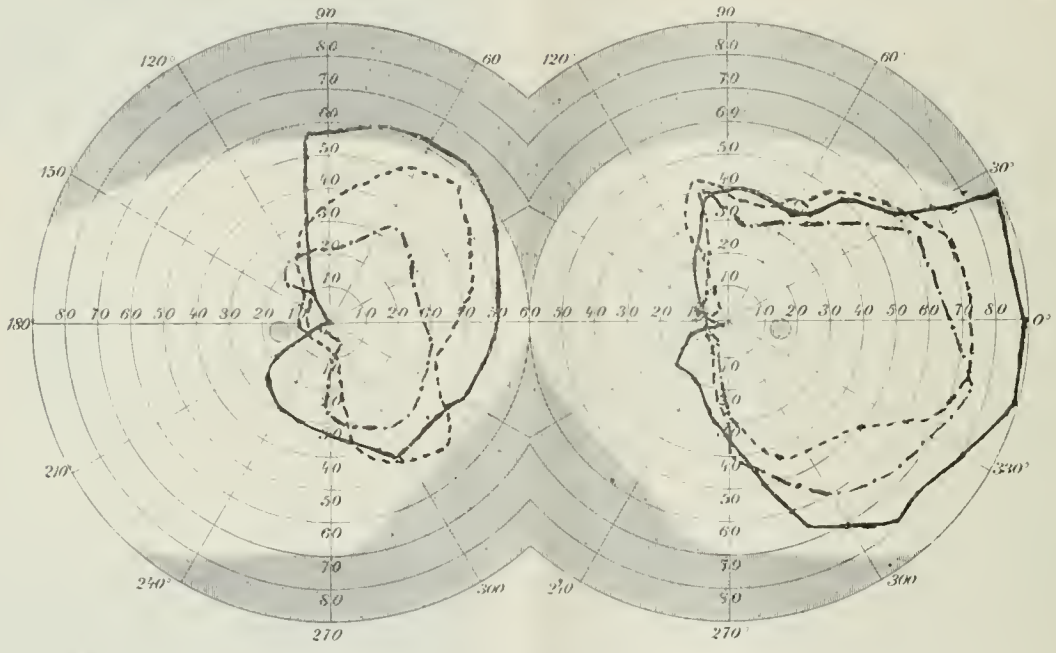

Fig. 5.—Visual fields in Dr. Casamajoris case; straight line, perception of white; dotted line, of red; broken line, of blue.

these structures, *i.e.* contralateral homonymous hemianopsia from optic tract involvement, and sensory disturbances, etc., from that of the thalamus. The case reported here brings out well these points.

A. E., 37 years of age, metal worker, born in Sweden, was admitted to the Third Division on December 17, 1912, complaining of headache, weakness of the left arm and leg, intermittent blindness of left eye (?) (hemianopsia), and occasional attacks of unconsciousness.

His family history was negative, as was that of his early life. Luetic infection was denied. His present trouble dated from April, 1912. At this time had his first attack of unconsciousness. He was straining at stool when his head turned suddenly to the right, his eyes felt peculiar, he bit his tongue and fell to the floor unconscious. After forty-five minutes consciousness returned, and he found that his left arm and leg were paralyzed. After two weeks his left hemiplegia receded to such an extent that he was able to resume his work. After this he had very frequent and severe headaches. At times his left visual fields would be blurred for a few minutes. Occasionally he became confused for a few minutes and did not know where he was. Frequently his arm and leg, but the deep reflexes on this side were increased and the superficial reflexes diminished. There was no clonus and the Babinski on the left side was doubtful. Both arms and legs showed an intention tremor which was most marked on the left side. Careful sensory examination demonstrated hypesthesia and hypalgesia on the entire left half of the body.

The Wassermann reaction was negative, the urine normal. A diagnosis of tumor of the right temporosphenoidal lobe was made upon the following points: (1) Right temporosphenoidal lobe signs: (*a*) Intermittent attacks of foul odor and taste in the mouth as of decaying meat; (*b*) general epileptiform attacks and momentary periods of confusion. (2) Neighborhood pressure signs: (*A*) Right optic tract left homonymous hemianopsia for small test objects, fluctuating in character; (*B*) right optic thalamus, (*a*) hypesthesia and hypalgesia; (*b*) weakness of the left face on smiling and laughing. (3) Tumor signs: (*a*) Optic neuritis of 3 to 4 diopters swelling, (*b*) severe constant headache.

On December 23, 1912, an exploratory craniotomy was performed by Dr. A. S. Taylor and the right temporosphenoidal lobe exposed. There was a considerable pres-

sure. By incising deep into the tip of the lobe a soft tumor mass about one inch in diameter was exposed and removed, which on microscopical examination was found to be glioma.

Recovery from the operation uneventful.

## MEDICAL SOCIETY OF THE STATE OF NEW YORK.

(Special Report to the MEDICAL RECORD.)

(*Continued from page* 826.)

SECTION ON MEDICINE.

*Wednesday, April 30—Second Day.*

**Election of Officers.**—*Chairman,* Dr. CHARLES STOVER of Amsterdam; *Secretary,* Dr. George Reese Satterlee of New York.

**Typholalbuminuria.**—Dr. HEINRICH STERN of New York read this paper. He said that in alimentary albuminuria in general and typhloalbuminuria in particular there was one main channel, and in uncomplicated cases it was probably the only one, through which the protein was conveyed to the urine. It was the route taken by the chyle in the condition known as chyluria, and a similar, if not the same one, often followed by the colon bacillus invading the urinary tract when the infection was not of the ascending type. There existed no, or but an inconsiderable, globulin excretion in the albuminurias of intestinal origin. This factor at once precluded the blood as the protein carrier in these types of albuminuria. Typholalbuminuria was an alimentary albuminuria proceeding from the cecum. It was probably the most frequent of all the intestinal albuminurias. It was irregularly intermittent, that was, it disappeared and returned at irregular intervals, independent of the protein intake just preceding it. It might be continuous for several days and again be absent for weeks at a time. It invariably occurred in persons with habitual constipation. Its pathogenic factors were cecal atony, rapid absorption of liquid from the cecum, the resulting extreme dryness of the feces, and coprostasis. One could not speak of typholalbuminuria unless the cecum appeared to be at the bottom of the albuminuric phenomenon. The structurally or functionally defective cecum was bound to disturb the intraabdominal equilibrium in general and the visceral lymphatics in particular. The lymphatics, including those of the cecum and its mesocolon, became readily overfilled, and a lymph stasis might ensue. The escape of some of the contents of the engorged lymph channels through newly formed lymph varices near the surface of the lining epithelium of the urinary tract was but a natural consequence. The occurrence of typholalbuminuria did not depend more upon the amount of protein ingested at any one time than on the interrupted draining of the lymph stream into the venous system.

Dr. L. F. BISHOP of New York said that the paper had some very suggestive ideas. The connection between the lymph channels and the urinary tract was an important idea in connection with the remarkably new knowledge of the process of protein digestion and absorption. Dr. Van Slyck of the Rockefeller Institute announced in his lecture before the Harvey Society that the amino-acids were broken up in the intestines and absorbed into the blood but almost immediately were taken up by the tissues. For this reason they could only be found in the blood for a short time after digestion. Thus they had the astonishing picture of a meal of albuminous food being almost immediately deposited in the cells of the body. From the tissues this crude material must be reabsorbed into the blood for gradual disposition by the kidneys, liver, etc. It was easy to see that this must bring about a condition by which the lymphatics could well become the source of albuminuria rather than the blood-vessels.

**Cardiospasm: What Is It? What It Seems to Be.**—Dr. ANTHONY BASSLER of New York read this paper. Cardiospasm, which had always been described as a spasm of the cardiac orifice of the stomach was shown to be epicardial in almost every instance. The lower extremity of the esophagus, or cardiac orifice of the stomach, had no, or only a faintly developed, sphincter. Since it had not been proven that cardiospasm was not what its name implied, he made observations in the hope of elucidating this point. As a result of the dissection of five cadavera, he pointed out among other things that at the esophageal opening of the diaphragm the normal gullet was wider than above it, and that below the opening it was funnel shaped; that there was a length of esophagus in the abdomen about the distance of the height of one vertebra running from the esophagus opening of the diaphragm to the cardiac orifice; that there was a bulb or dilatation in the gullet above the diaphragm due to the anatomy of the esophageal opening; that a status of tonus existed in the fibers of the crura which tended to press upon the gullet; this was not demonstrable during anesthesia or at death; that the barrier to foods from the stomach into the esophagus was brought about by the pressure of the left lobe of the liver, folds of mucous membrane extending into the stomach from the gullet, and the resisting opening in the diaphragm and not by any arrangements of the circular or oblique fibers in the esophagus or cardiac orifice of the stomach; that the study of the arrangement of the fibers proved that when they were spasmed the logical result would be an opening of the tube or orifice rather than a stricture; that the anatomy of the muscular fibers of the crura surrounding the esophageal opening was such that by tonus of them they contracted upon the gullet drawing the central tendon of the diaphragm sharply into the esophagus; that the operative literature against this assumption was meager; that his *x*-ray observation in seven cases of cardiospasm suggested that the stricturing factor was the esophageal opening of the diaphragm, and not the gullet itself; that when these cases were dilated mechanically the effects were produced by stretching the esophageal opening, and that if the interpretation of his studies were correct it seemed warranted to consider an operative procedure for intractable cases which had to do with the division of the crura either at their insertions or the bisection of the inner portions of both at the back of the gullet or some portion of the esophageal opening.

**Cooperation of State Medical Societies in Public Health Education.**—Dr. ELEONORA S. EVERHARD of Dayton, Ohio, read this paper. She said that through the work of Pasteur came to the medical profession the beginning of that knowledge by means of which all infections might be stamped out. Yet in the year 1913 1,500,000 persons would die of preventable disease. This loss would be due in part to ignorance of the victims, in part to willful disregard for laws of health, and in large part of the defencelessness of the innocent in the presence of ignorance and willfulness. For the protection of the health of the community statutory regulations were wise and just; but laws were enacted only at popular demand, and if enacted without the support of public opinion they failed of enforcement. General education of the public would insure better health regulations. It was neither possible nor desirable to make of each individual his own sanitarian. Help him to see the need for sanitation and to quicken an appreciation of training in the officer who was to be the custodian of the common health. Of what avail was legislation if the local health officer was lacking in either time, knowledge, or inclination to enforce the law. In 1909 the women physician members of the American Medical Association were requested to take the initiative individually in their respective associations in the organization of educational committees to act through women's clubs, mothers' associations, and other similar bodies, for the dissemination of accurate information touching the nature and prevention of disease and to elect from among their number a committee to take charge of the same. At the same time, all county, district, and other local medical societies were requested to hold annually one or more open meetings to which the public should be invited, and which should be devoted to the discussion of the same subject and to the general hygienic welfare of the people. Before the end of the second year work was organized in 45 states, 238 counties, Alaska, the Philippines, Hawaii, and the Canal Zone. The last annual report showed audiences aggregating little less than 400,000. The report for this year would show a material increase over those figures. The Committee of the American Medical Association found its most appropriate field in coordinating the educational work of the several states and making known to all those methods found effective in any. To the State Medical Society remained the privilege of cooperating with that committee by assisting the county societies and through them encouraging the individual physicians, thus guarding health interests within the State.

Dr. JOHN A. WITHERSPOON of Nashville, Tenn., did not believe that any more important subject could be brought before such a body of medical men, and he called attention to the fact that the American Medical Association had spent a large sum of money in educating the people in these matters.

**The Industrial Disease-Reporting Law.**—LEONARD W. HATCH, Ph.D., State Statistician, New York State Department of Labor, read this paper. He said that compulsory reporting by physicians of certain industrial diseases was inaugurated in New York State, September 1,

1911. It was the purpose of his paper to set forth the fundamental reasons of such compulsory reporting of industrial diseases, and to illustrate from actual experience how this purpose was to be worked out in practice; also to emphasize the necessity for certain details required in reports, and to suggest the larger opportunities beyond mere legal requirements which lay at the physician's door in this field. With reference to the general purpose of compulsory reporting of industrial diseases by physicians, the New York law did not represent something novel and untried. On the contrary, if one looked to the experience of other countries, it would be found that such registration represented only settled practice. Thus, in Great Britain reporting of industrial diseases, precisely like that in New York, had been required for eighteen years. In fact, the New York reporting act copied the British law directly. In the same year that the New York law was passed (1911) five other states (California, Connecticut, Illinois, Michigan, and Wisconsin) took the same step. Last year two more states (Maryland and New Jersey) passed similar acts, making in all seven states which had adopted the system. It was probably safe to say that it was only a question of time before such registration of industrial disease would be generally required in this country. But there was better reason for such a law than its mere existence elsewhere. In endeavoring to make this clear he asked them to consider three points: First, that the law has a very practical end in view which was of great importance as a matter of public welfare and social justice; second, that the method of reaching this end commended itself as scientific, and third, that no other plan could as well effect the purpose. The act of 1911 made only six diseases—poisoning by lead, phosphorus, arsenic, or mercury, anthrax, and caisson disease—reportable. By an amendment passed this year two others—poisoning by wood alcohol, or brass—were added. But outside of these eight there was a long list of poisons and diseases whose causes were to be found in circumstances of occupation. In Great Britain, where work in this field was further advanced, more than a score of industrial diseases had been so clearly identified as due to hazards of occupation that they had been included under the workman's compensation act which insured to workers automatic compensation for injuries arising from the nature of their employment. It was this broad pioneer field which was here pointed out to the physicians of New York State as one needing investigation in order that the present rising demand for legislation along these lines might be guided by accurate knowledge of the facts, and as one which the physician by reason of his professional knowledge was peculiarly fitted to study.

**Experience with Neosalvarsan at the Harlem Hospital.**—Dr. Howard Fox of New York read this paper, which gave the results of his personal experience with 175 tubes of the new remedy received from Professor Ehrlich. The experimental work was done in the out-patient department of the Harlem Hospital, the patients being allowed to go home immediately after treatment. Of the 56 patients that were treated, 45 were given intravenous injections. One of these received two injections, 17 received three, and 27 received four, the treatment being given, so far as was possible, every other day. No other antisyphilitic remedy was used. The cases included various forms of cutaneous syphilis, syphilis of the mucous membranes, of the eye and bone; also a few cases of latent syphilis, and one of tabes. Muscular syphilides disappeared as a rule within a week, and most of the papular syphilides in from two to four weeks. Very gratifying results were obtained in cases of the nodular syphilide, while they varied in cases of gummata. The mucous membrane lesions showed the same tendency to rapid disappearance that was so characteristic of salvarsan injections. One case of condylomata, however, did not clear up until the end of five weeks, although three intravenous injections had been given. One case of iridocyclitis cleared up in three weeks; in another patient an iritis appeared during the course of treatment. A most gratifying result occurred in a case of marginal keratitis. The redness and photophobia disappeared on the second day after the injection, and on the third day the patient could read. There was no improvement in a child with interstitial keratitis; at the end of one month the second eye became involved. No change occurred in two cases of atrophy of the optic nerve, or in a case with paralysis of the superior rectus muscle with ptosis. The result of treatment in several cases of bone syphilis was very satisfactory. One patient had suffered from osteoperiostitis of the tibia for two years; this caused a great deal of pain and difficulty in walking. After a single intramuscular injection the pain disappeared in twenty-four hours, and at the end of a month the patient could walk without difficulty. The improvement was also shown by accompanying radiograms. Another patient with periostitis of the ankle and knee was given three injections. Although the knee had been stiff for six months, it became perfectly normal on the day after the second injection. In a case of osteoperiostitis of the femur practically no change except a lessening of the night pains occurred. One case of tabes dorsalis showed an improvement in gait and general strength. The Wassermann tests were made, as far as possible, at monthly intervals. Of 36 cases treated by three to four intravenous injections, and followed serologically for an average of over five months, one became negative and remained so for four months; two became negative and two almost negative, but later relapsed and became partially positive. A lessening of the strength of the reaction took place in 16 cases, while in 15 cases there was no change. In giving the intravenous injection it was not possible to obtain water that was absolutely freshly distilled. It was possibly due to this fact that chills or chilly sensations were noted after 27 injections, nausea after 30 injections, as well as other symptoms, none of which, however, were severe enough to prevent regularity of attendance at the clinic and return for further treatment. Among the general effects was a marked increase in the appetite and gain in weight. Eleven patients gained an average of 13 pounds. There was no disturbance in the menstrual function. The local effects of the intravenous injections varied from the formation of a tiny nodule to complete occlusion of the vein. This was as a rule so slight that four intravenous injections could be given in the same vein. The intramuscular method was tried in 11 cases; the results were excellent, although the pain and induration which followed more than counterbalanced the time and trouble of giving several intravenous injections. Dr. Fox offered the following conclusions: 1. Neosalvarsan was an excellent symptomatic remedy in the treatment of syphilis. 2. Its symptomatic action seemed to be slightly weaker than salvarsan when used in corresponding amounts. 3. Its serological action seemed to be considerably weaker than salvarsan when used in corresponding amounts. 4. It possessed a decided advantage over salvarsan in the greater ease and rapidity with which it could be prepared and injected intravenously. 5. Intravenous injections of neosalvarsan were much less disturbing to the veins than intravenous injections of salvarsan.

**Results of Salvarsan Therapy in Malignant Syphilis Precox, Syphilide of the Palms and Gumma of the Tongue.**—F. L. Ziegel of New York read this paper.

*Malignant Syphilis Precox.*—This was previously published in the Medical Record, 1909, Vol. LXXVI, p. 645, under the title: "Precocious Tertiary Syphilis: Report of a Case with Manifold Manifestations." The subsequent history of this case showed that in malignant syphilis with severe mucous membrane lesions which had been resistant to mercurial treatment, brilliant symptomatic results could be obtained with salvarsan. When in July, 1910, the patient passed temporarily out of observation, the Wassermann reaction was still strongly positive; contrary to advice he discontinued treatment because the patient was free from symptoms and lesions. When he returned in July, 1912, he was cachectic; there was profuse foul discharge from deep ulcerations, and broken-down gummata in the nares and pharynx. The Wassermann test was strongly positive. Neguchi's luetin test was positive, of a pustular type. After intravenous administration of 0.6 gm. of salvarsan the ulcerations healed rapidly, the discharge ceased, and the patient's weight increased from 112 to 130 pounds. The salvarsan treatment was repeated and followed by gray oil injections. In December, 1912, the patient was free from symptoms and lesions, but the Wassermann and luetin tests were still positive, and the patient was far from being regarded as cured of syphilis. Conclusion: Salvarsan caused rapid involution of severe syphilitic lesions, but did not effect a cure in malignant syphilis.

*Syphilide of the Palms.*—After three years of mouth treatment following primary luetic infection twelve years ago, a scaly eruption appeared on the palms which had been unsuccessfully treated with ointments when the patient first came under observation, three years ago. Twice apparent cure followed salicylate of mercury injections, but the Wassermann remained positive and the scaliness returned. Accordingly, 0.5 gm. of salvarsan in iodipin suspension was given intramuscularly and repeated in two weeks. Even before the second injection the palms had become soft and free from scales; up to date, during a period of two years of observation, there had been no recurrence. Nine days after the second injection the Wassermann was negative; twice subsequently it was nega-

tive. Luetin test negative in March, 1913. Seven months after marriage, nine years ago, there was a still-birth. Two years ago the wife's Wassermann was negative. She was now pregnant eight months, and the fetus was living. Conclusion: In scaling syphilide of the palms salvarsan was to be chosen as the specific in preference to mercury.

*Gumma of the Tongue.*—In 1905 a New York physician who failed to make it a rule to wear rubber gloves in his obstetric work noticed a pimple-like swelling on his right index finger which suppurated and refused to heal under surgical measures. Seven weeks later atypical secondary symptoms developed. First, with inunctions, and later with salicylate of mercury injections, the treatment was systematically kept up for four years, and was followed by negative Wassermann reactions from 1909 to 1911. In October, 1911, a protuberance of pin-head size was noticed on the dorsum of the tongue; the swelling increased in size to that of a pea in three days. Wassermann was now faintly positive. Intravenous injection of 0.6 gm. of salvarsan was followed by prompt regression of the tumor. One year later (in October, 1912) the Wassermann was negative, but neosalvarsan was given as a precautionary measure. In March, 1913, Wassermann and Noguchi's luetin tests were negative. Conclusion: Thorough mercurial treatment for four years after extragenital infection was followed in two years by a superficial lingual gumma which "melted away" after the administration of salvarsan.

**The Polygraph.**—Dr. George W. Ross of Toronto, presented this instrument. The MacKenzie ink-writing polygraph, and also his modification of the Dudgeon instrument were shown, and their manner of use explained. The great advantage of the polygraph was that it enabled one to record simultaneous tracings of two separate points in the cardiovascular system—for example, of the radial pulse and the jugulocarotid pulse, and to interpret the meaning of the various waves recorded. This was of especial importance with respect to the so-called venous pulse, inasmuch as certain of the waves gave valuable information concerning the vital activities of the right side of the heart—information that was commonly unobtainable except by instrumental means. The modern conception of heart anatomy and physiology was briefly reviewed, and the most important irregularities linked therewith. Next was considered the following arrhythmias: (1) Sinus, (2) Extra Systole (Premature Contraction), (3) Partial and Complete Heart Block, (4) Auricular Fibrillation, (5) Pulsus Alternans. The recognition of these by means of the polygraph was referred to and also their significance.

*Thursday, May 1—Third Day.*

**The Present Obligations of Physicians Regarding Syphilis as to Both Patients and the Public.**—Dr. F. Wood Ruggles of Rochester read this paper. He said that the advance in their knowledge regarding syphilis during the past eight years had been greater than that during the history of medicine. What had been learned previous to that time was purely empirical, at least, outside the pathology of the disease. Whether the disease existed at all prior to 1493 was problematic. It was certain at that time, at the siege of Naples, in both armies, it spread rapidly over Europe as a plague, and that until the whole world had been syphilized it had a high death rate. Soon after this outbreak it began to be recognized that mercury was the sovereign remedy against the disease, and this discovery was undoubtedly accidental, resulting from a trial of numerous remedies. In 1832 it was found that iodide of potassium was also a valuable remedy. A knowledge of these facts, however, had never been shared by the whole profession. Lereux and Metchnikoff succeeded in inoculating apes with the disease in 1905. Later Schaudin discovered a spirillum which he termed the spirocheta pallida, on account of its feeble staining properties. Physicians as a class were altruistic. They cheerfully sought that which no other profession or trade had ever done, to make their employment unnecessary by decreasing the number of diseases in the world through the teaching of prophylaxis, hygiene, sanitary methods, protesting against contaminated water supplies, etc. Yet the physician must live from his profession, without malice on his part; there was, however, a certain gratification when he was called to treat a chronic case which promised to be remunerative. Dr. Ruggles desired to arouse a new morality in regard to their attitude toward syphilis. In the presence of such a scourge, if they could do anything to lessen its consequences for the unfortunate victim, and diminish the chances of his communicating the same pestilence to others, they should forget all selfish, pecuniary motives, and do their utmost for a swift and sure eradication of the disease. It was his opinion that it was absolutely immoral for a physician to let a suspicious genital sore remain a single week without taking advantage of the darkfield method and making an early diagnosis, if possible. It should be borne in mind that the use of two or three injections of salvarsan obliterated the contagiousness of syphilis, as a rule. In his opinion, the most positive proofs of the superiority of salvarsan over mercury in the treatment of syphilis were the numerous cases of early reinfection and freedom from mucous plaques, with the rare occurrence of other secondaries. In his own practice, even after he had given up internal mercurial treatment, and was using only intramuscular, or inunction treatment, practically every case would present some mouth or throat lesions during the first year, some quite frequently, so that every week there were several mouths to be treated. At present, in spite of having a greatly increased number of syphilitic cases under treatment, he saw absolutely no mucous patches, except in patients sent for consultation who had not received salvarsan.

**Examination of the Exposed as a Factor in the Prevention and Relief of Tuberculosis.**—Dr. John H. Pryor of Buffalo said that the paramount importance of early diagnosis was to secure admission of patients to a sanatorium, and thus secure effective relief, education, and prevention at the opportune time. Only about 1 per cent. of consumptives in a given locality are sent to a sanatorium during the incipient stage, and about 99 per cent. were discovered too late or treated at home too long to secure benefits of modern knowledge and management. More and more patients were learning the truth and would ask why they were too advanced and the chance for proper relief and control lost. The excuse that patients did not consult a physician early enough was too often untrue. The new method of examining for pulmonary tuberculosis was not properly taught, and the text books were not up to date. Examination of the exposed did not apply alone to the danger of infection by long and close contact. They must remember that the same predisposing and contributing causes were at work, and they were often aggravated if the wage earner was afflicted. They knew that one case was often followed by another, and they should remember that they were dealing with a communicable disease. Watch for new developments in the home. The procedure of examining others exposed was so rational and necessary that it was strange it was not a routine practice. If not employed in a dispensary for tuberculosis the work was partial, faulty and worthy of criticism. The advanced case should lead to the incipient one, and others protected from somebody's blunder. The procedure was surrounded with difficulties now, and required much work for little or no remuneration, but obstacles would disappear if it became a recognized custom by the medical profession. At the Buffalo Tuberculosis Dispensary, where the method of examining the exposed was begun in 1907, the following report was presented where all the families were examined and one case existed: Pulmonary tuberculosis was found in one or more members of 248 families (35 per cent.). In 87 families 100 cases of pulmonary tuberculosis were discovered. In 113 families where other members were examined before and after the death of a consumptive other cases were found or reported in 40 per cent. It was a serious blunder to wait for symptoms, as many truly incipient cases were symptom-free, and might not appear for weeks after the diagnosis had been made. Hemoptysis was the exception, but it had occurred in 8 per cent. of 2,000 cases under observation. The examination of the exposed afforded the best opportunity to learn the art of early diagnosis. By the introduction of a rather new method, used principally by experts at present, there was little excuse for failure to recognize early cases. He referred to auscultation with cough. If this was not employed the area of disease might withhold its secret, and furthermore, the limits of invasion could not be clearly defined. Auscultation with cough was probably more valuable than all other means combined. The regions most frequently overlooked were over and at the edges of the sternum, and along the spine. The sternum was often not examined, and the free edges of the lungs not searched. A chart was added showing the comparative frequency of the initial location of invasion as revealed by physical signs.

**Auscultation of the Acromial Process: Its Importance in Apical Disease.**—Dr. Robert Abrahams of New York said that he had studied auscultation at the acromial ends of the clavicles for more than three years, and had come to the conclusion that this deserved a place in physical diagnosis. The method of procedure was very simple: the bell of the stethoscope was placed over the acromial end of the clavicle, and was adjusted in a way that there was perfect adaptation between instrument and bone. The

patient was told to breathe, to count, to whisper, to cough. Once in a while, in spite of best efforts, the adjustment could not be made, due either to instrumental or anatomical difficulties; then the procedure was a failure. When the apices were diseased the following was to be observed: (1) Right apex. In a case of a very early infiltration, auscultation at the ecromion process would yield an appreciable, prolonged expiratory sound, a louder spoken voice, and a slightly increased whispered sound. First-stage tuberculosis of the right apex would reveal tubular breathing, bronchophony, and whispered pectoriloquy, signs when found over lung tissue would indicate absolute consolidation. In other words, the usual acoustic phenomena which were, or should be, apparent in the first stage of tuberculosis of the apex, were greatly exaggerated, and made evident when the outer process of the right clavicle was auscultated. (2) Left apex. In incipient tuberculosis of the left apex, breathing conducted through the acromion end of the clavicle became pronounced bronchovesicular, and an increase in voice and whispered sound became marked and notable. The same changes were with difficulty perceived by auscultation of the apex itself. When the infiltration reached a fair degree of advancement, like unto the first stage, breathing heard at the acromial process assumed a tubular character; the voice changed into bronchophony, and the whispered sound sounded like pectoriloquy. The same signs, under the same condition of the apex, would be found over the apex, but not nearly so clear, demonstrable and pathognomic.

**Tuberculin Treatment.**—Dr. Edward R. Baldwin of Saranac Lake read this paper. He said it was evident that tuberculin treatment was often given ignorantly. The nature of tuberculin was important to understand. It was a poison to tuberculous individuals. All forms were similar in action when enough was given. If they produced no reactions, they were inert. The object of the treatment was either to reduce the hypersensitiveness or to stimulate the tuberculous tissue to heal by intermittent reactions. Cases for treatment should be built up in health and nutrition, and rested until acute symptoms subsided. All bad complications—intestinal, ulcerated larynx, fever of 100° F., or over, and weakness were contra-indications. Scrofulous cases were often favorable. Reactions were to be avoided; they might be local, focal, and general, with or without fever. The treatment was empirical, and an experiment in each patient. Rules about dosage were not hard and fast. Skin tests at the start formed some guide to dosage. Cures were not made by tuberculin alone, but might be assisted or retarded by it. It might produce much symptomatic good by lessening sensitiveness to itself, or it might aggravate the disease.

**The Incidence of Renal Involvement in Pulmonary Tuberculosis.**—Dr. Harry S. Bernstein read this paper and made the following summary: One hundred urines from cases of pulmonary tuberculosis were examined for the presence of the tubercle bacillus by guinea-pig inoculation. Ten (or 10 per cent.) produced tuberculosis in guinea pigs. Symptoms referable to the urinary tract were absent in each case. Control inoculation in five of the cases corroborated the first findings. Six of the positive urines were negative for albumin. Three urinary sediments contained pus cells. Cystoscopy of three cases revealed no pathological condition of the meati. In one case the urine from each kidney produced tuberculosis in guinea pigs. In two cases only one kidney was positive. The post-mortem records showed a percentage of 3.4 of kidney involvement in pulmonary tuberculosis.

Dr. Charles Stover of Amsterdam said that when they took into consideration the large number of hopeless cases of pulmonary tuberculosis which had continued after many months of treatment, and the fruitless search for health, the results that had been secured by the employment of artificial pneumothorax and with tuberculin were worthy of consideration. But this work should be done by the expert, and not attempted by the average physician. However, one must come to the conclusion that the successful treatment of this disease, tuberculosis, came finally to the question of sociality. He called attention to the good work done by the social workers, those who followed up patients at their homes and who were of great value in educating these sufferers, especially those in the incipient stage sufficient funds should be had to make this work successful. There should be complete organization, and they should take advantage of every State Aid Charities societies which existed in every town.

Dr. Baldwin emphasized the importance of getting at the early cases of tuberculosis. When an early case was discovered, what should be done with it? He confessed that this was a big problem confronting them. One must use a great deal of judgment and tact in making an explanation of the condition to these patients. He did not believe they should call a person tuberculous who had no symptoms of the disease. The tuberculin test was often a delusive aid, but it often helped, especially in children. With regard to artificial pneumothorax, from his point of view it was very important, especially in the treatment of the advanced cases of tuberculosis.

---

SECTION ON SURGERY.

*Wednesday, April 30.*

This was a joint session of the Section on Surgery with the Section on Medicine. The topic under discussion was duodenal ulcer.

**Etiology and Morbid Anatomy.**—Dr. Marshall Clinton, of Buffalo, read this paper. He said duodenal and gastic ulcer were so closely allied anatomically and etiologically that in a discussion of the etiology of duodenal ulcer they should take some notice of the factors that produced gastric ulcer. A great amount of experimental work in the production of ulcer had been carried out by different workers. Ulcers produced by direct trauma of the stomach wall, by feeding filth to animals, by using stomach scrapings injected into other animals to produce a cytolysis of the mucous membrane, had been followed by acute ulcer. All this experimental work had failed to this extent: chronic ulcer of the stomach or duodenum had not been produced. Acute ulcers had been formed as a result of these various experiments, but they came under the head of acute ulcers, while by custom now, when they spoke of duodenal ulcer they meant a chronic indurated ulcer. Chronic ulcer was generally rounded or oval with the long axis of the ulcer at right angles to the axis of the stomach or duodenum. The gastric juice played an undoubted rôle, for it was the usual clinical observation to find ulcer associated with an excessive quantity and a greater degree of acidity than normal. As to the pathological anatomy of ulcer, the ulcer has a typical punched out appearance. Sections of the ulcer did not seem to bear out the old idea that thrombosis played a part in its production. They believed that ulcer of the mucous membrane and deeper structures to be the result of mechanical trauma, plus a chemical action of the gastric juice. To become chronic, this trauma must be frequently repeated. The disturbance of the action of the pylorus by reflex impulses from other structures or the increase in quantity and acidity were the essential causes of chronic duodenal ulcer.

**Complications of Duodenal Ulcer.**—Dr. John B. Harvie, of Troy, said that the complications of duodenal ulcer were cancer, hemorrhage, and perforation, which would call for the most vigorous and energetic treatment. Obstruction due to contraction would permit of greater deliberation. Unfortunately, malignant disease had usually passed beyond all likelihood of successful surgical intervention when the diagnosis was made. He had met with a number of cases of inoperable carcinoma occurring in the pylorus and upper part of the duodenum, starting at the base of an old ulcer, and while careful analysis of the symptom-complex might have led to an earlier diagnosis, he had not been fortunate enough to have these cases in time to be of material benefit to the patients. If there was one department of medicine in which diagnosis was called for more promptly than others, it was the right time to interpret the significance of serious abdominal lesions. The differential diagnosis between perforation of duodenal ulcer and perforation of any other hollow viscus would present difficulties, and interpretation of the site of the lesion when general peritonitis was established, and the abdomen distended with contents, made any attempt at localization largely speculative. Males suffered more frequently than females from duodenal ulcer.

**Non-Surgical Treatment of Duodenal Ulcer.**—Dr. Charles G. Stockton, of Buffalo, said that treatment was not directed toward curing the ulcer, but in controlling the patient and in managing the digestive tract that the ulcer might heal spontaneously. The indications for treatment were (a) to require that the patient be kept in bed continously for several weeks, for it was known by assuming the upright position, bending the trunk or making movements which involved the action of the abdominal muscles, the relations of the duodenum to other parts were changed, and undue tension might thereby strain the walls of the ulcer; (b) to manage the patient so that involuntary motion of the pylorus and duodenum might be minimized, that the elements of overtonicity and spasticity of the parts might be avoided; (c) to lessen the amount of gastric secretion, with decreased acid and enzyme activity of the gastric juice before it passed the pylorus. Adrenalin in

gastric and pyloric spasm in four out of six cases was given with favorable results. In the use of adrenalin they had a fresh means of relieving a proportion of cases of gastric and pyloric spasm. Another method which acted in overcoming pyloric spasm was duodenal alimentation as advocated by Einhorn. They had in this method a new and improved means for the treatment of gastric and duodenal ulcer. He believed the time was near when this plan of treatment would supersede operative interference in a number of cases where the need of operation was now felt.

**Surgical Treatment of Duodenal Ulcer.**—Dr. JOHN B. MURPHY, of Chicago, said that the acute cases yielded very well to medical treatment. The best results were obtained by physiological and physical rest. Both medical and surgical rest was obtained in a large number of cases after the plan outlined by Dr. Stockton, if it was followed. His personal observation of twenty-one years in work of this kind had shown that they got better results in the chronic cases from surgical treatment, and that they had greater freedom from recurrences of attacks. Surgical treatment was usually instituted at a time when it was not easy to save life; but they were making great strides. When one compared the mortality of duodenal perforation of fifty years ago with the mortality of today, it was very much to the credit of the medical and surgical branches of the profession. Ninety-three per cent. of all lesions of the duodenum or duodenal ulcers occurred on the anterior surface and in the first portion. When perforation occurs, stop the leak always. Do it quickly. It was unnecessary to do gastroenterostomy at that time. Relieve the tension of the products of infection and of the material that had escaped into the free peritoneal cavity, using the Fowler position and lower abdominal drainage. Restore the patient's arterial tension immediately on the table, and while they were closing the abdomen have your assistant give intravenous transfusion if the patient was below par. On this plan a great reduction in mortality had been made. The best results at the present time were obtained by following simple means, namely, infolding of the ulcer area after the plan of Mitchell, who reported nineteen cases, with eighteen recoveries.

**The Diagnosis and Prognosis of Duodenal Ulcer.**—Dr. JAMES TAFT PILCHER, of Brooklyn, presented this paper in analysing the histories obtained from some two hundred cases of duodenal ulcer personally observed recognized in the great majority of them four pre-eminent factors. First, the *chronicity* of the complaint; second, the *periodicity* of the exacerbations of epigastric distress; third, the occurrence of *pain* of a peculiar character with precise time of onset; and, fourth, the *control* of this discomfort by the ingestion of food or alkalies, remarking that in the cases observed lately the marked period of chronicity had been reduced owing, probably, to the growing familiarity with the condition. Regarding the usual anamnesis obtained, he typified it as being found in a male who usually remarked that in the beginning of his trouble he noticed the onset of pain or burning in the pit of the stomach accompanied by sour eructations, belching and possibly regurgitation at time of small quantities of acrid material, which condition lasted from a few days to several weeks, when it suddenly ceased and was followed by a varying interval of complete health, when the same syndrome was repeated. In many cases the interval of relief was not so complete and the patient merely had his good and bad days with exacerbations at varying intervals of time. Dr. Pilcher considered the most corroborative subjective symptom possibly to be the peculiar effect that the ingestion of food had upon the epigastric distress, which act he had observed almost without exception was to be found to give immediate relief, at least in the earlier stages of the condition before complications had arisen. This phenomenon he had shown experimentally to be effected through the mechanical stimulus thus given to the stomach which excited the reflex flow of the alkaline duodenal secretion which thus neutralizes the hydrochloric acid present in the duodenum. The pain complained of was, usually, characterized as a burning or gnawing, frequently as an intense hunger amounting to an actual ache. It was also described as an "all gone" sensation. The most noteworthy fact relative to it was the remarkable precision and exactitude with which it occurred after eating, usually averaging from between two and a half to four hours, and, while differing in different patients, practically never changed in an individual case until other processes were engrafted on the original lesion. The nearer the pylorus the ulceration was the earlier seemed to be the onset of this distress. Attention was called also to the fact that in the duodenum two distinct pathologic processes were found, in that the ulcers on the anterior superior surface differed very markedly in character from those on the posterior wall. The former, as a rule, showed a very slight defect in the mucous membrane in no way corresponding to the area of infiltration felt from the outside, the orifice seldom exceeding the size of a B.B. shot, frequently being recognized as a mere slit; while those on the posterior wall approached in character the typical punched out round gastric ulcer. The latter seemed to perforate rapidly through the several coats of the intestine and were usually found to have their base formed by the pancreas which was frequently deeply invaded by them. The variation in the symptomatology evidenced by these two types of duodenal ulceration offered further data for differential diagnosis, since it was noted in the cases considered that the callous round posterior ulcers gave a much longer history, were not so acute in the differentiation in the cardinal diagnostic factors, did not suffer so much acute distress, but complained of a more continued discomfort which in turn was not affected so definitely by the intake of food and usually caused the maximum of duodenal deformity and consequently the greater degrees of stenosis. Further, they were much more easily demonstrable in the radiograph, while the anterior small ulcerations evidenced the more typical syndrome, seldom caused much deformity or stenosis, usually bled more easily and continuously and were not so easily diagnosed by *x*-ray. Regarding the accessory aids to the diagnosis of duodenal ulcer, he considered the *x*-ray as the most important, but cautioned against making too positive a diagnosis owing to the many artefacts obtainable in this region. Gastric analysis showing a marked hyperacidity was considered merely as suggestive and probably the greatest importance which might be ascribed to test meal findings was to be obtained by the analysis during one of the intervals free from distress at which time it had been noted that the acidity was usually normal or even subnormal. Blood in the stools was too variable a factor to give a position of any real diagnostic importance. Dr. Pilcher considered that one of the most essential elements to be recognized in cases of duodenal ulceration was to ascertain the etiologic factor of the process, and suggested that in referring to the condition it might be advantageous as well as instructive, whether the case be treated medically or surgically, to prefix a surname indicative of the underlying cause suggesting the terminology as jejunal, ileocecal, appendical, colonic, membranous pericolitic, static, ptotic. The prognosis was regarded as a relative question. That of anterior ulceration owing to the fact that these were the ones that perforated most frequently and also as they were the most frequent in occurrence, led one to make a rather unfavorable prognosis, if such ulcers be allowed to continue their course. Those situated posteriorly, on the other hand, although seldom perforating into the abdominal cavity were prone to inaugurate complications such as pancreatitis, common duct obstruction and duodenal stenosis, which might eventually prove quite as dangerous as the acute perforation. The engraftment of carcinoma was so rare that it might be disregarded. In many instances the prognosis was determined by that of the etiologic factor, several cases being quoted in which death occurred due to a ruptured appendix in whom duodenal ulcer was found at post mortem. While many cases entered into a state of chronic invalidism, others which must represent a large class, suffered but slight discomfort, or none at all, the speaker concluding that in cases properly chosen for medical or surgical treatment the prognosis in the very great majority was good.

Dr. ALLEN A. JONES, of Buffalo, said that hunger pain was an important symptom in the diagnosis of duodenal ulcer. Most of the cases of duodenal ulcer that came to them had this hunger pain very marked. It was not a symptom, however, on which they should diagnose positively duodenal ulcer. *X*-ray examinations were important in the chronic cases in which adhesions had formed, or in which there was partial stenosis of the pylorus and duodenum just beyond. Hematemesis was as common with duodenal as with gastric ulcer. They should advise against surgery in all cases where there was a profuse hemorrhage. Acute abdominal pain, at all times, with other symptoms was of extreme importance.

Dr. MAX EINHORN, of New York, said he had had several cases of ulcer of the stomach which had come to operation later that presented the characteristic symptoms mentioned by Dr. Pilcher of duodenal ulcer. That duodenal ulcer was no more frequent than gastric ulcer could be proven by experience. Hemorrhage was not an indication for operation. He thought ninety-nine per cent. of the cases of duodenal ulcer got well under careful, judicious medical treatment.

Dr. Robert T. Morris, of New York, said in regard to acute duodenal ulcer calling for immediate treatment that he had but one new point to offer, namely, their whole tendency was to conserve the strength of the individual in such a way that he might produce his own leucocytes, his own phagocytes, and carry on the processes of elimination himself.

Dr. Charles L. Gibson, of New York, said that one pitfall in the diagnosis was the question of free air in the peritoneal cavity masking or obliterating liver dullness. He was sorry this sign was invented, because it was one of the greatest pitfalls they had. Practitioners had refused to make a diagnosis because this sign was absent. Another pitfall was to lay undue stress on blood examinations in duodenal ulcer. One sign that occurred as a transitory one came within the first half hour, namely, pain, quite marked, in the supraclavicular fossa, right or left, more often the left in his experience. The indications for gastroenterostomy in these cases were extremely restricted.

Dr. Anthony Bassler, of New York, said the cases of duodenal ulcer with perforation were surgical; cases in which there was recurrent hemorrhage were surgical, even if the hemorrhage was moderate in amount.

**Radium in Surgery.**—Dr. Howard A. Kelly of Baltimore presented this paper. He said that radium was destined to make a change in their surgical and medical work not less and perhaps even more decided than that which followed the introduction of the *x*-ray. Radium in surgery would definitely cure many forms of cancer, especially in the early stages; it would cure ninety-six per cent. of skin cancer; it would wipe out many recurrent uterine cancers, and, if taken early, some cases of rectal cancer; it acted most favorably on parotid growths; it would cure some cancers of the lip, tongue and breast and acted positively also upon sarcomata. It also cured various other fibrous and epithelial growths, especially on the surface of the body. One of its happiest effects was in curing angiomata, even the large vascular growths which could not be treated at all surgically. In gynecology radium acted happily, aside from its value in cancer, in checking the growth of fibroid tumors of medium size, in stopping uterine hemorrhages, and in relieving some forms of pelvic inflammatory trouble. One of the happiest uses was in the cure of obstinate pruritus of the vulva and anus. In exopthalmic goitre there was a good promise of a definite field of utility resulting from Dr. Robert Abbé's work. Its use in general surgery, in dermatology and in medicine bids fair to bring about either a realignment or at least a readjustment of the work in these branches. His first experience was with a woman upon whom he had operated six years previously for carcinoma of the uterus. She had hemorrhages and he found a sinus in the right vaginal vault leading back into the posterior pelvis over the uterosacral ligament, undoubtedly a cancerous recurrence absolutely beyond operative relief. He applied radium for twenty-four hours on three successive occasions at an interval of a week. The patient recovered promptly and had remained well and free from recurrence since. Another instance was that of a patient upon whom he operated for a cervical carcinoma in a distant city. Some months later, she was sent to me by her physician with a cancerous efflorescence at the vaginal vault. Without preliminary curettage or treatment, and solely with repeated applications of radium, the disease disappeared and the patient had remained free from recurrence a year and a half. This patient received in all 4,000 millegram hour treatments. In another instance, a doctor brought his wife to him who had an extensive carcinoma infiltrating both broad ligaments. Realizing the utter impossibility of extirpating the disease, he literally carved the uterus out from the infiltrated broad ligaments and left open both the abdominal and vaginal routes in order to have free access to the diseased area. The result was a remarkable modification of the disease, the tissues becoming brawny and leathery. The excessive hemorrhagic discharges never recurred and pain was relieved, though she died subsequently from the continuance of the disease; the use of the radium was palliative in an extraordinary way. Radium was also of the utmost value in certain classes of fibroid tumors, in checking hemorrhage and stopping growth. It would check hemorrhages from hemorrhagic uteri and thus save extirpation. It was also of great value in curing certain forms of pruritus about the genitalia and anus. The outlook for radium in gynecology was therefore a hopeful one.

**Possible Errors in the Diagnosis of Abdominal Cancer—A Plea for Exploratory Laparotomy: Illustrative Cases.**—Dr. William Seaman Bainbridge of New York discussed the importance of early exploratory laparotomy in obscure abdominal conditions in which, despite the application of all modern external diagnostic measures, the true state of affairs could not be ascertained. The purpose of the paper was to emphasize the importance of exploratory laparotomy, not by statistics, but by illustrative cases, not as a last resort, but as an early means of making an absolutely correct diagnosis as to the presence, extent, and site of abdominal cancer. The most telling arguments in favor of opening the abdomen and of seeing and feeling conditions as they existed were cases in which patients had been allowed to go untreated, or to be incorrectly treated, until it was too late for curative surgical intervention, and cases in which, through inexperience, perhaps, the surgeon was unable to make the correct diagnosis even when the abdomen was opened. More frequent resort to exploratory laparotomy, and the development of skill in differential diagnosis when this was done, would be the means of saving many lives, and of prolonging the span of very many more. Dr. Bainbridge illustrated his contentions with cases falling under six categories, as follows: (1) Cases diagnosed as cancer, with no cancer present. (2) Cases of cancer, not recognized as such, but diagnosed and treated as something else. (3) Cases of small cancer, diagnosed as cancer, but having far more of something else present, the latter condition or conditions being mistaken for malignancy, or being considered too serious, in conjunction with the cancer, to warrant operative interference. (4) Cases of advanced cancer, diagnosed as such, but made seemingly hopeless by an added condition which, in itself, was not of serious moment so far as prognosis was concerned. (5) Cases in which the error in diagnosis concerned the stage or extent of the cancer. (6) Cases of cancer in which the error in diagnosis concerned the type of malignant growth. In conclusion, however, he said he would not advocate exploratory laparotomy indiscriminately.

# State Medical Licensing Boards.

## STATE BOARD EXAMINATION QUESTIONS.

### Medical Examiners of New Jersey.

*October, 1912.*

(*Continued from page 782.*)

#### PATHOLOGY.

1. Describe contractures, give causes, and varieties.
2. Give causes and symptoms of increased cerebral pressure.
3. Describe leucocytosis.

#### BACTERIOLOGY.

1. Give technique and meaning of Widal reaction.
2. Define antibodies, and state how produced.
3. What do you mean by agglutination?
4. What are Koch's postulates?

#### PRACTICE OF MEDICINE

1. Differentiate pallor, anemia, and chlorosis.
2. Differentiate vesicular and bronchial breathing.
3. Differentiate hepatic, renal, and intestinal colic.
4. Give four physical signs present in consolidation of lung tissue.
5. Describe (1) dry, and (2) moist râles, and give significance of each.
6. Describe the artificial feeding of an infant, month by month, during the first year.
7. Describe the eruption of (1) measles, (2) scarlatina, (3) varicella, and (4) variola.
8. Describe the *x*-ray. What are its uses, its dangers, and how can the latter be avoided?
9. Where and what is the cause of a systolic murmur heard at the ensiform cartilage?
10. Describe the various steps in making a complete uranalysis, giving your reasons and what you expect to find in each.

#### OBSTETRICS.

1. Define the three stages of labor, and give management of third stage.
2. Give symptoms of different degrees of mastitis, and treatment of each.
3. Give indications for the use of forceps, and describe in detail the application of median forceps.
4. Give indications for podalic version, and describe in detail how it is performed.
5. What is placenta prævia? Give symptoms and treatment.

## ANSWERS.

### PATHOLOGY.

1. *Contractures* are "states of the body in which the mobility of the limbs is lessened, and the position assumed by a limb is gradually fixed, so that it cannot be moved from that position. This occurs in two ways—a limb, for example, may be flexed by the activity of flexor muscles which are continually in a state of spasm, or by the action of normal flexors, *unopposed* by extensors, because the latter are paralyzed, while the former still receive the normal tonic impulses. This latter form of contracture is termed passive." (Adami and Macrae's *Pathology.*)

3. *Leucocytosis* is an increase in the number of leucocytes normally present in the blood. It may be *physiological* and *temporary,* as during digestion, in pregnancy, in the newborn; or *pathological,* as the result of fevers, infections, leukemia, and other diseases.

### BACTERIOLOGY.

1. *Widal's reaction* "depends upon the fact that serum from the blood of one ill with typhoid fever, mixed with a recent culture, will cause the typhoid bacilli to lose their motility and gather in groups, the whole called 'clumping.' Three drops of the blood are taken from the well washed aseptic finger tip or lobe of the ear, and each lies by itself on a sterile slide, passed through a flame and cooled just before use; this slide may be wrapped in cotton and transported for examination at the laboratory. Here one drop is mixed with a large drop of sterile water, to redissolve it. A drop from the summit of this is then mixed with six drops of fresh broth culture of the bacillus (not over twenty-four hours old) on a sterile slide. From this a small drop of mingled culture and blood is placed in the middle of a sterile cover glass, and this is inverted over a sterile hollowground slide and examined. A positive reaction is obtained when, all the bacilli present gather in one or two masses or clumps, and cease their rapid movement inside of twenty minutes." (From Thayer's *Pathology.*)

2. *Antibodies* are substances in the blood serum or other body fluids which antagonize or restrain the destructive action of bacteria. The antibodies now recognized are the antitoxins, bacteriolysins, opsonins, agglutinins and precipitins.

"Anti-substances may be arranged, as has been done by Ehrlich, into three main groups. In the first group, the anti-substance simply combines with the antigen, without, so far as we know, producing any change in it. The antitoxins are examples of this variety. In the second group, the anti-substance, in addition to combining with the antigen, produces some recognizable physical change in it; the precipitins and agglutinins may be mentioned as examples. In the third group, the anti-substance, after it has combined with the antigen, leads to the union of a third body called complement, alexine, or cytase, which is present in normal serum. As a result of the union of the three substances, a dissolving or digestive action is often to be observed. This is the mode of action of the anti-substances in the case of a hemolytic or bacteriolytic serum. So far as bacterial immunity is concerned the antiserum exerts its action either on the toxin or on the bacterium itself; that is, its action is either antitoxic or antibacterial." (*Encyclopædia Britannica.*)

3. *Agglutination* is the property possessed by the blood or blood serum of animals (and men) whereby, after an attack of an infective disease, the blood causes "clumping" of the infective agent in liquid cultures to which the serum is added. It is particularly noticeable in the case of typhoid fever.

4. To *prove that bacteria cause disease* it is essential: (1) That the microorganism be found in the tissues, blood, or secretions of a person or animal sick or dead of the disease; (2) the microorganism must be isolated and cultivated from these same sources; it must also be grown for several generations in artificial culture media; (3) the pure cultures, when thus obtained, must, on inoculation into a healthy and susceptible animal, produce the diseases in question, and (4) the same microorganisms must again be found in the tissues, blood, or secretions of the inoculated animal. These are called the rules or postulates of Koch.

### PRACTICE OF MEDICINE.

1. *Pallor* is a mere symptom, consisting of a whitish or ashen appearance. *Anemia* is a disease characterized by a diminution in the number of red corpuscles. *Chlorosis* is a disease characterized by a diminution in the quantity of hemoglobin.

2. *Vesicular breathing* is the breathing heard over the lungs in a state of health. *Bronchial breathing* is the breathing heard over the trachea and in the region of the seventh cervical spine in a state of health; and over areas of consolidation, in disease.

3.

| INTESTINAL COLIC. | BILIARY COLIC. | RENAL COLIC. |
|---|---|---|
| 1. History of having eaten improper food. | 1. History of colic, vomiting, followed by icterus. | 1. History of previous attacks and passage of calculi. |
| 2. Pain chiefly in region of umbilicus. | 2. Pain in region of liver, radiating toward umbilicus and right scapula. | 2. Pain in region of affected kidney, radiating down thigh, often accompanied by retraction of testicle. |
| 3. Absence of rigor. | 3. Sweats and chills frequent. | 3. Rigors pronounced. |

(*Pocket Cyclopedia.*)

4. *In consolidation of lung tissue,* there will be: (1) Dullness on percussion; (2) increased vocal fremitus; (3) bronchophony, and (4) bronchial or harsh respiration.

5. "*Dry râles,* for the most part, are produced by the vibration of thick fluids which the air cannot break up and which therefore temporarily lessen the caliber of the bronchial tubes. When the narrowing exists in the smaller bronchial tubes the resulting sound is high-pitched or the râle is said to be sibilant or whistling; when the narrowing exists in the larger bronchial tubes the râle is low-pitched, more musical in character, or sonorous. Dry râles are particularly prone to be dislodged by coughing, and when they are uninfluenced by the acts of breathing and coughing they do not depend upon the presence of secretions but upon the narrowing of the air-tubes from the pressure of a spasmodic contraction of the air tubes."

"*Moist râles* are those produced by the air passing through thin fluids, such as mucus, blood, serum, or pus, during the respiratory movements. When the fluid exists in the smaller bronchial tubes the râles are termed small bubbling, mucous, or subcrepitant. When the fluid is in large bronchial tubes the râles are said to be large bubbling or mucous. Moist râles are not persistent but vary in intensity, and shift their position as the air drives the liquid which occasions them before it during violent attacks of coughing or after copious expectoration." (Hughes' *Practice of Medicine.*)

6. The following formulæ, by Winters, are from Edgar's *Obstetrics:*

For the second week. *Upper 2½ ounces from a quart of milk 16 hours after milking.* Cream, 2¾ ounces; milk-sugar, 1 ounce; lime-water, 2 ounces; filtered water, 10 ounces; quantity at each feeding, 1½ ounces. Ten feedings in 24 hours.

For the fourth to eighth week. *Upper 9 ounces from a quart of milk 16 hours after milking.* Milk-sugar, 2 ounces; lime-water, 4 ounces; filtered water, enough to make 1 quart; quantity at each feeding, 2½ ounces. Ten feeding in 24 hours.

For the ninth to twelfth week. *Upper 11 ounces from a quart of milk 16 hours after milking.* Milk-sugar, 1.9 ounces; lime-water, 4 ounces; filtered water, enough to make 1 quart; quantity at each feeding, 3 ounces. Eight feedings in 24 hours.

For the fourth month. *Upper 13 ounces from a quart of milk 16 hours after milking.* Milk-sugar, 1.8 ounces; lime-water, 4 ounces; filtered water, enough to make 1 quart; quantity at each feeding, 3 to 4 ounces. Seven feedings in 24 hours.

For the fifth and sixth months. *Upper 15 ounces from a quart of milk 16 hours after milking.* Milk-sugar, 1.7 ounces; lime-water, 4 ounces; filtered water, enough to make 1 quart; quantity at each feeding, 5 to 6 ounces. Six feedings in 24 hours.

For the seventh, eighth, and ninth months. *Upper 17 ounces from a quart of milk 16 hours after milking.* Milk-sugar, 1.4 ounces; lime-water, 4 ounces; filtered water, enough to make 1 quart.

For the tenth and eleventh months. *Upper 21 ounces from a quart of milk 16 hours after milking.* Milk-sugar, 1.1 ounces; lime-water, 4 ounces; filtered water, enough to make 1 quart.

7. *Variola:* The eruption usually appears first on the forehead and wrists, and on the third or fourth day; it is first macular, then papular, then vesicular, and finally pustular; it does not appear in successive crops; the spots are multilocular, and do not collapse on being punctured; the papule is hard and shotty, and does not disappear on stretching the skin. *Varicella:* The eruption usually ap-

pears first on the trunk, is evident on the first day, comes in successive crops, is not shotty, and disappears on stretching the skin; the spots are unilocular, and collapse on being punctured. *Scarlet fever:* Period of incubation, from a few hours to seven days. Stage of invasion, twenty-four hours. Character of eruption, a scarlet punctate rash, beginning on neck and chest, then covering face and body; desquamation is scaly or in flakes. The eruption is brighter, is on a red background, punctiform, and is more uniform; the temperature is higher, the pulse quicker; the tongue is of the "strawberry" type, the lymphatics in the neck may be swollen, and there is sore throat; Konlik's spots are absent. *Measles:* Period of incubation, ten to twelve days. Stage of invasion, four days. Character of eruption, small, dark red papules with crescentic borders, beginning on face and rapidly spreading over the entire body; desquamation is branny. The eruption is darker, less uniform, more shotty; the temperature is lower, pulse slower, the tongue is not of the "strawberry" type; coryza, coughing, and sneezing may be present; Koplik's spots are present.

8. *X-rays* are "the ethereal waves or pulsations emitted from a Crookes' tube, excited by the bombardment of the anode target with the cathode rays; they are believed to be a series of short pulsations following each other at irregular intervals." (Stedman.) They are used to aid in the diagnosis of fractures, calculi, presence of foreign bodies, arthritis, aneurysms, consolidations; also as a therapeutic agent. The *dangers* are burns, dermatitis, and sterility. The rays should be used by experts only, the utmost care should be exercised, and all protection (such as lead masks, etc.) utilized.

9. A systolic murmur heard at the ensiform cartilage may denote tricuspid regurgitation.

10. *An analysis of urine* includes: Estimation of total quantity passed in twenty-four hours, color, odor, reaction, specific gravity, total solids (by aid of Haeser's coefficient). Then examine for albumin by Heller's test, or by heat and nitric acid; then for glucose, by Moore's test, with potassium hydroxide, or with Fehling's solution, which contains copper sulphate, sodium hydroxide, and Rochelle salt; then for blood with potassium hydroxide solution; then for bile pigments by Gmelin's test; then for indican, using lead acetate, hydrochloric acid, ferric chloride, and chloroform. Then quanitatively for urea, using solution of sodium hypobromite; for chlorides, with silver nitrate solution; for sulphates, with barium chloride solution. Microscopical examination should then be made for casts, cylindroids, crystals, and tubercle bacilli.

OBSTETRICS.

1. Labor is divided into three stages: The *first stage* begins with the commencement of labor, and ends with the complete dilatation of the os uteri. The *second stage* begins with the complete dilatation of the os uteri, and ends with the birth of the child. The *third stage* immediately follows the second, and ends with the expulsion of the placenta and the beginning contraction of the uterus.

"*During the third stage.* 5i of fluidextract of ergot is administered and irritation of the uterus by friction through the abdominal wall is practised for 10 or 15 minutes. If the placenta is not expelled by this time the uterus is firmly grasped between the thumb and 4 fingers and compressed. Firm pressure is then made from above downward and backward in the direction of the pelvic canal. This usually causes delivery of the placenta. A vulvar pad of salicylated cotton and carbolized gauze and an abdominal pad and binder are then applied." (*Pocket Cyclopedia.*)

2. ACUTE MASTITIS. "*Symptoms:* The breast is swollen, painful, and tender, and, owing to the soreness of the nipple, the breast is not relieved of its secretion, so that it is distended. If suppuration follows, redness, edema, and fluctuation occur over the site of the abscess. The abscess may be—(1) supramammary, the pus lying between the skin and breast; (2) intramammary, or the common form, in which the pus is in the substance of the breast; (3) submammary, which is beneath the breast, and may spread from the deep lobules, but more frequently is due to disease of the underlying ribs. *Treatment,* before suppuration occurs, consists in supporting the breast with a bandage, emptying the gland regularly with a breast-pump, and applying a belladonna plaster over the gland to stop the secretion and allay the pain. When pus is present an incision should be made at once, or the abscess may burrow extensively and riddle the breast. The incision should be made in a line radiating from the nipple, so as not to cut the ducts; it should be free, and all pockets opened up with the finger. Then a large drainage-tube is inserted and shortened daily, as the wound heals by gravitation. If necessary, several incisions are made."

CHRONIC MASTITIS. "*Symptoms:* There may or may not be pain in the breast, but a number of small scattered lumps are usually found. Both breasts are usually affected. The skin is seldom attached over the lumps, but the lymphatic glands may be slightly enlarged. Distinct cysts may be felt in some cases. The disease slowly progresses, and ends in atrophy of the breast or general cystic formation. It is said that cancer is likely to follow interstitial mastitis. *Treatment* consists in supporting the breast and applying a belladonna plaster. Single cysts should be removed, but if the whole gland is cystic complete removal is better." (*Aids to Surgery.*)

3. *Indications for the use of forceps* are: "1. *Forces at fault:* Inertia uteri in the presence of conditions likely to jeopardize the interests of mother or child. (*a*) Impending exhaustion; (*b*) arrest of head, from feeble pains. 2. *Passages at fault:* Moderate narrowing, 3¼ to 3¾ inches, true conjugate; moderate obstruction in the soft parts. 3. *Passengers at fault:* A.—Dystocia due to (*a*) occipito-posterior, (*b*) mento-anterior face, (*c*) breech arrested in cavity. B.—Evidence of fetal exhaustion (pulse above 160 or below 100 per minute). 4. *Accidental complications:* Hemorrhage; prolapsus funis; eclampsia. All acute or chronic diseases or complications in which immediate delivery is required in the interest of mother or child, or both." (From Jewett's *Practice of Obstetrics.*)

Forceps should not be used when the os is undilated, when the head is not engaged, except in placenta prævia, when the membranes are unruptured, when the disproportion between the child's head and the parturient canal is too great, or in impossible positions and presentations. Before applying the instruments they should be sterilized, preferably by boiling; and the patient anesthetized and placed in the lithotomy position. Two fingers of the right hand are introduced into the vagina; the left blade of the forceps is then held almost perpendicularly by the left hand, with the tip of the blade opposite the vulva; the tip is introduced into the vagina, passed along the floor toward the sacrum. The blade is rotated outward in its long axis in order to escape the promontory of the sacrum. The right blade is introduced in a similar manner. To facilitate locking, one of the blades must be rotated forward. If the head occupies the right oblique diameter, as in L. O. A and R. O. P. positions, the right blade must be rotated; if it occupies the left oblique diameter, the left blade must be rotated. Traction is made in the direction of the pelvic axis until the perineum is well distended. The perineum is then protected by one hand, while the face is swept over it by an upward movement of the forceps. In posterior positions it is necessary to remove the instruments after the head is drawn down to the pelvic floor; after anterior rotation is secured they may be reapplied. If the occiput rotates into the hollow of the sacrum the hands should be depressed as the face is swept out under the symphysis pubis. (*Pocket Cyclopedia.*)

4. The *indications for podalic version* are: (1) Transverse presentations; (2) placenta prævia; (3) malpresentation of the head; (4) simple flattened pelvis, and in minor degrees of pelvic contraction; (5) prolapsed funis; (6) sudden death of the mother; and (7) any case where speedy delivery is imperative.

*Braxton Hicks' method of bipolar (podalic) version:* "The patient should be placed in the lithotomy position and be deeply anesthetized, to relax the parts and allow the whole hand to be pushed into the vagina. The external hand is placed over the breech, so as to depress it; while the presenting part is tilted away from the brim by the fingers inserted through the os. The fingers press against the front of the child and flexion is lessened. When the head is out of the brim the external hand can be used to elevate it towards the fundus. As soon as a knee or foot comes within reach of the internal fingers, it should be caught and brought into the brim, the membrane being ruptured at the same time. If the os is fully dilated, delivery may be finished at once, as in an ordinary breech case; but if the os is only partially dilated, it must be left to nature, to allow of dilatation." (Jardine's *Delayed and Complicated Labor.*)

5. *Placenta prævia* is the condition in which the placenta is attached in the lower uterine segment, and may be near or over (partially or completely) the internal os. *Symptoms:* Sudden hemorrhage, accompanied by syncope, vertigo, restlessness, and feeble pulse. *Treatment:* Stop the hemorrhage by a vaginal tampon; this must be tight and thorough. *Accouchement forcé* is indicated; this consists of dilatation of cervix, version, and immediate extraction of the child.

### CERTAIN ELEMENTARY CONCEPTS IN EDUCATION APPLIED TO MEDICINE.*

BY J. GEORGE ADAMI, M.D., SCD., LL.D., F.R.S.,

MONTREAL.

WHEN your president honored me with an invitation to deliver the annual oration before your Society, and expressed the wish that I should take up an educational topic, I found on looking back that I had given expression to opinions upon divers aspects of general and medical education before various bodies—medical students, graduating nurses, educational experts, and even that distinctively Canadian institution, a "Canadian Club," but never before a general assembly of members of our profession such as this, never before the body which beyond all others is most vitally interested in the subject. I have arrived at very definite, not to say unorthodox conclusions, and now at the risk that some here present may have happened upon reports of those previous addresses—though I do not think that the chance is other than remote—and may recognize in what I say to-day very audible echoes of these previous pronouncements, it has struck me that it would be serviceable to put before you the opinions of an outsider upon modern educational methods, in vogue in this country, and more particularly in this State. It may be that as an outsider, of necessity not so intimately informed as are the inhabitants of the State, my impressions in regard to certain matters may be wholly wrong. I doubt, however, whether my knowledge of conditions be found very erroneous and that, because we in Canada are terrible copyists of Statesian fashions: we belong, after all, to the same race, and have before us the same difficulties. I trust, therefore, gentlemen, that you will not regard me as a Balaam and —to continue the parable—I trust that no one here present and so regarding me will turn balky. But, speaking seriously, it would pain me did anyone for a moment think that I ill repaid your hospitality by criticising educational conditions in this country. I can only say that I have been permitted to enter into the medical life of the States to such an extent that I have been made to regard myself as one of yourselves.

I want in the first place to put before you sundry basal considerations regarding education in general, to apply them to medical education, and then more particularly to the requirements of the State of New York as determined by that august body the Regents. It is because that august body lays such stress upon preliminary education and fences admission to the study of our subject with a series of such cast-iron requirements that I have to make so elementary a start. And as these requirements are based upon the primary and secondary school system of the State of New York, I have therefore the temerity to enquire into the value of that system. Wherefore, if you like so to consider it, of malice prepense, I may shock some of you. It is easy, in these days of general well-being, to hold with Candide that all's for the best in the best of all possible worlds; that the system of education which has been elaborated in this great country, the system under which most here present have been brought up, is the system best adapted to the genius of your people: that there is no nobler system than the public school system of the United States, and coming nearer home, that there is no more perfect system of preparation, education, and examination in medicine than that devised and demanded in their wisdom by those grave and reverend seniors, the Regents of this State. Permit me to give you to think.

To begin with, what is the main object of State-controlled education? Is it to ensure that every citizen is provided with a certain common or minimum stock of information upon various subjects, or is it, on the other hand, to ensure successive generations of citizens capable of serving the State? This last possibility may be a new thought to some here present, but on consideration I think you must agree with me that this, and not the benefit of the individual, is the primary object. However much it may matter to the individual to be an efficient scholar, it matters little or nothing to the State that a given proportion of its boys and girls know the Latin irregular verbs, or only so much as it affords evidence that these have gained the habit of application; it matters everything that during the labile years their characters be developed and brought out, that the State be provided with capable citizens. *Instruction,* the pumping-in process, is of use only so far as it provides a basis of data for *education,* the drawing out of what is best in the individual. And I would bring two indictments against the public school teaching of the State, and doing this I indict equally the teaching of other States, and of the Canadian provinces, including my own benighted province of Quebec, namely, that there is too much instruction, too little education, with the resultant danger of the production of a race that is thoughtless and characterless.

In the words of one who has done very much to raise the standard of medical education on this continent, who may indeed be regarded as today the leader in the movement: "Where you have a weak secondary school system, you cannot expect to improve the schools above it until you have made the secondary school all it ought to be." We university professors have presenting themselves before us what I suppose are the pick of the products of the public school system. What do we find? It is a painful admission, but the majority when they

*Read at the annual meeting of the Medical Society of the State of New York, at Rochester, April 29, 1913.

reach us are fair poll-parrots; they can pump out what has been pumped in; but it is distinctly the minority, and let me say, a small one at that, who can utilize their frontal lobes and put two and two together. Now it is right that training should begin with respect for authority, that the pupil should begin with a respect for the written word, that he should look up to his pastors and masters and accept their statements as true and sufficient. The instilling of respect for authority is the first step in education. But this does not mean that the pupil is only to memorize and not to think; that by the time he is seventeen or eighteen he is still to be fearful of testing conclusions for himself; that he is not to be drawn to use his brain and make his own conclusions. And yet I am credibly informed that so essential a part of the present system have become the methods of the University of Cairo, that these extend to certain American colleges and universities, and in them it is forbidden to put examination questions which, for a correct answer, do not immediately refer to the *ipsissima verba* of the lecture and the recommended text book, but require some correlation of the data afforded in the course, some application of thought and not merely of memory. Now for us medical men, each case, as we know, possesses factors which make it a different problem from all that have gone before; each case to be correctly diagnosed and treated requires thought. I may be wrong, but it seems to me that the youth should be trained to think before reaching the medical school. I feel this very strongly: I feel that the secondary education is seriously defective in permitting such lack of thought; that the system of examination is wrong which makes entrance to medicine depend purely upon knowledge of facts, which is based wholly upon the capacity for the recollection of unrelated statements, which does not by an essay, or still better, by an oral examination, test the intelligence as distinct from the memorizing power of the candidate. Naturally what appeals to examining boards as most appropriate is that system of examination which can be carried out most simply and most economically; and if a board, instead of employing expert and highly paid examiners, places the actual reading of examination papers in the hands of clerks who have no intimate knowledge of the subject of examination, but who automatically mark according to a schedule which is provided to them, it is evident, in the first place, that those questions only can be set which afford a stereotyped answer and call for no thoughtful weighing of *pros* and *cons*, no evidence of the power to balance evidence, and, in the second place, that a heavy penalty is by this method exacted against teachers who in their classes encourage anything beyond exact poll-parrot memorizing. If this be the case—and I sincerely hope that it is not even partially true—there is likely to be opposition to the suggestion that there be appointed examiners who are truly examiners, experts in their respective subjects, men capable of judging qualitatively as well as quantitatively.

He who studies the Public Health Law of the State of New York as it refers to medical education and the regulations for the admission to medical practice, cannot but be impressed by the rigid rules laid down in regard to preliminary training. Thus, according to Section 165, the candidate must submit evidence that prior to the beginning of his second year of medical education he has acquired that "general education required preliminary to receiving the Degree of Bachelor or Doctor of Medicine in (the) State." In other words, no university in the State can determine for itself whether a candidate is of proper standing, not for the State license, but for its own degrees in medicine. That is determined for it by the Regents, and is dependent primarily upon the nature of the education the candidate has received prior to entering the medical school. If a student has graduated in arts in another state or country, such graduation is only accepted if from a registered college, and then on the conditions that "such college course shall have included not less than the minimum college requirements prescribed by the Regents for such admission to advanced study." If he possess a diploma or license conferring full right to practise in some foreign country, that diploma or license is not sufficient, he must also submit evidence that "he is a graduate in arts of a registered college in that other country, or that he has satisfactorily completed a full course in a registered academy or high school" (registered, that is, by the Regents); "or had a preliminary education accepted by the Regents as fully equivalent." Then there are regulations providing for the conditional matriculation of a student deficient in not more than one year's academic work of 15 counts of the preliminary education requirements, provided that the deficiency is filed at the Regents' office within three months after matriculation; provided, also, that on and after January 1, 1913, such conditional matriculation shall not be permitted. At the present moment, therefore, no student can enter medicine unless his preliminary training conforms with the requirements of the Regents to the uttermost jot and tittle.

The preliminary requirement determining admission to registered medical schools is the completion of an approved four-year high school course or its equivalent. The official evidence of the fulfilment of this requirement may be secured in various ways: By certificate to this effect from an approved secondary school; by passing the Regents' examination in the schools; by presenting evidences of the successful completion of one full year's work in an approved college or university, or of work in another state or country equivalent to this four-year course in a New York secondary school; by presenting evidence from a registered school of theology, law, dentistry, pharmacy, or veterinary medicine of the completion of work equivalent to one or more year's work in an approved secondary school, together with sufficient additional credits to make the full equivalent of a four-year course in an approved high school; or if by any one of these means the candidate is unable to enter, then he must pass the Regents' examination, but doing this must gain a rating of 75 *per cent.* in each of *nine* subjects, namely, in English, algebra, plane geometry; two out of three following subjects, chemistry, physics, and biology; one second year foreign language, ancient history with civics, and two or more (15 counts) of a long series of electives—English, ancient and modern languages, advanced mathematics, history, geography, economics, bookkeeping, shorthand, drawing.

As to what constitutes an approved secondary course, the Regents are thoughtful enough to lay down a time table for each of the four years, giving the number of periods which they regard as essential in each subject, even down to manual training and vocal music. As I say, it is most thoughtful of them. For a medical school to be approved by the Regents, all matriculants must afford evi-

dence of a general preliminary education equivalent to at least a four-year high school course after eight years of preliminary education. Any medical school that matriculates a student who has not completely complied with the admission requirements must be forthwith excluded from the list of approved schools. "A medical degree from a registered institution does not meet with the educational requirements for admission to the licensing examination; evidence of preliminary education as well as evidences of required attendance at a registered medical school are essentials."

I have recited to you in detail all these bald regulations of the Regents that I may impress upon you what is evidently the main premiss of the Regents, namely, that the requisite standard of medical education can only be attained by rigidly fixing the minimum preliminary training of the student; however distinguished has been his record as a medical student, unless that preliminary standard has been attained, it is hopeless for any one to seek to practise medicine in this State, save under conditions that are tantamount to exclusion. If the matriculation examination of a university outside the State of New York does not in the opinion of the Regents exactly conform with that demanded by them, that university cannot be registered. If that university influenced by different ideas and different traditions has evolved a somewhat different matriculation standard and medical curriculum from those regarded as right and fitting by the Regents of the State of New York, either it must humbly submit to the dictates of that august body, or must incur the penalty of seeing its graduates prevented in perpetuity from practising in the State, and that however thorough their medical education, however distinguished their Alma Mater, however excellent their degree; their preliminary education requirement was not such as to satisfy the fastidious tastes of the Regents.

Surely there is "something rotten in the State of" —New York and its educational system that this should be, that the Regents must thus force all the universities of this continent to bow to the graven image which they have erected. Of course, I know the basic reason for this conduct: that the education afforded in certain medical schools in the State has, in the past, been deplorable, that these schools have to be brought into line, that in the past every illiterate Tom, Dick, and Harry could enter as a medical student; that this had to be stopped; that to prevent any backsliding on the part of these weak schools the regulations have to be of the sternest and there must not be even the appearance of making concessions to universities outside the State, however admirable the courses they provide and however great their reputation, lest, doing so, precedents and loopholes be afforded to these weaker brethren for evasion of the regulations, and opportunity for their alumni to creep or intrude or climb into the fold.

This, it will be observed, is an argument of expediency, not of right. The Regents will not pretend to say that theirs is the only correct ideal, that they do well in hampering other universities outside the state in their endeavors to evolve a sound course of medical education along lines which in important respects differ from the New York regulations, or do they? and is there a belief on this continent as indicated by their action, and to some extent, I think, by the first Carnegie report, that it is possible to plot out the whole working years of the would-be practitioner from the age of sixteen until his graduation—to construct an ideal time table, any departure from which is an intolerable step from grace. Such hidebound rules are, to say the least, unscientific and bound to fail. Education is a progressive science; while what is admirable in one community may be disastrous in another. Let me give you an example. The quality of the instruction in elementary science in the secondary schools is still a matter of debate. I think all will agree that those secondary schools can usefully afford instruction in the very elements of science, the student, for instance, should arrive at the medical college knowing of the existence of elements, and the nature of a chemical reaction. I have serious doubts whether, save in the rarest cases, the teaching of the secondary schools is according to the right ideals of education in elementary science. To quote my colleague, Dr. Ruttan, "You will never acquire a scientific training from a mere literary acquaintance with chemical facts and theories; in this way you will acquire only scientific information, an altogether different thing." Even if laboratory courses are afforded, the method of following an accredited text book has practically no educational value. What is needed is that each experiment in the laboratory is made an exercise in rigid observation, and in the solving of problems, the answer to those problems being observed and recorded by the student, and not discovered from the text book, or announced by the teacher. Obviously he will be in a better position to grasp the fundamentals of chemistry, physics, and biology in the laboratories of the medical school or university under university teachers than in the too often imperfect surroundings of the high school. In one hour under these more favorable conditions, the student should acquire more chemical and biological knowledge than in five spent in the high school. But the grave Regents, with their vertebral ankylosis, think otherwise: they demand the same number of periods wherever and whenever the instruction be gained. They penalize the medical school which seeks to afford the more thorough course.

Instinctively, when it is placed before you in all its baldness, you realize that there is something inherently defective in these regulations, and if I may place my finger upon the weak spot it is this: that the fundamental conception upon which the whole superstructure of the primary, secondary, and university training is sought to be built is false. The whole system, you will observe, is based upon "periods" and "counts," upon the *quantity* and not upon the *quality* of the teaching. The quality is of secondary importance. No matter how excellent the training to which the applicant for a license has been subjected, if he cannot afford certificates that he has undergone so many periods, so many hours of instruction, equivalent to eight years' primary schooling and four years' secondary, he cannot enter into the State of New York. The outward and visible sign of the inward and spiritual grace is not intelligence but "counts." The machine has become of higher value than its product.

Do you see what this aspect of affairs signifies, not merely for our profession, but for the upbringing of all the inhabitants of the State? And here let me again emphasize that I am using the State of New York as a text, not as the one and only malefactor. This precise laying out of every hour in every public school throughout the state means intellectual perdition. It means, if logically fol-

lowed out, that at the present hour in every secondary school throughout the State every boy and every girl who is in, say, the second class, is having identically the same facts doled out to them. It means that at the conclusion of the school course every individual has one common set of ideas. If there be individuality among the scholars, the State has done nothing to foster, but on the contrary everything to discourage it. It means that we are drifting to a Chinese civilization, with official arrest of all initiative. This may be gloriously socialistic, but does not make for the progressive development of the people. Where all the members of a community have a common dead level of training, they manifest the same character, or, more accurately become manifestly characterless.

It means that with this emphasis upon the necessity of completing so many periods in each subject, teachers and taught are alike discouraged from effort and ambition. I believe that all who have inquired into the subject will absolutely uphold me when I lay down that a reasonably intelligent youth can easily master the subjects demanded in the four years' secondary school course in three years; some tell me, in two. But no, he must not do so; he must remain so many months in this class, so many in that—that he may complete the required number of periods; he must be kept back so that he does not advance beyond the others of his year; he must acquire habits of mental sloth. And this all because of this precious belief of the powers that be in the virtues of a pernicious system. The minimum of encouragement is given to the teacher to enter into the highest joy of teaching, that namely, of stimulating and pressing forward the promising scholar.

It means, also, gentlemen, the domination of the female teacher. Such precisely devised system is exactly suited to her inherent genius, it is wholly alien to the genius of the ordinary male; I do not here refer to those who evolved it; they are extraordinary.

Do not regard me as digressing, if as a *vox clamans in deserto,* I proclaim my opinion of the female teacher as an educator of male youth. Now that I am embarked upon a criticism of secondary education it is essential that I refer to this other weakness that is overwhelming the continent. Once again we revert to the main thesis that the pedagogues who have developed and are still developing our system appear to be absolutely blind as to the all-important distinction between instruction and education. Even so distinguished and well-meaning a body as the Carnegie Foundation in that report upon medical education to which I have already referred, was tarred with the same brush. In criticising and laying down what they regarded as the elements of a good medical education, not one word was said by the authors of that report regarding anything beyond the acquirement of a knowledge of medical facts and technique. It is tacitly assumed that this is everything. And yet you, gentlemen, who are in practise know perfectly well that in life such knowledge does not count fifty per cent. It is the man within the medical shell that is all important. What J. Pierpont Morgan said but a few weeks before his death regarding business credit is equally true of professional reputation and success; it is character that counts, character that makes the man. What a man teaches is not half the game; how he teaches it counts, I would almost say, everything. Of greater value than mere facts is the attitude of the medical teacher towards life, his method of approach toward the patient, all those traits of manner, expressive of the inner being, which at the most receptive period of life appeal to the student, are imitated and become in turn a part of his being. Of prime value also is the university education outside the classroom, the laboratory, and the ward; so valuable is this that the medical school must be an integral and intimate part of a university of several faculties, in order that the student may mingle with men of other ideals, other habits of thought and modes of life. Your medical man to be of service to this kind must have an education in, and must know humanity. Unfortunately all these aspects of his training were completely ignored in that most important and otherwise most stimulating report.

But this education is the man's duty to his neighbor, this training in service to others must begin in the secondary school—aye, in the primary school. Heaven save the youth who between the years of twelve and eighteen is in the hands of women—women only—as teachers, who is devoid of practical training in manliness. It is the right and proper thing that the early teaching of the little boy should be in the hands of women; it is well that there be a gradual tansition from the mother's influence at home to the rougher world outside; but there comes the time when the boy begins to "feel his oats," when the budding youth fast becomes restive, when if the boy is to develop aright a masculine hand is needed at the reins. Of course, there are "sissies" and boys of phlegmatic temperament who remain eminently docile under feminine guidance; your boy with any vigor and initiative, the boy who is going to do something in the world, must be under a man. For otherwise he soon recognizes that he is too strong for his teacher, he sees that she is powerless to compel him, recognizes that owing to her physical weakness she has to appeal rather than to compel, that she has to gain her ends by oblique methods—by persuasion and not by command. He learns thus to get around difficulties without facing them manfully; does as he pleases heedless of others; becomes a selfish individualist. You may say that this is too strong a statement. I only know that a few months ago I was discussing this very matter with a remarkable woman, one whom I may without exaggeration describe as the foremost woman educationalist in Canada. "Yes," she said, "you are right. Only last week a bright school teacher admitted to me that the one means she had discovered whereby she could manage hulking youths was by indulging in a mild flirtation with them." The aboriginal woman's way, but, oh, God; the miserableness of it all! Is that how we want our boys brought up?

I feel in this relationship most heartily in sympathy with a colleague of mine—incidentally a Presbyterian minister—though I doubt if in that audience I would have had his noble temerity. It was a few weeks ago, at a meeting in support of our University Settlement, and my friend was called upon to address the assembly, a large one, composed almost entirely of the gentler sex, there being but three or four of us men present. "And don't get into your heads," said he, "that you are going to run this settlement, that you are going to reform these street urchins and potential hooligans by 'lev' —'Lev!' Bah! If you try that they will fool you every time. No! It must be by manly guidance and by manly methods, even including an unhesitating knockdown blow when need arises. It's the manly man they will look up to, and by whom they will

most surely be influenced. They will not 'lev' him, they will worship him. I hold it to be the supreme argument for design in this universe that the boy is so constituted that the greatest number of nerve endings of the greatest number of nerves find themselves in that portion of his anatomy where knowledge can most neatly and effectually be instilled and that with absolutely no harm to the rest of the economy."

I freely admit—we all admit—that in those qualities which are the common property of both sexes, the woman is demonstrably man's superior; but in the matter of enforcing authority on the growing youth of the male denomination she is hopelessly and helplessly behind. To the present exaltation of feminine and lowering of masculine influence in the home and in the school I would ascribe both the growing increase in juvenile crime, and the appalling increase in domestic misery in this country. Boys and girls spoiled in the training, undisciplined, not to say encouraged to carry out their own wishes, become immoral individualists, cannot bear with patience the necessary give and take of married life, and the divorce court is the result.

Once again let me repeat that education is much more than the instilling of facts into the brain. It is the whole proper development of the individual. In the playground, even more than within the school, the masculine influence is needed, that the boy be instructed to play not for himself, his own advantage, and his own glory, but before all other considerations to act as one of a team, for the good of that team and for the honor of the school. How can the female teacher participate and direct the game of football, of hockey or baseball? How can she practically instil these lessons of obedience and willing subordination of the individual for the common good which constitute the essence of all games worth the name, which constitute the essence of civic virtue and public spirit. It is not in her. Better an unlettered drill sergeant. The playground teaches civics better than any number of periods in class, and the master is needed to enthuse the right spirit. You know how things are going in this State; the situation is notorious. But it is as bad, and worse, elsewhere. Last year in the Protestant Normal School of our own Province of Quebec out of an entry of 150 prospective elementary teachers there were just three males.

But, it may be urged, what is the use of all this destructive criticism? Well, gentlemen, I freely admit that destructive criticism *per se* is worse than useless if there be nothing constructive afforded. I believe that these defects are one and all capable of a remedy. And to begin at the beginning, and take the last first, I would urge that it is in the power of the State to obtain the male teachers so absolutely essential for the training of male youth. By all means let female teachers be given a proper wage, but surely the logic of stern facts must lead us all to realize that under present conditions there is little to attract men into the public school teaching profession, and must equally convince us that for the good of our youths, men have to be attracted; nay, must convince us that, if necessary, in order to attract them, greater inducements must be afforded to them than to their sisters. That profession to-day is a blind alley. No man with any initiative, with any self-respect will undertake the automatic duties laid down by the Regents and the educational departments of the States of this Union, with every hour's work scheduled, with its precise limitations to the scope of certain text books, with its painful lack of encouragement of higher effort. The cast-iron drudgery and servitude of it all, and its highest reward the very moderate income and status of the principal of a secondary school! Make the profession not a blind alley, but an open highway! The State has appointed for the taught a graded course from the primary school through the secondary to the university. Why not also for the teacher I would suggest that, in the first place, promising youths be tempted to undertake teaching in the primary schools on the condition that two years thus spent in the service of the State shall entitle the teacher to one year's free tuition at the State university, that each subsequent year of teaching shall entitle him to a year's free university education. Nay, more, the State might well establish a residence at the State university where such State servants might board at a minimum cost. The young teacher should be free to choose his university course in such a way that he might undertake four or five years of State service as a means of putting himself through any one of the faculties and entering any one of the professions. If, on the other hand, he determined to make teaching his vocation, then after gaining his degree in arts and, earlier or coincidently, promotion from a primary to a secondary school appointment, it should be imperative that every few years, as in the army medical service, the teacher return to headquarters, in this case to the university, for advanced work along some special line, he becoming for the time being a junior member of the university staff. Every encouragement should be given to the good teacher to become an expert in some one or other department of learning, and it is but right and proper that he be given the hope and the opportunity to secure eventually a permanent university post in the subject to which he has specially devoted himself. He should be encouraged to realize that it is open to him to reach the top of the educational tree.

Next, as to the curriculum, and here my recommendations apply both to the schools and to the medical course, I would here repeat what I said two years ago at Chicago, that the finest national education known to me—no longer, alas, in existence, for the growing wave of State socialism has changed everything—was that established in Scotland by the dour but powerful reformer, John Knox. There were in it no school-marms, but every village, or more accurately every parish, had its school house and its dominie, wherever possible a university graduate, even if only a "stickit minister." There were in it no State-regulated schedules of hours, but the dominie was expected to bring all his scholars up to a sound familiarity with the "three R's" and was stimulated to advance the more promising pupils up to university standing. To matriculate it was necessary that those scholars had a wide teaching, but beyond this the dominie gained his great triumph by securing for those scholars university prizes and bursaries. If the master was a classical scholar, then the school excelled in classics, if a mathematician, in mathematics, if a Hebraist, then, even, in Hebrew. Each school, thus, was distinctive, and the result was not a tame level of commonplace knowledge, but the production of scholars of varied attainments and, what is more, of character. For its size no country in the world has during the last two centuries turned out more men of distinction in the

varied walks of life, more men of character, more leaders in the different departments of human endeavor than has Scotland, and this, I am convinced, is due to John Knox and his dominies. Demand, I would say, that every entrant to the university have a competent knowledge of a definite schedule of subjects, nay I would say, demand a higher standard than that at present in vogue, but do away with this deadening system of compulsory periods. Encourage the rapid promotion of the intelligent boy: encourage him to rise rapidly through the secondary school; give him the time to spend two years in the arts department of a university. For otherwise, if we carry out the programme as at present recommended, namely, eight years primary school, four years' secondary school, two years in arts, four years in the medical school, a year, or better, two years in hospital—the man by the time he enters practice has become so steeped in academic methods that he has lost all the elasticity of youth, is incapable of adaptation to the wear and tear of practical life; brilliant and accomplished as he may be as a student, he owes to something in himself beyond his training if he is not a failure as a general practitioner.

It is a matter well worthy of debate, whether in place of a matriculation examination on the part of the universities, there should not be a "leaving" or "Abiturient" school examination controlled by the State, an examination which youths should be invited to undertake, not when they reach a particular age, or when they have accomplished a given number of periods, but when they have gained the requisite knowledge. Such an examination would afford a standard test of the teaching afforded by the secondary schools throughout the State, a standard to which they should raise themselves, and certainly, as I have already noted, it should include some test of the candidate's intelligence as distinct from his memorizing ability. Let me sum up here as regards school and university training, that it is contrary to common sense to appraise the tree by the amount of manure with which its roots have been dressed and the number of times it has been watered: it is rather more usual as it is more sane, to estimate its value by the crop it produces. "By their fruits shall ye know them." Indeed I believe that those of you who are arboriculturists will confirm the statement that too rich a soil, too abundant manure and excessive irrigation, instead of giving a good crop, have the opposite effect. Would that the Regents of the State took this to their hearts.

And so with the test of the fitness of the university graduate to practise. It is absolutely false to imagine that by a cast-iron curriculum and a written examination, and that alone, it is possible to assure and determine the quality of a candidate. What do we see as the result of this policy? Why this, that the products of night schools and other wretched so-called institutions of learning are admitted into the profession as readily as are the alumni of the highest and best schools on this continent—men whose preliminary scientific training has been a farce, who have learned their anatomy not from dissection, but from quiz compends, who have not been within the wards of a hospital, but at the very most have seen patients from the seats of an amphitheatre, men who to save their souls could not percuss a heart or recognize normal breath sounds through a stethoscope. You know, we all know, gentlemen, that these written State examinations, with papers set and passed upon by those who are not experts, with no adequate oral and practical examinations are wholly rotten. I have used this word before, I do not hesitate to use it again. I know that the Regents are seeking to remedy this state of affairs, but they have not gone far enough. But how is this to be corrected?

I am going to make a bold recommendation, but I am convinced that the time is ripe for it. This matter of medical education is no longer a State matter only; it is one of interstate concern. If a man of this State wishes to pursue his medical studies in one of the great universities outside the State, why penalize him in order to bring the weaker schools of this State up to a higher standard? If a man from another State seeks to increase the population of this, why be so mediæval, so chauvinistic as to erect unworthy barriers against his entrance? We are apt to run down the Old Country as unprogressive, but after more than twenty years upon this continent I am slowly coming to believe that there is an extraordinary amount of hard, common sense in many of its methods. These methods may not have been arrived at by pure logic—they never have!—but by compromise. Nevertheless they fit the case. It has not attained to the one portal system: we are just about to try that in Canada as an optional method, and now that we are endeavoring to put it into execution we realize its difficulties. It is at the least an interesting experiment. But there has been established for now many years a General Medical Council for the United Kingdom. That council registers all duly qualified medical men. And here is the significant fact: that council conducts no examinations. What it does is this: from time to time it sends to the various schools a small and select committee of two or three experts, men high in our profession. That committee reports upon the quality of the instruction provided at those schools: it is present at the examinations and reports upon their scope and efficiency, and according to the report given, so does the council as a body approve of the school, in which case its diploma is accepted as qualifying for registration, or disapprove of the school, in which case specific reasons are given, and the representatives of the school are afforded the opportunity to present their side of the case. Finally if the recommendations of the committee are supported by the council as a body, either the school has to modify its procedure forthwith in agreement with those recommendations, or it has to cease to exist. Certain common regulations are laid down as to length of curriculum, essential subjects for preliminary and professional training and so on, to which all schools must subscribe, but the final approval rests not upon quantity but upon quality of the education and examination afforded.

The time, it seems to me, is ripe for a similar procedure here in the United States, for the appointment of a Federal Medical Council, subsidized by the government at Washington, and formed of representatives from all the States, a council which should appoint well-known leaders of the profession to act as committees or assessors to visit, report upon and make recommendations regarding the efficiency and deficiencies of the individual medical schools of this continent, the expenses of such inquisitions to be met by the schools visited. The Carnegie Foundation has prepared the way, but we

need now, not a private but a national institution, an institution authorized not by the profession alone, by the American Medical Association, for example, but by the nation at large, which shall act authoritatively in these matters. I would say, let each State control and direct its own educational methods. We do not want, we must fight against, any dead level of sameness in procedure and outfit. But let the Federal assessors test the results and make sure that they reach the desired standard of quality. If this be asking too much at the present moment, at least the State might take action, might appoint committees of inquisition to inquire and report upon the quality of the instruction afforded and the examinations of the schools within its boundaries, and might accept the graduates of those schools without the present farce of an examination which does not educe the capacity of the examinee.

I shall be satisfied, gentlemen, if I have impressed upon you that education is something beyond mere instruction; that we are every whit as much interested in the quality of the secondary school education as in medical education proper; that both in secondary and medical education there must be more elasticity, more freedom allowed for the individual school to control its own development; that sameness means not perfection but intellectual death. I shall be satisfied indeed if I make you think over these matters. I have said, and am content, even if after me comes the deluge.

## THE PREVENTION AND CURE OF CANCER.

A PUBLIC ADDRESS.*

By PARKER SYMS, M.D.,

NEW YORK.

By cancer is meant a tumor or new growth which is made up of epithelial cells and which is malignant in its character. By malignant we mean that it has a tendency to grow continuously until it has destroyed life; also that it has a tendency to recur or redevelop when operated upon, and also that it has a tendency to become disseminated and thus to develop in other parts of the body. There are several forms of malignant tumors. In this address I shall confine myself entirely to a consideration of cancer in its various types and shall not speak of sarcoma, of which there are several varieties.

Cancer is such a terrible enemy to mankind that it is very fitting that we should devote our energies and thoughts to it as a problem, striving in every way to lessen its ravages. It is high time that the medical profession should have an awakening. This awakening should be very wide, for it behooves us to be very wide awake. And it is high time that the public should be aroused by the spreading of as much knowledge as can be helpful and not harmful. The only way in which we can combat cancer with our present limited knowledge is by an intelligent cooperation between the patient and the doctor, between the public and the medical profession. To this end it is of equal importance that there should be a further dissemination of knowledge, not only among the lay public but also throughout the medical profession at large.

The fact that the treatment of cancer has largely resulted in failure is often spoken of as a reproach to the medical profession. This is not the thing with which we should reproach ourselves if we are doing our best. But we have not been doing our best and certainly that is a great cause for reproach.

There has been a tremendous amount of research work by certain members of the medical profession. Most elaborate investigation, both in the form of study and in the form of experimentation, has been carried on. One could hardly conceive of the vast amount of untiring work that has been done in this field. It is not with lack of such work and effort that the medical profession is to be charged. What we must remedy is a lack of standardization among themselves, a lack in the average. There has been a lack of appreciation and comprehension of facts that have been fully demonstrated. The medical profession as a whole has not been employing in the practice of medicine important facts which have been demonstrated by the science of medicine. It does not do for a few doctors to know these open secrets. They must be the common property of all the members of the medical profession, for they must be used in everyday practice, and many of them must be known to the public as well. In this way only can we improve the results in our combat with this deadly enemy cancer. It is necessary that we should use all of our knowledge all of the time. It does not do to use part of it part of the time, and that is what we have been doing in the past.

The title of this address, "The Prevention and Cure of Cancer," is certainly an ambitious one, for we cannot prevent, nor can we cure all cancer. But it is not a presumptuous title, nor a preposterous theme, for we can prevent and we can cure a great deal of cancer. And by properly applying certain facts which we have at our command we can improve our results so that those obtained at present may be looked back upon as a sad instance of shortcoming and lack of common sense.

You are all familiar with the fight which has been made against tuberculosis. To my mind the real value of the modern attack on that deadly foe dates from the time when laymen entered the field. A tremendous impetus was imparted and a tremendous amount of good resulted from a brochure written, not by a doctor but by a layman. I refer to the article entitled "Consumption: The Great White Plague," written by Mr. Eugene Wood. At the time of its publication this article was widely disseminated and created a great deal of interest not only among the laity but also among medical men, and I believe that it and similar efforts have done much to arouse the medical profession and the public to the fight which has been so nobly carried on. By such writings we were taught to set aside many of our faulty methods of approaching the subject of tuberculosis. We were taught from the standpoint of the patient. We were taught for the first time that frankness and truthfulness could be employed in dealing with these unfortunate sufferers. This truthfulness became possible and proper because we could look upon tuberculosis with hopefulness and not with despair. When you can give a man a word of hope there is no reason why you should not tell him the truth.

Among the important facts which were brought out and dwelt upon with emphasis were: (1) Tuberculosis is communicable; (2) Tuberculosis is preventable; (3) Tuberculosis is curable. By neglect of these three facts and by ignoring these three facts how impossible would be the fight against tuberculosis. Think what has been accomplished

*Delivered at the annual meeting of the Medical Society of the State of New York at Rochester, April 29, 1913.

since we have had the hardihood to tell a patient that he has tuberculosis; to tell him that by lack of proper care he may transmit the disease to those around him; and to tell him that by careful application of the laws of health he may recover.

There is another phase of the tuberculosis campaign which must be taken advantage of in our fight against cancer; this is the fact that when we give certain knowledge to the public the public gives it back to the medical profession, in those parts of our ranks where it is most needed. I have seen a physician treating his wife who had pneumonia in a room with the window shut. He would not dare treat a woman in a tenement house that way. The tenement house population has been very thoroughly instructed as to the necessity of fresh air. The doctor's wife will learn this when she takes up settlement work and the doctor may learn it from his wife.

The medical profession has learned more about the treatment of tuberculosis since Mr. Wood and other laymen took up the subject than it learned in all the ages prior to that time. I do not mean that these gentlemen have discovered any facts that were not known to the science of medicine, but they have discovered—in the sense of uncovered—some most important facts which were not being employed generally in the practice of medicine.

The scientific investigation of cancer has been going on for many, many years, but so far this disease has withheld many secrets from us. In a scientific way we do not know much more about cancer to-day than we knew fifty years ago. We do not even know its real nature, we do not know its actual cause, we do not know whether it is produced by a bacterium or not. Most of the things which the scientific study of cancer has taught us have been of a negative nature. We have come to the conclusion:

That there is little, if any, reason to consider cancer as being hereditary.

That there is no evidence that cancer as occurring in man is a communicable disease.

That cancer does not produce an immunity as do some diseases.

Scientists have been able to transplant cancers from one animal to another, notably among mice, but these transplantations are not inoculations (as in the case of tuberculosis, for instance). By transplanting these cancers in successive generations of mice we do not produce a family of mice immune to such transplantations; nor do we produce mice immune to spontaneous development of cancer; also we cannot transplant cancers from one animal to another of a distinctly different species, *e.g.* we cannot transplant cancer from mice to guinea pigs, etc., but there have been successful transplantations among species which are nearly akin—as from dog to fox, from rabbit to hare.

The scientific study of cancer has shown us no new cure. Most of the knowledge we have concerning cancer has been gained by clinical observation.

It would not be profitable to expend too much time nor to dwell too long in contemplating or enumerating things we do not know; let us turn our thoughts to things we do know about cancer.

Cancer is not a growth of any extraneous substance or tissue within the body. It consists in a growth of cells which are perfectly natural to the body. These cells are either displaced or misplaced as to their situation and they are abnormal in their arrangement and relationship, one to the oher, but there is nothing abnormal that we can identify as a cancer cell.

We believe that cancer is very much on the increase for some reason or other, and we do not know what this reason is.

We know that cancer is at first a purely localized disease. We know that cancer has a tendency to spread by a natural growth and to develop in and through the lymphatic channels in its neighborhood, and through them to become disseminated throughout the body.

We know that complete removal of a cancer at the time when it is strictly localized and not disseminated will result in cure of that cancer.

We know that incomplete removal of a cancer with its outlying roots will not result in cure, but will result in continuance either at the original site or in some more or less remote part of the body.

We know that in its early stages cancer is localized, in its later stages it is more or less widespread. We know that with complete removal during the early stages or during its localized condition cancer is curable.

While we do not know the actual cause of cancer we do know something of the causation of cancer, for we know that cancer often does result from prolonged irritation, and we know that there are certain conditions which precede or which predispose to the development of cancer. These are known as the precancerous states, or precancerous stages. This is the most important knowledge we have concerning cancer, for by carefully acting upon such knowledge we can prevent, not cure, but prevent, a very large proportion of cancer.

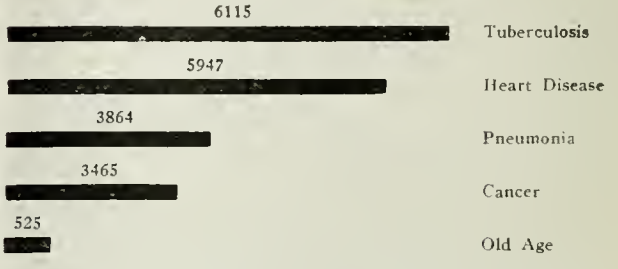
We know that there is no specific cure for cancer, there is no serum and there is no vaccine, and there is no chemical which will act as such.

But we know that a properly executed surgical operation performed at the time when the cancer is still localized will result in cure in a large proportion of cases. And we know that today this is the only reliable method of cure at our command. And we know that by remedying or removing certain abnormal conditions we can prevent a large amount of cancer. In the recognition and in the employment of these two established facts lie our hope. There is a chance for early cure; there is a chance for prevention of this dreadful disease.

Let us pursue our consideration of this subject under several heads.

Diagram Showing Relative Importance of Cancer As a Cause of Deaths In New York City In 1911.

(Between the ages of 30 and 75 years.)



Let us first consider the prevalence of cancer as compared with several other diseases. Then let us touch upon the diagnosis of cancer in certain situations of the body. Then let us consider briefly the relative curability of cancer of certain organs.

Let us give most of our thoughts, however, to the recognition and to the cure of the predisposing causes of cancer, namely, to the precancerous states, and then let us touch briefly upon what has been done for the practical solving of the cancer problem and what further may be done in the way of a successful anti-cancer campaign.

I shall not enter into an elaborate discussion of statistics concerning the prevalence of cancer, but I wish to strongly emphasize the fact that cancer is a very prevalent disease, and that it reaps an enormous harvest of victims every year. Nearly every one who writes upon this subject is agreed that cancer is greatly on the increase. Some claim that cancer is not on the increase, but that it appears to be so because our more recent statistics are based upon a more accurate knowledge and upon a more accurate means of making diagnosis, and that, therefore, we are charging to cancer today numbers of deaths which would have been charged to some other cause during the years when less accuracy was employed. I have made a careful study of many statistical tables and I must say that my mind is in doubt as to whether cancer is really on the increase or not. There is one thing certain, it is not on the decrease, and we have enough of it to make us recognize it as one of the most terrible of scourges. Unfortunately our national and state statistics are of very little value today; we need a national department of health. And we must welcome the time when we have such a department and when we can have thoroughly reliable and intelligent statistics. The analytical study of such statistics is of great value and forms a very important basis for an intelligent comprehension for such a question as to the cancer problem.

I shall set forth simply a few facts which may be gathered from such statistics which we have at hand. Cancer is not a disease of youth; it is exceptional before the twentieth year; it is rare between the twentieth and the thirtieth year. There is a definitely recognized cancerous period of life, namely, from the thirtieth to the seventy-fifth year, the largest number of cases occurring between the forty-fifth and the sixty-fifth year.

TABLE OF DEATHS TAKEN FROM STATISTICS OF DEPARTMENT OF HEALTH, NEW YORK CITY

(Deaths between the ages of 30 to 75 years)

| 1910 | |
|---|---|
| Total number of deaths, men and women | 37,018 |
| Deaths from cancer: | |
| (Women..1,940—5%) | |
| (Men.....1,326—4%) 9% | 3,266 |
| Deaths from tuberculous diseases, 16% | 5,980 |

(Deaths between the ages of 30 to 75 years)

| 1911 | |
|---|---|
| Total number of deaths, men and women | 37,925 |
| Deaths from cancer: | |
| (Women..2,034—5%) | |
| (Men.....1,431—4%) 9% | 3,465 |
| Deaths from tuberculous diseases, 17% | 6,115 |
| pneumonia, 10% | 3,864 |
| heart diseases, 16% | 5,947 |
| old age, 1% | 525 |

Deaths from cancer according to location, between the ages of 30 to 75 years, men and women.

| | 1910 | 1911 |
|---|---|---|
| Cancer of mouth | 123 | 114 |
| stomach, liver | 1,314 | 1,419 |
| intestines, rectum | 529 | 479 |
| female genital organs | 509 | 523 |
| breast | 324 | 339 |
| skin | 46 | 38 |
| other organs, and unspecified | 448 | 553 |
| | 37,018 | 37,925 |

Cancer is more common among women than among men, because the larger proportion of cancer in women is found in the female organs; that is to say, the female genital organs, including the breast. Excluding these (cancers of the genital organs and breast) cancer is more common among men than among women. Cancers of the mouth and of the stomach are more common among men than among women. This is thought to be because men are more addicted to the use of strong drink than are women, and the idea is also based on the assumption that men are more addicted to the habit of smoking than are women—as yet.

Cancers of the bile ducts are more common among women than among men, just as gall stones are more common among women than among men. The relative proportion of the two conditions is very suggestive and instructive, and will be dwelt upon when we come to consider the prevention of cancer. There are remarkably few instances of cancer as an occupational disease, and yet chronic irritation is recognized as a very potent factor in the production of cancer. However, there is the well-known chimney sweeps' cancer, the cancer caused by *x*-rays, the cancer caused by prolonged exposure to the sun, and in this connection we might include the kankri cancer of Thibet.

If chewing betel nuts could be considered as one of the industries of India, we might cite cancer produced by that habit as an occupational disorder.

Unfortunately the use of chewing gum does not produce a rapidly fatal form of malignant disease.

During the cancer period it has been estimated that in England cancer causes the death of one woman in eight and of one man in eleven. In this country cancer ranks next to pneumonia and tuberculosis as a cause among the total number of deaths. The statistics of the Department of Health of New York City for 1911 show the following facts:

After the thirtieth year cancer causes 9 per cent. of deaths; tuberculosis causes 17 per cent. of deaths; pneumonia causes 10 per cent. of deaths; heart disease causes 16 per cent. of deaths; old age causes 1 per cent. of deaths.

It has been estimated that there are between 75,000 and 80,000 deaths from cancer recorded every year in the United States.

There are many more deaths from cancer than are recorded. This is due to faulty diagnosis or inaccurate diagnosis, to neglect to include cancer when some other disease is also present, and to many other reasons unnecessary to dwell upon.

Now we come to the question of diagnosis of cancer. To make a late diagnosis of cancer is of no value whatever, except for the purpose of filling and of making up death lists. What we shall consider and what we should concern ourselves with is the question of early diagnosis. In this connection cancers are to be divided into two groups, namely, the superficial, external or visible, and the deep-seated or internal cancers.

Cancer always presents itself as a tumor or swelling, and when superficially situated it can, of course, be recognized by the two senses, sight and touch. There are some cancers of the skin, notably those of the face and lip, which are very slow in their growth and which consequently do not change rapidly, though they may reach a period later on in their history when a rapid growth takes place. Superficial cancers are to be differentiated from inflammatory swellings, from deformities presenting the appearance of swellings, and from benign tumors. In an address of this character it would not be well nor profitable to attempt to give rules for diagnosis or differentiation. It is

enough that we should call attention to the fact that any swelling may or may not be a cancer, and that it is of the utmost importance that a proper diagnosis be made at the earliest moment, for our only hope of curing cancer lies in an early, radical operation. In this connection the public should have definite but limited knowledge. Laymen and lay women should not diagnosticate their own cases any more than they should treat their own cases, but they should know enough about this subject to insist upon having a thoroughly satisfactory diagnosis from their doctors. As far as superficial cancer is concerned there is no excuse for doubt or error. If the doctor is not satisfied to take the responsibility of his diagnosis he should submit a section of the tumor to a competent pathologist for examination under the microscope.

Now as to the diagnosis of the deep-seated or internal cancers. In this class of cases we have a very different problem to deal with. During the early stages when diagnosis would be of importance and of use in bringing about a cure, a tumor can seldom be detected. The only indication that we may have of an internal or deep-seated cancer may be some disturbance of the function of the organ involved or of some associated organ. Thus any kind of a disturbance of function should lead us to think of the possibility of a new growth, and should lead us to make a most thorough investigation; otherwise, we shall never suspect nor detect internal cancers during the stage when our treatment can be of any avail. Loss of appetite may be the only sign present to indicate an incipient cancer of the stomach. A newly acquired tendency to constipation may be the only symptom of a cancer beginning in the large intestine. Chronic jaundice should always make us suspicious. Loss of weight and loss of vigor not to be accounted for by fever or other apparent cause should always make us apprehensive. Of course cachexia and great emaciation are late signs, and do not concern us unless we are so constituted as to take a lively interest in terminal stages, and unless we are willing to limit our efforts in our patients' behalf to the furnishing of some such terminal facilities as the administation of opium.

*Pain.*—Much valuable time has been lost because of the stress physicians and patients have placed upon the value of pain as a diagnostic sign of cancer. Pain is usually present late. It is present, as a rule, during the late development of cancerous growths. Pain is not a characteristic sign of the early stage of cancer. It occurs early as an exception, not as a rule. It is most important that this fallacy should be dispelled.

This is all that is necessary to be said on the subject of diagnosis until we come to the consideration of special conditions.

There is one thing that cannot be impressed too emphatically, and that is the necessity of early diagnosis. If there is any doubt as to whether a patient is or is not developing a cancer in its early stages, the patient should be given the benefit of that doubt. All suspicious tumors, no matter where situated, should be regarded as malignant until they have been proven to be innocent or nonmalignant.

Take, for instance, a lump or tumor of the breast. Nine-tenths of tumors of the breast are malignant, or become so. An unknown proportion of cases of chronic inflammation of the breast become cancers and any simple or benign tumor of the breast may become cancerous. Unless it be an acute abscess of the breast, every swelling or irregularity of that organ should be regarded with suspicion and should be treated as suspicious.

Now we come to the important question, the curability of cancer. While we know that cancer is a very fatal disease, we also know that by proper means cancer is curable in a proportion of cases. We also know that certain forms or varieties of cancer are much more easily cured than are others, that is to say, that the same means being employed there will be a much larger percentage of cures among one variety of cancer cases than among another variety. This is notably true of such superficial cancers as epitheliomata of the skin, particularly of the face. It is also true that cancer in certain situations of the body varies in this particular. Thus operation of cancer of the colon and of the small intestine yields very good results, while cancer of the lower rectum cannot be so successfully treated. Of course this is very largely determined by the possibilities of early diagnosis, early diagnosis of cancer being much more easy in one situation than in another. And again, this is owing to the fact that a cancer in one situation will produce symptoms much earlier than would the same kind of growth in another region. Wherever the situation and whatever the character of the cancer may be, the proportion to cures will be in direct relation to the period at which diagnosis and treatment have been applied.

Cancer is always a localized disease at first. Operation during the stage of localized growth would mean complete removal of the entire growth and would mean cure in a very large percentage of cases. For instance, in breast cases early operation while the growth is strictly localized will result in 80 per cent. of cures. Later operation with extension but with no axillary involvement may result in 50 per cent. of cures. Still later operation with limited axillary involvement may result in 25 per cent. of cures. Late operation with marked axillary involvement will result in no per cent. of cures.

Progression and dissemination are bound to occur; in fact a cancer growth is progressive from the beginning. After a cancer has made much progress in its growth or has become disseminated from the original focus, complete removal may not be possible; if not, cure will not result.

We now come to the most important part of this address; in fact it is the most important part of all the knowledge we have on the subject of cancer, and that is our recognition of the fact that there are certain conditions and certain diseases which predispose to the formation of cancer. Some of these are so definitely connected with the development of cancer that they are today recognized as and are designated precancerous conditions, or precancerous states.

In 1911, before this society, I had the honor of reading a paper entitled "The Precancerous Stage," in which was set forth the proposition that by studying our cases carefully and by recognizing the fact that certain conditions predispose to cancer, we would be making a great advance in our fight against this deadly foe, for by curing, or removing, these precancerous stages we would be preventing a large proportion of cancer. As far as this is true we see that cancer is a preventable disease.

This is an age of progress, and there should be added to the medical professions a new adage in place of an old one. The old one was "what can't

be cured must be endured." The new one is "what can't be cured must be prevented." Let us now turn our thoughts toward the prevention of cancer.

If cancer is preventable, how can we prevent it? Certainly this can be accomplished only by recognizing the cause of cancer and by doing away with this cause, whatever it may be. Now, as already has been stated, we do not know the real nature of cancer, nor do we know its real cause; but we do know that there are certain conditions which predispose to or determine the development of cancer in a large proportion of cases. Prominent among these conditions are benign tumors, chronic ulceration, chronic inflammation, abnormal tissue such as scars, and prolonged irritation.

*Benign Tumors As a Cause of Cancer.*—It has long been a recognized fact that the majority of benign tumors may sooner or later be invaded by cancer or may undergo cancerous degeneration. This is notably true of most of the various forms of tumors of the breast.

Nearly every variety of benign tumor may be found in the female breast. The fibroadenomata are by far the more frequent, and, therefore, the most important in this connection. These benign tumors may exist as innocent growths for years, and certain of them may continue indefinitely as such; but in the life history of any one of these, carcinomatous infiltration may take place, and then we shall be dealing with a cancer pure and simple.

The lesson to be learned from this is, that every benign tumor of the breast should be removed before it has an opportunity to become carcinomatous. In other words, it should be removed as soon as it is recognized. The time has passed when a doctor, in ignorance, may advise his patient that a tumor of the breast is of no significance unless it shows active signs of malignancy. If we recognize the benign growth as a potential cancer we know at once how to deal with it, and that is, to deal with it at once. In this way we are not only able to insure a patient of definite and permanent cure, but also we may bring this about by means of a small operation involving little shock and the least possible mutilation.

What is true of benign tumors of the breast is true of such tumors in other parts of the body.

*Pigmented Moles.*—Keen, Bloodgood, and, of course, many others, have shown how more than prone these growths are to become cancerous. One of the most instructive lessons can be learned by a careful review of Bloodgood's work in this connection. He made an elaborate study of 65 cases of malignant moles operated upon. In every case the diagnosis was confirmed by microscopic examination. Up to the time of his report there was not a definitely cured case among them. He calls attention to the fact that in every one of his cases the tumor had existed as a benign growth for many years before it became cancerous. Think what this means! It means that 65 cases (the total of a series) became incurable cancers, and that each and every one of these sad cases could have been prevented had operation been performed at the ideal time—that is to say, during the precancerous stage. In the same report he cites 76 cases of benign pigmented moles which were removed in the precancerous stage, and he states that there have been no local recurrences and no deaths from internal metastases.

There has been extensive investigation of this subject in connection with hypertrophy of the prostate. Of course senile hypertrophy of the prostate is purely an inflammatory process, or the result of one. Hugh Young demonstrated an immense proportion of carcinoma among his cases of enlarged prostate. And this fact shows how this chronic inflammatory condition may be the precursor or precancerous stage of the cancer. In his address before the Section on Surgery of the American Medical Association in 1910, Charles Mayo called attention to this fact and cited it as one of the reasons for removing an abnormally enlarged prostate gland.

*Gastric Ulcer and Gallstones As Precancerous States.*—Today we have very accurate knowledge of the lesions of the stomach as compared with what we knew a few years ago. We have the records of vast numbers of cases where the disease has been actually seen and demonstrated by skilled and able pathologists. A few years ago we had to depend on theories and surmises, based on imagination, unaided by sight and demonstration.

While it would be impossible to estimate what proportion of cases of ulcer of the stomach result in cancer, it has been possible to estimate what proportion of cases of cancer of the stomach were preceded by gastric ulcers, either healed or unhealed. In the immense clinic of the Mayos it has been shown that between 60 and 70 per cent. of cancers of the stomach have developed in the site of a pre-existing gastric ulcer, or in the cicatrix of an ulcer which had been healed. In other words, it is evident that we must consider gastric ulcer as the precancerous stage of more than two-thirds of the gastric cancers.

The lesson that we must learn from this is twofold; first, that gastric ulcer must be cured; second, that when we operate for gastric ulcer we must remove the ulcer-bearing area. If these statistics and these statements taken from the Mayo records are accepted, certainly gastroenterostomy is not the logical and rational procedure. It may cure the ulcer but it does not remove the cicatrix of the healed ulceration; in other words, it does not remove what has been pointed out as a conspicuous forerunner of cancer.

Now a word as to the importance of curing gastric ulcers. The day has come when we should insist on cure of all curable gastric ulcers and allied diseases. The day has passed when we should consider chronic indigeston as a man's normal estate. And when we consider the fact that chronic gastric ulcer has been the predecessor of two-thirds of the stomach cancers, we undertake a fearful responsibility in these cases unless we insist upon doing the best that can be done—cure the ulcer—prevent the cancer.

*Gallstones.*—Let me cite an illustrative case. Unfortunately it is an example of a very common occurrence. A patient was referred to a surgeon for an operation on account of an obstructive jaundice. It was evident to the surgeon that the patient probably had a carcinoma. And it was with that understanding that he performed an exploratory laparotomy. The reasons for this diagnosis of probable cancer were continuous jaundice, progressive emaciation and loss of strength, and absence of febrile disturbance. There were also present vomiting and other gastric symptoms which indicated obstruction at the pyloric outlet. On opening the abdomen it was found that the patient had a carcinoma, involving the gall bladder, the greater omentum, the transverse colon, the lower

end of the stomach, and, in, fact, all the organs in that region.

The patient gave a clear, distinct, and classic history of gallstone disease, lasting over a period of more than eight years. Of course the carcinoma did not last that long. From her history it was evident that it was of comparatively recent origin.

The above case is only one of innumerable instances which can be cited. It clearly depicts a case of cancer which had a very distinct precancerous stage, and there is little doubt that an operation performed years ago curing this patient of gallstones would have prevented the development of cancer.

That gallstones cause cancer there can be little doubt. In practically 100 per cent. of cases of primary cancer of the gall bladder and bile ducts gallstones may be found, and it may be demonstrated that they have existed for a long period before a cancer developed. It has been asserted that these cancers never develop except when preceded by gallstones.

It may be assumed that no case of gallstone disease recovers spontaneously. Of course a large proportion of gallstone cases may exist for years without showing violent or active symptoms. The fact that cancer results from long irritation of gallstones should demand an operation in every case, unless the patient's condition is such as to outweigh the reasons for operation. There are many other reasons why gallstones should not be left unoperated upon. Gallstones are never a benefit to the patient; they are always a source of harm. It is not necessary to discuss this point more fully in this connection. For our present purpose this one fact is sufficient—gallstones are invariably precursors or forerunners of biliary cancers, and for that reason if for no other we should operate and cure all cases of gallstone.

*Chronic Irritation As a Cause of Cancer.*—In the mountains of Thibet the natives are in the habit of carrying a small stove like a pocket stove in one part of their tunics. This stove is called the kankri. The polonged use of this kankri stove is followed by cancer at the site which is irritated by the heat. A very familiar example of cancer caused by irritation is the so-called clay-pipe cancer of the lip, caused by the habitual use of the clay pipe. Another is, or rather was, the chimney sweep cancer, caused by the irritation of soot lodged in certain folds of the skin. In late years we have added to our list the cancers produced by the too frequent exposure to the *x*-rays. A sharp tooth, by prolonged irritation, may cause a cancer of the lip or tongue. In India some of the natives are in the habit of chewing the betel nut, and they even go to sleep with a betel nut lodged in their mouths. At the place where this betel nut causes chronic irriation cancers develop. In China the men are in the habit of eating very hot rice. Owing to their inferior social status in that country Chinese women have to wait and do not get their rice fresh from the fire. Cancer of the stomach is very much more common among the Chinese men than among the Chinese women. By some this fact is ascribed to the difference in the temperature of the rice they eat. The social elevation of Chinese women may result in their not only sharing equally with the Chinese man in his vote franchise but also in his gastric cancer. Gallstones causing cancer form an illustration of the effect of chronic irritation. We might multiply these instances indefinitely. I believe the examples just given are sufficient to show that cancer does result from prolonged irritation.

The lesson to be drawn from this is obvious, namely, to avoid prolonged irritation. *X*-ray operators must protect themselves. A proper attention to a sharp tooth may be a means of preventing a cancer of the tongue. In a word, we should learn to avoid all unnecessary prolonged irritation, especially those forms of it which are known to result in the production of cancer.

*Chronic Inflammation As a Cause of Cancer.*—We frequently see examples of this condition. There is one form of chronic inflammation which might not be recognized as such, certainly by the laity. The best example of this form of inflammation of which I speak is found in the female breast. It is sometimes spoken of as abnormal involution of the breast. It is characterized by irregular hard masses within the breast which are not distinct tumors. This particular form of chronic inflammation of the breast is very liable to become invaded by cancer, so much so that it may be considered a precancerous stage, and it should be treated as such. If left to take its course many a cancer will ensue; if properly removed by an early surgical operation many a cancer will be prevented. This condition bears a strong analogy, both in its history and in its microscopic findings, to the change which takes place in the prostate gland, resulting in prostatic hypertrophy, and which in the prostate results in carcinoma in a very large percentage of cases.

I have not spoken of cancer of the uterus, nor do I believe it is necessary to dwell long upon that subject in this address. Uterine cancer is among the most frequent of all forms, and unfortunately it is among the most fatal. Cure of uterine cancer is very difficult. Our greatest hope lies in prevention. There are many conditions which predispose to these cancers, such as simple tumors of the uterus, chronic inflammation of the organ, and chronic ulceration, or so-called erosion, usually the result of neglected laceration and tears. All these abnormalities should be remedied because they are precursors of cancer. They are precancerous conditions. Of the symptoms I shall not speak at this time.

Now let us take unto ourselves such lessons as can be taught from the foregoing statement. Let us see whether we have been doing our duty in the past and let us see what we can do in making a fight against this dread disease in the future.

We may sum up our facts very briefly. Cancer is a purely localized condition at first. It tends to spread and to disseminate so that it soon ceases to be localized. Cancer can be cured only by complete removal of the entire growth. The entire growth can be removed only before dissemination has taken place, namely, in the early stages. Therefore, in early operation lies our only hope of curing cancer.

Have we been operating on our cancers in the early stages? We have not. A careful study of a large series of cases by the Pennsylvania Cancer Commission brought out the fact that on an average one year and two months elapsed between the time when cancer was first detected and when it was operated upon. It brought out the further fact that one year elapsed on an average between the time when a physician first examined the case and when operation was performed. Less than 68 per cent. of superficial cancers and less than 48 per cent. of

deep-seated cancers are operable when the patients come to the surgeons. Think of this delay! When we realize the fact delay amounts to death, it certainly behooves us to see if we cannot do better in the future.

I must mention some other facts which were brought out by this investigation, namely, that in about 10 per cent. of cases the physician first appealed to made no examination, and that in between 10 and 20 per cent. of cases which were examined the physicians gave mal advice, such as, "Let us wait and see what happens"; "Do not bother about it unless it becomes painful," etc.

Of course we cannot attain the ideal, but we should certainly strive to come as near it as possible, and if we do not examine our patients when they come to us, and if we do not advise them along the lines of well-established fact, we certainly are not striving after the ideal, we certainly are not doing our best.

Undoubtedly the patient is more often at fault than the doctor, but that does not excuse the doctor for his errors, and it certainly behooves every one of us to do all we can to educate the public in these important questions and to stimulate them and to encourage them to cooperate with us.

There is one important thing which must not be forgotten and which must be impressed upon the public, and that is the fact that surgical operations performed by skilled surgeons entail very little risk of life. Such operations as are performed for the early cure of cancer certainly do not result in the death of 1 per cent. of patients. Late operations must necessarily be more extensive, more severe, and more dangerous.

Now let us see what may be said as to the cure of those conditions which may be considered precancerous stages.

This takes us into a very wide field. It is almost a plea for good health. Here the physician and the patient must cooperate; neither must be satisfied with anything short of perfection, as far as perfection can be brought about. Just consider for a few moments the question of digestion and indigestion. Digestion is a normal function which should be carried on without symptoms, without discomfort. Indigestion is a symptom; it means a disturbed function. Of course it may be indicative of a purely functional disorder, but structure and function are so closely associated that an abnormal function should prompt us to suspect and to look for a structurally diseased organ. Now wherein may indigestion be a warning of a cancer yet unformed? Indigestion and dyspepsia may be the manifestation of gallstones, or of a gastric ulcer. Gallstones cause 100 per cent. of cancers of the gall bladder. If we could cure all cases of gallstones and if we could cure and remove all gastric ulcers before cancers have resulted therefrom, we would have no case of primary cancer of the gall bladder, or of the bile ducts, and we would have but one-third as many cancers of the stomach we have now. It has been roughly estimated that nearly one-half of cancers have a very easily recognized precancerous stage. If these precancerous stages bear the relationship which we think they do to cancer, their cure or removal would mean the doing away with practically one-half of the cancer.

I feel that this topic on which I have addressed you is a very timely one. It is belated, rather than timely, as far as its importance is concerned, for we should have given it more attention long ago. It is timely, because we are beginning to make an organized fight upon cancer, very much as we are making an organized fight against tuberculosis. To accomplish this we must make every endeavor to raise the standard of work among the physicians. As I said in the beginning, the greatest necessity lies in raising the average; our average is too low. We should give every possible encouragement to the scientific study and investigation of cancer. By that means the solution of the problem may be found some day, but at present it behooves us to better our work in everyday practice, to see that we disseminate among our entire profession all the practical knowledge we have, and to endeavor to bring it about that all our knowledge shall be employed all the time, by all of our profession.

Now as to the enlightenment of the public in these matters. I hold with the majority of our profession that it is very important that the public should have increased knowledge of this subject, but I do believe that we should be very guarded in the kind of knowledge we teach. We cannot and we should not teach the public the symptoms of cancer. We must be careful not to fill the public with unwarranted apprehension of cancer. Most of our teaching must come through the physician in his practice. If that were well done it would be far better than anything we could do in the way of spreading knowledge by literature. But there are some things which it is well for the public to know. It is well for them to know that every lump and every swelling is more or less suspicious. They should know that cancer has no definite characteristic symptom which distinguishes it from other conditions; they should know that a physician can give intelligent advice only after he has made a most careful examination in any case. They should not receive nor act upon any advice that is carelessly given. They should know the significance of indigestion, they should know the importance of good health, and they should know that cancer is in a sense preventable, and that it is in a degree curable, the degree in which it is curable depending entirely upon the time in which it is removed. They must know that operation in skilled hands is almost free from danger, that operations are safe, that delay is the chief danger in cancer.

The campaign against cancer has fairly begun. It has already been taken up actively in several States; in some by the health departments, and in others by commissions appointed by State medical societies. Such a commission was recently appointed by the Clinical Congress of Surgeons of North America. The American Medical Association and several of its affiliated State medical societies have started on active work.

In this connection I am not speaking of the tremendous work which is being done by various institutions and foundations along the line of the study and investigation of cancer as a problem: I am speaking of the campaign of enlightenment and of publicity which has been started along the more practical lines.

Of course this is not only a humane problem. It is a most important social and economic problem. If a well-organized campaign can result in reducing the morbidity as well as the mortality resulting from cancer, think what a saving it will be to the State.

How directly this thought can be applied to life insurance companies. If life insurance companies can do anything that shall lessen the number of

cancer cases developing among their policyholders, how much money may be saved to them. Some insurance companies are showing a recognition of this fact and are doing much in the way of disseminating knowledge among their policyholders, not only concerning general hygiene and preventive medicine, but some of them are trying to impart just such knowledge as I have spoken of, namely, knowledge as to how to prevent cancer.

This campaign should not only be nation wide, but world wide; and the more quickly it is started on a uniform basis with good organization the more quickly will it become effective. If we can have this matter taken up as a national affair with systematic work done throughout the United States, with every State and every county working under a uniform plan, how much may be accomplished. One of the first necessities is the establishment of a national department of health, whereby we can unify our proceedings, and whereby there can be issued national statistics which will be complete and accurate.

Think how much we may accomplish by a successful campaign of uniform and unified effort. When no longer fourteen months ensue between the first discovery of a cancer—and its final surgical treatment, and when no longer a year is to be lost between the time the physician first meets a cancer and the time when the cancer is brought to operation, and when no longer the physician who is first consulted in a case of cancer gives mal advice, and when physicians and patients recognize the fact that in early operation lies our chance of cure, think how many less deaths there will be from cancer.

If it is true that 50 per cent. of cancers show a definite and easily recognized precancerous stage, and if it is true that there are 80,000 deaths from cancer in the United States annually, then the remedy of the precancerous state, and the prevention of cancer will save 40,000 of our citizens annually from this terrible scourge. We may not attain our ideal, but let us unite our efforts to do the best that can be done.

540 Park Avenue.

## THE SURGICAL TREATMENT OF CANCER OF THE ESOPHAGUS.*

By WILLY MEYER, M.D.,

NEW YORK.

ATTENDING SURGEON GERMAN AND POST GRADUATE HOSPITALS.

The subject assigned to me in this symposium, "The Surgical Treatment of Cancer of the Esophagus," does not necessarily imply that I am to talk on surgical details. I propose to take a broader view of the matter and consider briefly the division of responsibility between family physician and surgeon in the task of saving the life of patients afflicted with cancer of the esophagus.

Naturally the question arising in the mind of every physician is: What results have the surgeons to show us; have they saved any patients with malignant disease of the thoracic portion of the esophagus by operating upon them?

The surgeon may rightly turn around and ask: Can the physician give such a patient any hope whatever that he may pull through without operation? Can he conscientiously tell the patient's relatives anything else than that within twelve to fifteen months, more or less, the patient will surely be dead and will probably have died a most horrible death? In other words, can he say anything else than that the mortality of the disease with which the patient is afflicted is 100 per cent? He certainly cannot.

If, on the other hand, the question is put to the surgeon: Can you give a patient suffering from cancer of the esophagus a ray of hope? the surgeon can today reply confidently and conscientiously: Yes, I can. Yes, gentlemen, entrust to the surgeon a patient before he is past all hope; turn the patient over to him before the disease has had time to spread beyond the wall of the esophagus, before it has taken hold of adjacent organs, and, above all, before it has spread to both pneumogastric nerves, let the surgeon get the patient before he has wasted away in strength and weight; and if you can and will do this, gentlemen, the patient certainly has a chance.

The time when the surgeon should receive this class of patients is when you have become convinced, nay suspicious, that he is afflicted with cancer of the esophagus. At that moment he is past help from the general practitioner. From that moment on, if the patient be willing to submit to surgical intervention, there can be no further justification for general treatment.

The question of how to arrive at the conviction that one is dealing with a cancer of the esophagus—how to diagnose such cases—has been dwelt upon at length by the preceding speakers. I wish to emphasize only this one point: If a patient comes to you and complains of difficulty in swallowing, do not temporize with him. Subject him at once to a most rigid examination, and if you have excluded cardiospasm or the presence of a diverticulum; if you have excluded pressure upon the esophagus from without by an aneurysm or by glands or by a mediastinal tumor; if you have excluded a cicatricial stricture, also a benign stenosis following the rather rarer affections of a tuberculous or specific ulceration or a peptic ulcer at the cardia; I say, if you have been able to exclude all these possible causes for the difficulty in swallowing, as you will be in nearly 80 per cent. of these cases, then, gentlemen, you have a patient before you who is marked with the sign of death. Do not temporize with such a patient, and if the diagnosis be "cancer of the esophagus," turn him over to the surgeon at once, for only in the *early stages* of this disease has the patient a real chance of being saved by the knife.

You will want to know now, of course, what makes me speak so confidently; what right I have to come before you and demand the delivery of this type of patients to the care of the surgeon. There are several reasons.

The first one is the general nature of the disease. In the beginning it is slow of growth and slow in forming metastases. In most cases it starts one-sided, similar to a cancer of the rectum, and only gradually involves the pneumogastric nerve, which, you will remember, runs alongside and close to the esophagus on the right and left from a place immediately below the aortic arch down to the diaphragm. The disease is as yet localized within the esophagus and remains so sufficiently long, if detected early, to cover the unavoidable loss of time in determining the diagnosis and carrying out the necessary operative work preceding the extirpation (gastrostomy).

[1] Read before the Harlem Medical Association, March 5, 1913, being part of a "Symposium on Cancer of the Esophagus."

In short, the first reason is that in the early stage of the disease, cancer of the esophagus is ordinarily almost a benign growth and can be extirpated radically. I am, of course, speaking of the average case, and I know very well that many a patient of this type calls on the physician for the first time when a typical circular stricture has already formed; that means, he calls when the disease is in an advanced stage. But even then the patient should be turned over to the surgeon at once. Let *the surgeon* decide whether an operation on the esophagus should still be resorted to.

The second reason is that with the methods now at hand and the experience gained through persistent surgical effort since 1904, we can at present state, weighing our words carefully, that under favorable circumstances the patient may live.

The third reason is that the absence of successes in the surgery of cancer of the esophagus up to the present time is to a great extent due to the fact that to my knowledge no surgeon has yet had a chance to operate upon a case under really favorable circumstances.

Let me repeat then once more: A patient who has difficulty in swallowing is a serious case, needing immediate and most thorough attention. If with all the diagnostic means at command a definite diagnosis cannot be made, but the probabilities *are for cancer,* then the patient should be turned over to the surgeon for an exploratory thoracotomy. Statistics show that exploratory thoracotomy is as safe as exploratory laparotomy and should, therefore, be resorted to without hesitancy, where indicated. Then, if the diagnosis of cancer proves correct, the surgeon should be prepared to proceed immediately on proper lines.

Assuming now, for the sake of argument, that the patient had reached the surgeon in a condition which left a chance for successful surgery, that the operation had been successful, and that under present improved and tried methods of after-treatment the patient had recovered from the operation, in what condition is he left then? Is he left in a condition that will make it worth while for him to live on, or will his condition be such that, after all, it would have been better for him to have died without operation? Here it becomes necessary to enter into some surgical detail.

Our lately developed operative method of choice makes for gastrostomy use of Jianu's new operation, in which a part of the major curvature of the stomach is dissected and formed into a long, gut-like tube. One end of the same remains connected with, and opens into, what is left of the stomach; the other end is free.* Of this gut-like tube we now make use for the reconstruction of the esophagus.

In cases in which the examination demonstrates a location of the carcinoma above, behind or right below the aortic arch, the newly formed tube is drawn up extrathoracically, below the skin or pectoral muscle to a point next to or above the mammary gland (Jianu) and at a second sitting, after resection, the oral end of the esophagus having also been transposed extrathoracically (v. Mikulicz, Kelling, Ach) the connection between mouth and stomach can be completely restored, either directly by end-to-end suture, or by a subsequent plastic operation (extrathoracic esophagoplasty).

*A female patient, 46 years old, who had been operated on at the German Hospital with gastrostomy according to Jianu's method on December 26, 1912, was presented at the meeting. The gastrostomy opening is at the level of the cartilage of the third left rib.

In cases in which examination demonstrates the presence of the carcinoma in the lower third of the esophagus, or localized at the cardia, it has been, with that condition assumed, my recent practice in animal experimentation, to transpose the tube intrathoracically through the esophageal foramen of the diaphragm alongside the cardia, which had been closed by sutures and during the resection and to bring it to a connection with the undisturbed oral end of the esophagus, by end-to-end suture (intrathoracic esophagoplasty).

Both these methods have their advantages and also, for the time being, at least, their disadvantages. Intrathoracic esophagoplasty would functionally restore the patient to where he was before the cancer attacked him. From this point of view the method is certainly ideal. But, as far as can be stated at the present moment, the operation will, in all probability, have to be done in one sitting.

Extrathoracic esophagoplasty, on the other hand, is, by its nature, a two-stage operation; but we do not know yet what length transposed oral end of esophagus will live.*

Should further experience prove that the oral end of the esophagus, however long, can be safely transposed and united with the tube brought up from the stomach, then extrathoracic esophagoplasty would be the operation of choice, no matter where the cancer be located, unless a way be found to do the intrathoracic esophagoplasty in two stages.

This is a rather brief sketch of the present day evolution of the surgical aspects of the matter under consideration, but I hope it has been sufficient to make you feel that in view of the inevitable death under palliative treatment, surgical treatment with its ray of hope is the preferable procedure.

In conclusion I wish to say: Where diagnosis can be made and operation done in the early stages of cancer of the thoracic part of the esophagus, surgeons are justified at present in advising radical intervention.

In order to bring about the conditions necessary for a favorable prognosis, patients complaining of difficulty in deglutition must not be treated expectantly.

*Note.*—This paper was read on March 5. Nine days later, on March 14, Dr. F. Torek, attending surgeon to the German Hospital of New York, removed a cancer of the esophagus, situated behind the aortic arch, in a woman of 67 years. The cancer was in the early stage and both pneumogastrics could be well dissected off. The patient recovered. At the same time the March issue of the *Beitraege zur klinischen Chirurgie,* Vol. 83, 2, was received. In it Dr. J. H. Zaaijer, first assistant at the Surgical Clinic of Leiden, Holland, reported a successful case of carcinoma (also in the early stage) which involved the lower portion of the esophagus. The operation was performed on Jan. 9, 1913: The two first successful cases of resection of the esophagus for carcinoma, with entire recovery of the patients.

The experiences prove that there *is* hope of recovery after resection of the esophagus, provided the disease can be attacked at an early stage; and in view of the known comparatively benign character of cancer of the esophagus, the chances of a permanent cure in such cases are certainly good.

*It is of the greatest importance for the patient's future that partial gangrene with the ever-occurring subsequent phlegmon of the surrounding tissues should not set in. If a phlegmon does occur, it will seriously interfere with future skin-plasty, indeed it may render it impossible altogether.

# THE PURIFICATION OF NEW YORK HARBOR.

By GEORGE A. SOPER, Ph.D., M. Am. Soc. C.E.,

NEW YORK.

PRESIDENT, METROPOLITAN SEWERAGE COMMISSION.

Attention was first called to the necessity of making comprehensive plans for the disposal of the sewage of the metropolitan territory when the New York Bay Pollution Commission made its report in 1905. The Pollution Commission had been created to study the effect which the proposed Passaic Valley trunk sewer of New Jersey was likely to have upon the waters of New York bay, and its investigations brought to light conditions which called imperatively for remedy.

The remedy, however, was not easy to find. The great cost of such works as would apparently be required made it necessary to proceed with caution. It was evident that a good deal of sewage was being disposed of by the harbor waters, but the circumstances under which it disappeared were not fully understood. It was considered desirable that the whole question of sewerage and sewage disposal in the metropolitan district should be made the subject of investigation by a qualified body.

## OFFICIAL STATUS OF THE INVESTIGATION

It was in accordance with the recommendation of the Pollution Commission, and on the initiative of the Chamber of Commerce of the State of New York, the Merchants' Association, the Board of Trade and Transportation, the Produce Exchange and the Maritime Association, which, together, represent all the trade and commerce of this port, that the Legislature passed a bill in 1906, requiring the City of New York to appoint the Metropolitan Sewerage Commission and authorizing the city to raise such money as might be necessary for its work.

The State gave its authority for the investigation, conferring upon the commission all the powers of legislative bodies, including the right to enter upon property, subpoena witnesses and administer oaths. The State specified the subjects which were to be studied and required that three at least of the five members should be of recognized skill in sanitary engineering. No power to construct or to compel the construction of works or to require the adoption of any of its recommendations or plans was given to the commission. It was to be essentially and solely an investigating and advisory body. It has remained such to the present time without any intention or desire for change. The work for which it was created is rapidly drawing to a close.

The area studied by the commission covered about 700 square miles. The present population was about 6,000,000 and the future population for whose wastes preparation had to be made was about twice this figure. There were over 100 cities and towns in the district and the quantity of sewage produced was about 765,000,000 gallons per twenty-four hours. In 30 years or so this quantity would be nearly doubled, but the harbor water available for carrying the waste away would not increase.

## SCOPE OF THE STUDIES.

The commission was required to examine the extent and condition of the sewers, as well as to investigate the state of the water into which the sewers were intended to discharge. It was necessary to study the conditions produced with reference to public health and welfare, by which was meant specific harm to health and nuisance from smell and offenses to the sense of sight. The commission was required to consider injury to property as, for example, to the fishing interests, to vessels and to real estate.

A knowledge had to be obtained of the tidal phenomena which were opposed to the prompt removal and disposal of the sewage and those which could possibly be employed under proper circumstances to carry the sewage away. When it was discovered that the tidal actions were unfavorable to the inoffensive disposal of the sewage and that the water possessed a certain capacity for harmlessly and inoffensively assimilating organic matters, it became necessary to study this capacity and how it could be turned to good account.

The commission was not free to design works for the purification of the harbor without regard to cost nor without respect to the peculiar governmental conditions under which the works would have to be built and maintained. The sewers and the harbor waters were located within the limits of many cities, in two states and, in some respects, under national control. In other respects no control whatever existed.

In brief, the commission was required to ascertain the facts, formulate the remedy and devise the means by which the remedy should be applied. It was essential that the remedy should be necessary and sufficient for the present and capable of extension in order to meet the more exacting requirements of the future.

The work was to be done with such thoroughness as to set permanently at rest all speculation concerning the conditions of pollution and the remedies required. In the employment of assistants, in the purchase of supplies and in other respects, the commission was required to follow the machinery which had been devised by the city for the regulation of the great city departments. The Commissioners were to receive a yearly compensation of $3,000 in lieu of their personal expenses.

## DATA COLLECTED AND REPORTS.

During the five years that the commission has been organized in its present form a large amount of work has been done and much of this work has been described in printed reports. These reports, ten in number, have been distributed to city officials and the principal libraries. But very little knowledge of the commission or its work has come to the attention of the general public. The explanation of this probably lies in the fact that the commission has had nothing to promote, no argument to make, no project to foster. The reports are made to the Mayor, and although usually given to the press, the newspapers seem not to find the subject of interest.

Two of the commission's reports are bound volumes of quarto size and together contain about 1,000 pages of tables, maps and explanatory matter relating to the conditions of sewerage and sewage disposal which exist at the present time, and the principles under which the sewage should be collected and disposed of in future.

*Read at a meeting of the New York Academy of Medicine, March 20, 1913.

In a series of five reports, soon to be increased to seven, the commission has outlined the results of the plans it has made for the public works which it will be necessary to construct to protect the harbor against excessive pollution. One of the forthcoming reports will describe the works which the commission recommends for Manhattan and Brooklyn and the other will contain expert criticisms of these plans.

A third bound volume, comparable with the first two in size, is being prepared and will contain the results of numerous experiments on the purification of sewage, and other material of a constructive nature.

The amount of work done has been far in excess of what was expected, owing to the complex character of the problem and to the fact that practically all the information required had to be gathered at first hand.

### SUMMARY OF THE ASCERTAINED FACTS.

Briefly stated, the commission has found that the methods by which sewage is disposed of in the metropolitan district of New York and New Jersey call for immediate and far-reaching improvement. The problem of disposing of the sewage of this territory has taken on a new aspect in recent years, owing to the large increase of population which has occurred. The present conditions, bad as they are, serve as a warning of still worse conditions which will certainly occur if radical measures are not soon adopted to prevent them.

The waters within 15 miles of Manhattan Island which formerly were of ample capacity to receive and dispose of the sewage which was discharged into them are rapidly becoming over-burdened with the wastes. Sewage is not discharged anywhere within 20 miles of the New York City Hall today without creating a nuisance, or serious risk of nuisance. Bathing in the waters of New York harbor above the Narrows is dangerous to health and the oyster industry, already driven to the outer limits of the district, must soon be entirely given up. There are parts of the harbor where the water is discolored and rendered turbid with visible sewage matters for many acres.

Not only does the discharge of sewage now produce objectionable conditions near the points of outfall, but the waters which flow in the main channels of the harbor above the Narrows and in the lower East and Hudson rivers are more polluted than considerations of public health and welfare should allow. It has been proved that, contrary to popular belief, the tidal currents do not flush out the harbor satisfactorily, but cause the sewage to oscillate back and forth near its points of origin.

In addition to the objectionable conditions produced by the discharge of sewage from the cities immediately surrounding the harbor, a number of extensive trunk sewerage projects are being constructed to carry the sewage of inland municipalities for disposal into the waters in the immediate vicinity of the city of New York. These trunk sewers ultimately will add greatly to the polluting matter entering the harbor, unless prevented from doing so. The total capacity of the trunk sewers now built or under construction is 700,000,000 gallons of sewage per day. By the time these sewers have arrived at their full capacity the quantity of sewage from the City of New York will be at least twice what it is now, or over 1,000,000,000 gallons per twenty-four hours. It should be unnecessary to sound a clearer warning of the future condition of the harbor than these facts indicate.

### PROPOSED REMEDIES.

In general, the remedy proposed by the commission is to permit as much sewage to be discharged into the harbor as considerations of public health and welfare permit, and to keep the rest out by means of intercepting sewers, purification works and pumping plants. For the most part, the intercepting sewers will run along the shore lines and gather into them the sewage which is collected by the common sewers from the streets and houses. The interceptors will lead to centrally located points, where much of the organic material contained in the sewage will be removed or from which the sewage can be pumped to distant places for disposal.

Owing to the density of population and to the high cost of land, it will not be practicable to locate efficient purification works in all situations in which they are desirable. The most efficient processes which can be installed on Manhattan Island or its immediate vicinity are such as employ screens and grit chambers. The more effective biological processes, including filters and oxidizing beds, require so much land and produce so much odor and trouble from flies that they cannot be installed anywhere within the metropolitan district, except under special and unusual conditions.

To relieve the harbor of such part of its burden of pollution as will be required, it will be necessary to carry a large part of the sewage to the ocean and there construct an island where the sewage can be partly purified before it is discharged. It will be necessary to construct an island and to treat the sewage before emptying it into the surrounding waters for the reason that a suitable outlet for the great volume of raw sewage to be dealt with cannot be constructed far enough from shore to make certain that the sewage materials discharged there will not return and pollute the beaches. Men cannot live under the great pressure of air which would be necessary if a tunnel were to be built far enough at sea to prevent the crude sewage solids from coming back.

### A SEWAGE ISLAND.

The commission recommends that, to begin with, 203,000,000 gallons of sewage, during periods of dry weather, shall be collected from the territory naturally draining to the lower East river and pumped to an island to be located on a natural sand bar about midway between Sandy Hook and Rockaway Point. From the proposed site the shortest distance to land is about 3 miles. The sewage will be discharged after two hours' settlement, during which the suspended matter will have an opportunity to deposit in tanks from which the solids will be frequently removed and shipped to sea in a special tank steamer.

Responsibility for the sewage will not cease when the effluent leaves the island and this project does not contemplate the removal of nuisance from one place to another. The final disappearance of all sewage matters which leave the island will occur through the natural digestive capacity of the water which, at this place, is practically 100 per cent. normal.

The preliminary estimates which have been made indicate that the cost of constructing the island, which will be about twenty acres in extent, building the tunnel, pumping station and sewers will be less than $20,000,000.

This is the beginning. Ultimately the works will have to be extended, the general plan being to afford, by means of complete removal from the inner harbor, that relief from sewage pollution which the waters are not able properly to bear.

### A STANDARD OF CLEANNESS.

As a guide in determining the extent to which the harbor waters may be used for the assimilation of sewage, the commission has drawn up a set of regulations, which it has called a standard of cleanness, or limit of permissible pollution. Such questions are not determinable with the accuracy and definiteness of chemical analysis; they are largely matters of opinion and the standard of cleanness for New York harbor has been treated as such by the commission. It is obvious that the water need not, and cannot, be kept as pure as would be necessary if it were to be used as a source of drinking water. On the other hand, it will remain a great asset for health, convenience and comfort, only so long as it is, and appears to be, free from excessive contamination.

After it had formulated its own opinion as to the proper terms of a standard, the commission called upon eight eminent sanitary experts to inquire into the situation and express, without reference to the work of others, their own opinions. The same questions were asked of each and each was given the same opportunities for study. The reports covered much the same ground, but the points of view from which the subjects were considered were, as was expected, quite different. One of the experts was a civil engineer; another a chemist; a third a state health officer; a fourth an authority on the transmission of communicable diseases; a fifth was a biologist; a sixth was an expert in sewage disposal; a seventh was a teacher of hygiene and the eighth was a scientist who had made a special study of the disposal of sewage through dilution with tidal waters.

It may be said, therefore, that the question of a suitable standard of cleanness for the waters of New York was regarded from every important point of view. The standard which the commission has proposed consequently bears not only such authority as the members of the commission possess, but the additional weight of these sanitary experts. All of these reports, with a comparison and digest of the same, have been published in full by the commission.

The standard requires that solid matters, recognizable to the senses as of sewage origin, shall not be visible anywhere in the harbor; that the water shall not be rendered greasy or turbid or discolored by sewage, and that gases due to the discharge of sewage shall not occur. There shall be no deposits of sewage matters injurious to navigation, and the oxygen in the main tidal channels shall not be permitted to fall below about 58 per cent. of its saturation value during the warm summer months. So far as bacterial purity is concerned, it was not thought desirable to specify the number of bacteria or the kinds permissible in the inner harbor, such a standard being likely to prove unreliable in the present state of biological science. Bathing and the taking of shellfish for food should not be permitted in the city north of the Narrows, except under special circumstances and conditions, and the water at bathing beaches and over shellfish beds should correspond, bacterially, to drinking-water requirements.

### DESIRABILITY OF JOINT STATE ACTION.

In order to carry out the recommendations of the commission there will be need of new laws and a new central board or commission to interpret and enforce the standard of cleanness which has been proposed and perhaps construct and maintain the engineering works which will be necessary.

The commission has advised that a permanent supervisory body should be appointed by New York and New Jersey or, in other words, a joint interstate commission. This commission would be established by acts of the Legislatures and confirmed by Congress. If this joint action cannot be brought about, or if it is not considered feasible at the present time, the duty of carrying out the policy of conservancy should be placed in the hands of a commission for the metropolitan territory of New York, the expectation being that New Jersey will later create a similar commission to cooperate with it in the interest of the common welfare.

Existing departments and provisions of government cannot appropriately nor adequately deal with this question. The problems to be confronted are of unusual difficulty and complexity, owing to the great extent of territory, the large population and the many hydrographic, sanitary and economic questions which must be considered and adjusted from time to time in the several localities concerned. There will be much work to be done by the local authorities in fitting their sewerage systems to the main drainage and disposal works.

Finally, it is a pleasure to record the fact that the commission has received during its investigations the cooperation of many departments and bureaus of the Municipal, State and National Governments. It has had the cordial endorsement of two city administrations of New York and the appropriations of money which have been made for the work have always been in accordance with the commission's own estimates of its needs.

17 Battery Place.

## CANCER OF THE UTERUS.*

By REGINALD M. RAWLS, M.D.,

NEW YORK,

ASSISTANT SURGEON WOMAN'S HOSPITAL, GYNECOLOGIST NORTHWESTERN DISPENSARY.

The study of cancer became an "exact experimental science" in 1889 when Hanau[1] and Morau[2] and in 1901 when Jensen[3] and Loeb[4] demonstrated that carcinoma and sarcoma of white mice and rats could be transplanted into other animals. The total life of these animals is only about three years, and thus in a comparatively short time we are able to study cancer through many generations. In 1886, with the establishment of the first Cancer Research Fund, and since that time, with the establishment of many others throughout the land, it has been possible to accumulate much valuable information in regard to animal cancer. In one laboratory alone they now have under study sixty varieties of cancer. The recent work of Carrel[5] and his associates of keeping human cells alive outside of the body will unquestionably be of much service in the further work on cancer. While as yet these experiments have thrown very little light on the cause and cure of human cancer, yet we now have the prophecy that a specific will be found even before its etiology is understood.

*Read before the West End Medical Society, November 23, 1912.

From a review of the statistics of all countries, with reliable records, we find that cancer as a whole is on the increase. This is especially true of the digestive tract, with the exception of the mouth, whereas on the other hand carcinoma of the female genital tract is remaining stationary, or in some instances it is slightly on the decrease. Werner[6] has studied the statistics of Baden for the last twenty-five years, and finds that the yearly death rate from cancer has increased one-third. In persons over sixty years of age the increase is 50 to 60 per cent., from 40 to 60 years of age the increase is very slight, and in the very young there is no increase. He does not believe that the increase, as a whole, is due to better diagnosis, more hygienic conditions, or more careful records, for if it was it would affect all ages indifferently. Bertillion[7] thinks that the increase for all countries has doubled in the last thirty years. T. S. Brown[8] states that the death rate in Germany has increased seven times in the last thirty-three years, in Boston three times in thirty-two years, and in New York twice in eleven years. Kampermann[9] reports that in Michigan during the five year period ending December 31, 1909, the mortality of cancer has increased 15 per cent. In his study of 5,300 patients, practically all suffering from gynecological complaints, who in the last ten years have applied for treatment in the University of Michigan Gynecological Clinic and in the private hospital of Dr. Reuben Peterson, he found 212 had some form of uterine cancer. Thus he thinks it is fair to conclude that about 4 per cent. of gynecological cases have cancer.

Studdiford[10] estimates that in the greater city of New York in 1910 there were between 1,500 to 2,000 cases of carcinoma of the uterus, and between the ages of 35 to 65 there are four cases and one death from this disease to a thousand.

Howard Taylor,[11] from a study of the New York, Department of Health records, has proved that only 25 per cent. of women dying of cancer of the uterus have had a hysterectomy of any kind performed, and by correspondence with the doctors of these cases he found that in some instances it was done simply as a means of stopping hemorrhage or relieving other symptoms without any idea of attempting a cure.

Coley[12] thinks the actual death rate from cancer is far greater than statistics indicate, because among the laity there is a strong prejudice against the name cancer, therefore the family physician, out of respect for the feelings of the relatives, assigns secondary rather than primary affections as cause of death. Culliott[13] showed that in France the actual number known to have died of cancer was twice as great as reported. Riechelmann[14] has shown that in the Berlin hospitals 20 per cent. of the cases demonstrated on autopsy as cancer were not recognized during life.

Uterine cancer may be divided into two divisions, cancer of the cervix and cancer of the body of the uterus. It may occur as early as 20 and as late as 75 years of age. The greatest number of cases occur between 35 and 60. Cancer of the cervix occurs early, and cancer of the body late in life. The majority of recorded cases are found after child bearing. Especially is this true of cancer of the cervix. Falk,[15] in a careful study of all recorded cases, claims that injuries to the cervix are the most important predisposing causes. He finds that all observers show a very small proportion of nulliparæ who have cervial cancer, and true instances in virgins is of the greatest rarity. He found that the average number of births was five or six. On the other hand, Levin,[16] in a study of 613 cases of cancer of the uterus collected from metropolitan hospitals, finds that child-bearing as a whole does not seem to have the direct etiological bearing on the disease which is ascribed to it. "It is true that the number of cases of cancer in married women is a great deal higher than in single women, but so is the general ratio between married and single women during cancer age." He quotes census of 1900 to substantiate his claim, which shows that at ages 45 to 54 of deaths from all causes in women single to married, the ratio is 7:1, and from cancer it is 7.5:1.

In the treatment of cancer we have all, time and time again, had our expectations raised to the highest pitch, only to find after a time that our hopes of a cure were based on the claims of over-enthusiastic laboratory or clinical workers. To-day, as in the beginning, the cancer question remains unsolved. There is no specific, and the only means of combating this widespread disease is early diagnosis and immediate operation. It is generally conceded that cancer at some time in its early stage of development is a local condition, and that a radical removal of the growth will give a cure. But its earliest symptoms are so atypical that the laboratory workers have in the last few years developed many tests to help the clinician in a diagnosis. These tests are physical, chemical, and serological in character. "Almost every normal and abnormal body fluid, secretion, and excretion has been subjected to examination to determine, if possible, if there was not some specific reaction which would show the presence of a malignant condition." The consensus of opinion is that none of these tests are absolutely pathognomonic. The most promising are urinary tests, and among these we have the test of Salomon and Saxl,[17] who demonstrate that there is an increase of oxyproteic acid and similar substances in the urine of carcinoma patients. The test of Salomon, Saxl, and Falk,[18] who show an increase of polypeptids and the "colloidnitrogen" test of Salomon, Saxl, and Falk,[18] who show an tion of the total nitrogen content of the urine with the quantity of nitrogen precipitated by absolute alcohol or salts of the heavy metals. These tests require the most skillful technique, and are still in the experimental stage. Among the simpler tests is the methylene blue test of Fuhs and Lintz.[20] A few drops of Loeffler's methylene blue is mixed with a test tube of urine, and when shaken and allowed to stand twelve to twenty-four hours the blue color disappears. Among the serological tests is the meiostagmine reaction of Ascoli.[21] It is based on the theory that a true immunity reaction occurs in cancer as in bacterial infection. Still another is the cell reaction of Freund and Kaminer.[22] They have found that serum of normal individuals will destroy cancer cells, whereas serum of cancer patients will not. Still another, the fetal serum tests of Krauss and Graff,[23] which is based on some of the above mentioned tests, and the cell reaction of Freund-Kaminer, they conclude that the developed ovum produce in the maternal organism changes similar to those caused by a new growth. In the "antiferment" or "antitrypsin" reaction of Brieger[24] it is claimed we have a test that is of value from a diagnostic as well as from a prognostic standpoint.

These tests are as yet unreliable, and we must still depend upon subjective and objective symptoms for an early diagnosis of cancer of the uterus. The text books on gynecology are more or less obscure, as they do not sufficiently differentiate the symptoms of early and late carcinoma of the uterus. In early cancer of the uterus we do not have the classical symptoms of hemorrhage, pain, and foul leucorrhea, and we must not be misled in thinking that it is a disease only present from 45 to 60, and thus neglect a thorough examination of those cases that give us even the slightest warning earlier or later in life. The first and most frequent initial symptom of carcinoma of the uterus is bleeding, but not necessarily a hemorrhage. Kampermann found in his series of cases that in 73 per cent. the earliest manifestation of the disease was a bloody vaginal discharge. It may manifest itself most often in intercervical cancer as a prolonged or profuse menstruation followed by an ordinary profuse leucorrheal discharge, and there may be a cessation of symptoms until the next menstruation, or it may manifest itself as an occasional sudden gush of blood after unusual exertion, or by intermenstrual spotting. In cancer of the cervix the first evidence may be a slight bleeding after coitus, after the introduction of a douche nozzle, or a speculum. In these cases, by a digital examination, if it is intercervical no evidence may be obtained, or we may find the cervix is slightly hard to palpation, but it is difficult to differentiate this condition from the ordinary cystic cervix, or there may be a slight reddened area which on touch bleeds readily. In carcinoma of the body the symptoms may be nil, and only by the introduction of a sound there may be rather profuse bleeding after the ordinary cervical bleeding has ceased.

Pain in carcinoma cases is very seldom a factor until the growth has spread beyond the cervix and uterus. Although early, we may have sacral or lumbar pain irradiating down the thigh, but this pain is likewise present in many other gynecological conditions. It is not until late that we have the typical excruciating and neuralgic pain which has been found by some observers to come on toward evening and last most of the night. In 41 per cent. of Kampermann's cases a leucorrhea was the first symptom. There was no profuse hemorrhage, although later the discharge showed some color, or became blood streaked. Another point which must be emphasized is that early there is no cachexia, loss of weight or strength, and many of these cases look the picture of health. We must not be misled to prescribe in these cases a douche, give tonic, or dismiss the case as simply one of menstrual disorder. After all the only real means of making an early diagnosis is by a curettage, or by taking a section of the cervix and having the tissues thus obtained examined microscopically. I hardly agree with those who go so far as to advise every woman over 40 to go to her physician every six months for an examination, as she would to her dentist. But I do think that we as a profession are too apt to undervalue the symptoms of an irregular menstruation or the occurrence of a leucorrhea, and that we are too prone to neglect to instruct our patients in the signs of an early carcinoma of the uterus.

The nonoperative treatment of cancer of the uterus is applicable to inoperative cases, and as a means of preventing postoperative recurrence. The best results with *x*-ray, fulguration, the high frequency current and radium are in such conditions. Risely[25] has recently used in inoperable cases the ascitic fluid as suggested by Hodenpyl, and he concludes "that symptomatic relief can be obtained in a good percentage of cases, but that it has no permanent effect in preventing or in checking the growth of cancer, or in permanently benefiting the patient." Riseley[26] has also used an emulsion of cancer cells as proposed by Gilman and Coca, and concludes "that this method is not only useless but dangerous." Among other cancer emulsions, vaccines, or serums, may be mentioned the work of Vaughn,[27] and also the work of Berkley.[28] But as yet nothing seems to have been accomplished except in animal experimentation, in a few inoperable cases or as a means of preventing recurrence.

Another vaccine treatment is antimeristem of Schmidt[29], and is based on the principle of active immunization. Since the action of "antimeristem" is to produce in the body a protective force against the occurrence of carcinoma Schmidt believes its field of usefulness will be in the prevention of recurrence after operation.

Micrococcus neoformans vaccine has been used by Potter[30] in a few cases, but the principal result from this was a relief of the pain, hemorrhage, and a gain in weight, but with practically no diminution in the size of the growth.

With Wassermann's[31] eosin selenium combination based on Ehrlich's salvarsan work we have a means of treatment which has as yet been used only in animal carcinoma. "Wassermann states that, so far, they have merely demonstrated the falsity of the old theory that no substance could be found which introduced into the blood would selectively attack and destroy tumor cells without injuring the organism."

The best operative procedure for carcinoma of the uterus is still in dispute. Some operators think that a high amputation of the cervix may be all that is necessary in early cases. Theilhaber[32] calls attention to Schroder's clinic, where in the years 1878 to 1886 out of 114 partial operations 40 per cent. were alive and free from recurrence after four years, and 26.5 per cent. after eleven years. Others point to the good results obtained by the Byrne method of cauterization, and Werder[33], in a recent paper, reported 39 cases of the radical cautery operations with 46 per cent. surviving the five year period, with five subsequent deaths. Still other operators think that the best results are still to be obtained from the ordinary abdominal or vaginal total hysterectomy.

The extended abdominal operation as done by Wertheim, or the extended vaginal operation as done by Shauta, are now the operations which in the greatest number of cases give the best "absolute accomplishments." The object of both of these operations is to remove the uterus and adnexa with as much of the parametrium as possible, and also to remove a generous vaginal cuff to get well beyond the area of the growth and to prevent infection from the growth which has been proven to always harbor microorganisms, especially streptococci. In order to accomplish this there is a very complete exposure of the ureters on either side and the uterine vessels are ligated well out from the cervix.

The removal of enlarged lymphatic glands is still a question, but if time will permit it is usually done. The development of the technique has made the indications for this operation much broader

than the old vaginal or abdominal operations. Wertheim claims that every laparotomy for cancer of the uterus is exploratory until the abdomen is opened and it is found possible to do the radical operation. Jacobson[34] in 1911 reviewed 2,765 radical abdominal operations for carcinoma of the uterus, and of this number only 298 were done by American surgeons. In this series the operability ranged from 5 to 92 per cent. The European surgeons had an average operability of 65.17 per cent. and a primary mortality of 19.94 per cent., and the American surgeons an operability of only 35 per cent. and a primary mortality of 15.77 per cent. He reports the results of five European surgeons with an average of 40.72 per cent. of the operated cases alive and well five years after, and the percentage of all carcinoma cases applying for treatment alive and well from two to six and one-half years of about 21 per cent. Jacobson found it impossible to obtain any number of accurate five year statistics from American surgeons. From eleven he found that only 8.39 per cent. of the operated cases were alive and well after five years, and he estimated absolute cures at only 1 per cent.

Later American statistics (five year limit) of the extended abdominal operation for cancer of the cervix are as follows: Taussig[35] reports sixty operations by eight Western surgeons with 41.6 per cent. of operated cases alive and well with an "absolute cure" of 10.4 per cent. Cullen[36] in twenty-five cases gives a permanent cure of 24 per cent., G. H. Noble[37] in thirty-eight cases gives 34.2 per cent., Peterson[38] in six cases gives 50 per cent., Sampson[39] in eight cases gives 50 per cent., and Bovée[40] in twenty-seven cases over four years gives 30 per cent. None of these operators give per cent. of "absolute cures" or "absolute accomplishment" of the operation.

Late statistics of European surgeons show a reduction in primary mortality and a higher operability. In the extended vaginal operation for cancer of the cervix Schauta,[41] in a report of ten years' experience, gives an operability of 51.3 per cent., and in the last three years the primary mortality has been reduced to 3.7 per cent., with an absolute accomplishment of 16.6 per cent. Weibel[42] reports for Wertheim in the extended abdominal operation for cancer of the cervix an operability of 55 per cent., a primary mortality, from five hundred and first case to six hundred and seventy-fifth case of but 9 per cent., and an absolute accomplishment of 19.5 per cent. After five years there were well 43 per cent., including primary deaths, and 53 per cent., excluding these deaths.

Operability is still very low in America, and averages about 25 per cent. Quoting Ries,[43] "Operability is a condition dependent as much on the operator as much as on the patient." . . . "I know of surgeons who refuse to operate in any case of carcinoma of the cervix; others who will do only operations which have a low primary mortality; others, again, who no amount of primary mortality can deter from the most desperate attempts. Each one of them has his own conception of operability, which expressed in figures, would vary between 0 and 80 per cent. of all cases." Unquestionably the personal equation is a factor, but it will not account for the great difference in operability as shown by a comparison of American and European statistics. In America we do not see our cases as early as they do in Germany. Taylor[44] emphasizes this fact by comparing his statistics with those of Aulhorn. In his series the majority of cases were seen after the symptoms had lasted from three to six months and longer, whereas Aulhorn saw the majority of his cases with symptoms that had lasted less than three months and up to six months. It is the experience of operators in New York that few cases are seen, and then when operability is very low. Brettauer[45] in ten years, in 15,000 gynecological cases, has seen twenty inoperable and only 19 operable cases. Polak,[46] in his clinic at the Long Island College Hospital, where there are 4,000 new cases a year, had not a single operable case the last year.

I have collected a series of cases of cancer of the uterus from records of the Woman's Hospital covering all cases admitted for a period of fifteen months. I have gone over the period from December 6, 1906, to August 14, 1907, and from March 16, 1912, to November 22, 1912, and find that for these periods there were a total admission of 1,831 patients, and of this number only 46 were suffering from uterine cancer, and of this number only 23 were operable. This is especially interesting, as all were sent in to the hospital with a possible diagnosis of operability, and in only half was it possible to operate.

The present solution of the question of cancer of the uterus is to get our cases early, no matter what method of operation or cure we adopt.

In 1902 Winter[47] met this question in the following way. In East Prussia he attacked the problem along the following three lines: "(1) All practising physicians in the province were instructed, by means of a pamphlet, as to the methods and the importance of making an early diagnosis. (2) All midwives were instructed to send any carcinoma-suspicious patients to a physician. (3) By means of articles in the more important newspapers, the general public were enlightened as to the early symptoms of uterine carcinoma, and were urged to seek immediate medical advice."

Previous to Winter's campaign only 85.8 per cent. of the cases that applied to physicians for advice were given an internal examination. In the next eight years (1910) this rose to 91 per cent. The midwives previously had only referred to physicians 62 per cent. of suspicious cases, and in 1910 they referred 100 per cent. Among the laity themselves who sought advice within three months of noticing first symptoms it rose from 32 to 55.8 per cent. The increase of operability was from 62 to 69.8 per cent. The further outcome of his campaign was that in Germany nine medical organizations and eleven special societies have followed his lead, and in Austria-Hungary, France, England, Switzerland, Holland, Belgium, Russia, Denmark, Sweden, Italy, and the United States, publicity campaigns have been started. The Second International Cancer Congress held in Paris approved of the necessity of such work. Recently the Société Médicale de Rheims[48] has added to this list the druggist who often has the first opportunity of setting aright some of these early cases of uterine cancer.

When we one and all enter into the spirit and fully realize the necessity of this campaign for early diagnosis and early operation of cancer of the uterus, then and only then will any appreciable number of women be relieved of the untold suffering of inoperable uterine cancer. This will be gradually accomplished without any unnecessary dread of the disease, just as has been done by the campaign against tuberculosis.

## Medicolegal Notes.

**Consent to Operation—Measure of Damages.**—Action was brought against a surgeon for operating upon the plaintiff without her consent and performing the operation unskillfully. The defense was that the plaintiff consented to the operation, and that it was performed with proper care. The operation consisted of taking out one of the ovaries and making an adjustment of the other, and was performed at a hospital. Proof for the defendant showed that there was no neglect upon his part, and that what he did was according to the approved practice in such cases, although it turned out, in the plaintiff's case, not to relieve her. It was held that there was evidence warranting the jury in concluding that the doctor understood, and had the right to understand, from all that passed between him and the plaintiff, that he was to put her under an anesthetic, and was to perform the operation while she was under it if, upon examination, he found that necessary. There was nothing in the evidence warranting a recovery of punitive damages, as there was no evidence of bad faith, recklessness, or oppression on the part of the physician. If the defendant understood, and had reasonable grounds to understand, that the plaintiff was willing to have the operation so performed, and he performed it, he had the right to do so as by her consent. Reasonable grounds were held to be such grounds as would warrant a man of ordinary prudence to so understand under the circumstances. It was held to be error to charge the jury to find for the plaintiff such a sum as would fairly compensate her for her loss of health. Such a standard was too uncertain; for a jury might justly think that no reasonable amount of money would compensate a young woman for the loss of her health, and to give the jury such a measure of damages would be in effect to turn them loose without any criterion to guide them.—Van Meter v. Crews, Kentucky Court of Appeals, 148 S. W. 40.

**Practicing Without a License.**—In a prosecution for practicing medicine without a license evidence that the defendant had told the witness that he did not give receipts, that it was not necessary, as he could not collect by law, was held to be proper, as it would show that the defendant was aware of the prohibition of the medical practice act and that the business he was pursuing was prohibited by law. That act was held to be a reasonable exercise of the state's police powers. The legislature having defined the meaning of the words "practice of medicine" to embrace all "who shall publicly profess to be a physician or surgeon, and shall treat or offer to treat disease, etc., also all persons who shall treat or offer to treat disease, etc., for compensation," the court held that in so defining the words the legislature had rendered liable to the provisions of the act all persons who should treat disease and charge therefor, regardless of the mode or method used in so doing (including prayer and the laying on of hands) and the evidence, both for the state and the defendant, showing that the defendant was treating and offering to treat diseases and disorders, and the evidence for the state being sufficient to show that he was making charges therefor, judgment of conviction was affirmed. Proof that the defendant did not charge for his services directly, but told those who applied to him for treatment that he would receive from them "free will offerings" and that he actually did receive pay from patients, was held to be sufficient to show that he practised medicine for compensation.—Singh v. State (Texas), 145 S. W. 891.

**Compensation for Services.**—In an action for professional services for attending the defendant's minor son while sick of typhoid fever, the evidence of the plaintiff was somewhat indefinite as to the number of visits that the doctor made; but it was shown that the patient was sick about six weeks, and that the doctor visited him as often, on some days, as two or three times. It was shown that $1.50 for a day visit and $2.50 for a night visit of a doctor to a patient was a reasonable charge. In view of the common knowledge that in severe cases of typhoid fever doctors visit their patients almost daily, and sometimes several times each day and often at night, and the other facts and circumstances of the evidence, it was held that the jury's verdict of $116.30 was not excessive.—Des Mond v. Kelly (Mo., 14), 6 S. W. 90.

**Privileged Communications—Waiver of Privilege.**—The privilege conferred by the Indiana statute, providing that physicians shall not be competent witnesses as to matters communicated to them as such by patients may be waived by the patient, or those who stand in his place, or are authorized to represent him; and when a witness has been permitted without objection in a former trial to testify to privileged communications, the bar of privilege is waived, and the testimony cannot be excluded on that ground at a subsequent trial.—Studebaker v. Faylor, Indiana Appellate Court, 98 N. E. 318.

**Privileged Communications.**—The privileged communication rule under the California statute operates upon the physician alone, and confers a personal privilege on the patient, which may be expressly or impliedly waived by him in person, or by an attorney or agent acting on his behalf, such as a person to whom he has assigned a note for collection.—San Francisco Credit Clearing Co. v. MacDonald (Cal.), 122 Pac. 964.

**Privileged Communications—Waiver.**—The New York statutes prohibiting the disclosure by a physician of any information acquired in a professional capacity unless waived by the patient is absolute and it is of no consequence that the patient is not present to object to the evidence. The prohibition is effective unless the provisions are expressly waived on the trial by the patient.—Weil v. Weil, New York Appellate Division, 136 N. Y. Supp. 190.

## THE INFLUENCE OF INTRAVENOUS INJECTIONS OF MERCURY UPON ANTIBODY FORMATION.

THE treatment of puerperal fever by means of intravenous injections of corrosive sublimate was introduced about four years ago and rather extravagant claims were made in its favor. The method has probably not received a very thorough trial, and certainly theoretical considerations have been opposed to its use. One of the observers at that time, however, was impressed with the results, and has investigated the effect of such injections upon the antibody content of blood serum. Kalledey concludes from his work (*Centralbl. f. Bakt.*, Vol. lxviii, p. 358) that the intravenous administration of small amounts of mercury bichloride results in an increased antibody and complement formation in both sick and healthy animals. He studied the quantitative changes in the complement, and the normal agglutinin and lysin of pregnant women, and the specific agglutinin and lysin in rabbits immunized against sheep's red cells or the typhoid bacillus. All of these bodies reacted similarly, and it seemed to make no difference whether the dose was three or five milligrams. Following the injection there was a rather rapid fall, corresponding to a "negative phase," which reached its maximum in two days. Then began a gradual rise so that the number became normal about the fifth day and reached its height about the tenth day. The number gradually declined again until at the end of fifteen days the value of the serum was again normal.

The author is naturally reluctant to offer any explanation as to the manner in which this change is accomplished, but is inclined to believe that, as mercury is a protoplasmic poison, the negative phase represents a primary destruction of the cells. After this the cells are stimulated to increased production of protective substances. He believes that arsenic, and therefore salvarsan, acts in the same way, and that it is the quantity rather than the quality of the antibodies which determines the cure. It would be contrary to the rule for the body to react in this way to an inorganic poison, but his experiments seem conclusive and are certainly worthy of attempts at confirmation. Other recent work would tend to indicate that the quality of the antibody is of the highest importance, although no doubt the number of such bodies is not wholly a negligible factor. There are not lacking enthusiastic advocates of the use of mercury in the treatment of all infectious diseases, and this work would furnish a theoretical basis for their methods. The influence of the administration of mercury and salvarsan upon the Wassermann reaction, however, apparently constitutes a formidable objection which will have to be explained away before the theory finds general acceptance.

## THE VIRUS OF RABIES AND THE NEGRI BODIES.

A DISTINCT advance in the diagnosing of rabies followed the discovery, by Adelchi Negri in 1903, of certain cellular inclusions constantly present in the nervous system of animals affected with this disease. In the past ten years many of our health boards have used means for the recognition of these bodies which have come to be regarded of prime importance in the diagnosis of rabies. Negri himself worked for nearly ten years in studying these bodies and successively demonstrated their presence in various animals suffering from rabies. His work has been confirmed by many observers the world over. The findings have been so generally uniform that it has come to be recognized that when Negri bodies are found in the ganglion cells of the hippocampus major it is a positive sign of rabies. These bodies have been further studied by researchers with a view to proving their parasitic nature but without advancing our knowledge of them any more than in the case of the Guarnieri bodies caused by vaccine virus. The smallest of these bodies are almost ultramicroscopic and react to stains like nuclear particles, but the largest—the typical Negri bodies—are readily differentiated from nuclear particles by appropriate staining methods. Any further light upon the significance of these bodies is to be welcomed, especially since, every now and then, some false prophet preaches that there is no such disease as rabies. Pasteur's work alone in 1884 should refute this.

Recently Acton and Harvey of the Pasteur Institute in India have published a report of their studies on the fixation of rabies virus in the monkey (*Macacus rhesus*) with a study of the appearance of Negri bodies in the different passages (*Parasitology*, Vol. 5, No. 4, February, 1913). These authors found that the street virus of the dog becomes exalted and fixed by successive passage through the monkey, just as in the rabbit and other animals; the type of rabies being at first furious, but after the seventh passage, paralytic. With each successive passage the Negri bodies were found to be smaller in size until ultramicroscopic. After the seventh passage, when the paralytic form of rabies was fully developed, very few Negri bodies were found. This diminution of the number of Negri bodies seems to bear a definite relation to the fixity of the virus as shown by another experiment. The authors inoculated two bullocks, one with street virus and the other with fixed virus. The street virus caused large Negri bodies, whereas the fixed virus caused none at all—and this in an animal showing the largest Negri body known.

The results of these experiments are of especial value because of the use of the monkey, and they are illuminating in the study of other cellular inclusions which, like the Negri body, have been regarded as protozoan parasites.

### Alimentary Toxemia in Its Relation to the Teeth and Mouth.

Alimentary toxemia is nowadays a very widely discussed subject. Of course, it has been recognized for long that if the digestive organs do not act normally the entire system will soon be thrown out of gear. Recently, however, efforts have been concentrated upon discovering the essential causes of indigestion, so as to be able to strike at the root of the evil, rather than, as is too often the case, merely to treat the symptoms. As one result of these more thorough and painstaking investigations carious teeth and oral sepsis generally have been stigmatized as some of the chief factors in the causation of alimentary toxemia. In a discussion on this matter which took place before the Royal Society of Medicine on April 14, Mr. J. G. Turner stated that from observation of the results of treatment directed to dental sepsis only, he was sure of the existence of an alimentary toxemia due to this condition. The components of dental sepsis and dental caries, pyorrhea, tartar, artificial causes of sepsis, were all governed by the root-factor stagnation, stagnation of germs and soft, starchy, and sugary foods. It might be termed germ-carbohydrate stagnation. He gave the results of his observations, showing that both in man and in the lower animals dental sepsis ran parallel with the occurrence of germ-carbohydrate stagnation, citing the occurrence of pyorrhea and dental caries in South Sea Islanders and in captive monkeys. The islanders made extensive use of cocoanuts and captive monkeys were largely fed on bread. Jaws of the seventeenth and eighteenth centuries showed far less pyorrhea than those of today. Fine ground flour was the determining factor. In treatment the most radical was the safest means, in hospital practice especially so, because of the danger of artifact sepsis. Those who had not inquired would be astonished to find how many persons lived comfortably with few or no teeth. He did not wish to be understood to say treatment short of extraction was useless. Most gratifying results could be obtained by local treatment if the patient could maintain the clean state so arrived at. For prevention Turner urged cleanliness and a return to bread made of coarse ground meal.

### Well Fitting Shoes for the Army.

Shoes which fit comfortably are necessary to the well being of every individual, and especially does this remark apply to the soldier. If a shoe does not fit well it brings about not only extreme discomfort, but not infrequently injury and even malformation. The fact is now recognized by the army authorities, who, according to the report of the Surgeon General for 1912, have become fully convinced of the necessity for having military shoes made on a correct last and properly fitted. However, although the conviction reigns, the marching shoe with which the rank and file of the army are supplied does not meet with the approval of various surgeons. The majority of them report (1) that the toe of the shoe is too low; (2) that the toe of the shoe does not properly protect the toes of the foot; (3) that the width of the shoe is too great for the length, hence if a shoe is long enough for the foot it is too wide; (4) the instep is too low. The question has been under consideration for several months by a board at Fort Leavenworth, with Major E. L. Munson of the Medical Corps as president. A great many radiographs have been made of feet with shoes of various patterns and without shoes. These radiographs show that practically the feet of all adults are deformed from wearing shoes made on improper lasts. The board suggested that a number of shoes be made on a set of lasts recommended by them, and that a practical test be made of these shoes under the supervision of the board. This was done and a command of 379 men was properly fitted with these shoes under the supervision of the board and went out on a practice march of 117 miles, occupying nine days. Careful notes were kept and examinations made, both by inspection and by the *x*-ray. The results were so satisfactory that the conclusion has been reached that a satisfactory field shoe has been devised as the result of the work of the board.

### The Nutritive Effects of Pasteurized Milk.

Although pasteurized milk is now very largely used, there is yet considerable divergence of opinion with regard to the effects produced on the nutritive value of milk by this process. There are some, in fact, who still hold that milk is injured as a food by the method. It is therefore encouraging to note that in response to a letter dated April 4, 1912, received from a committee representing the Washington Section, Woman's Welfare Department of the National Civic Federation, and the Association for the Prevention of Tuberculosis in the District of Columbia, asking that a study be made by the Public Health Service in cooperation with the Bureau of Animal Industry of the Department of Agriculture as to the effects of pasteurization on the nutritive value of milk and also of the relative value of raw and pasteurized milk as food for infants and invalids, the service and association in question have consented to cooperate in this investigation. A feeding station with the necessary equipment has been established at the Hygienic Laboratory for these studies, Passed Assistant Surgeon A. M. Stimson being placed in charge of them. It is planned to continue this investigation for at least one year, and preferably longer, in order to make the results of real value.

## News of the Week.

**Report on the Friedmann Culture.**—At the meeting of the National Association for the Study and Prevention of Tuberculosis in Washington on May 9, Dr. John F. Anderson of the U. S. Public Health Service, chairman of the Government board which has been investigating the claims of Dr. Friedmann, presented a short report. The report read, in part, as follows: "Without presenting in detail the condition of patients under observation, we are in a position to state that the effects, thus far observed, do not justify the confidence in the remedy which has been inspired by widespread publicity. In our opinion harm may have been done by this undue publicity, in so far as it has lessened the confidence of tuberculous persons in well recognized methods of treatment or interrupted their

use, and we are constrained to advise against any lessening of those well-known measures, which not only have effected cures, but which have reduced the incidence of the disease." Following the reading of the report the Association adopted these resolutions: "Whereas, Widespread publicity has been given to the claims of an alleged cure for tuberculosis. Resolved, That there is no information before the National Association for the Study and Prevention of Tuberculosis to justify the belief that any specific cure for tuberculosis has been discovered which deserves the confidence of the medical profession or the people, And, Resolved, that it is the duty of the public to continue unabated all the present well-tried agencies for the treatment and prevention of tuberculosis."

**City Death Rate.**—During the week ending May 6 there occurred in New York City 1,532 deaths, giving a death rate per thousand of 14.88, as compared to 1,542 deaths and a rate of 15.55 during the corresponding week of 1912. The deaths during the week from measles, scarlet fever, bronchopneumonia, and pulmonary tuberculosis were considerably decreased, while increases occurred in those due to organic heart disease and lobar pneumonia.

**Osteopaths May Sign Death Certificates.**—At a meeting of the Board of Health of New York City on May 7 an amendment to section 163a of the Sanitary Code was adopted, thus giving to certificates of death signed by osteopaths who have been licensed after passing the New York State examination the same force as regards the issue of burial permits as those signed by physicians holding the degree of M.D.

**Memorial to Dr. Bristow.**—The Bushwick Hospital, Brooklyn, N. Y., has received a gift of $1,500 for the equipment of an *x*-ray room in that institution as a memorial to the late Dr. Algernon T. Bristow.

**Tuberculosis Statistics.**—The New York Department of Health has recently compiled statistics which show that the number of new cases of pulmonary tuberculosis in this city has steadily declined each year since 1910. In that year 32,065 cases were registered, while in 1912 there were 22,752 cases. In Manhattan and the Bronx the mortality figures have fallen consistently from 4.27 per thousand in 1881 to 1.9 per thousand in 1912. Since 1908 the death rate from consumption in the entire city has dropped from 2.25 to 1.66 per thousand.

**Mortality in the State.**—During the month of March, 1913, the mortality in New York State was unusually large, the total number of deaths being 14,089. Pneumonia caused 1,456 deaths; pulmonary tuberculosis, 1,395, and cancer, 761. During the same month there were 19,582 births.

**Tonsillitis Epidemic.**—An epidemic of tonsillitis in Canton, Mass., during the last few weeks has caused the deaths of several persons, and of the entire population of 3,000 at least 400 are reported to be ill with the disease. The source of the epidemic has not been determined.

**Radium Work at Harvard.**—A study of the effects of radium in the treatment of cancer is shortly to be begun at the Harvard Medical School under the direction of Dr. William Duane, a former worker in Mme. Curie's laboratory. The work will be supervised by the Cancer Commission of Harvard University, of which Dr. E. E. Tyzzer is director, and for the present will be carried on in the Collis P. Huntington building, though it is hoped that later a separate building will be constructed near the Medical School and devoted entirely to the radium work.

**Tufts Medical School.**—The trustees of Tufts College, Boston, have appointed as Dean of the Medical and Dental Schools Dr. Charles Fairbank Painter, at present professor of orthopedic surgery in the institution. Dr. Painter succeeds Dr. Harold Williams, who recently resigned the deanship and has been made professor emeritus of the practice of medicine. Dr. Elwood T. Easton has been appointed professor of ophthalmology, succeeding Dr. Henry B. Chandler, resigned.

**Civil Service Examinations.**—The United States Civil Service Commission announces an examination on June 4, 1913, open to men only, for physicians to fill vacancies in the Isthmian Canal Commission at entrance salaries of $1,800 per annum, one vacancy being in the Insane Asylum at Ancon, Canal Zone, for which an unmarried man who has had experience in the treatment of the insane is desired. It is desired also to fill a vacancy in the position of acting assistant surgeon in the Public Health Service at Jacksonville, Fla., at a salary of $500 per annum. Appointees to such positions are required to devote only a part of their time to the Government service.

On the same date, examinations, open to men only, will be held for the purpose of filling vacancies in the position of dentist in the Indian Service at Large, at a salary of $1,500 per annum, and in the position of dental interne in the Government Hospital for the Insane, Washington, D. C., at a salary of $600 per annum. Details as to all these examinations may be secured on application to the United States Civil Service Commission, Washington, D. C.

**Army Medical Corps.**—The Surgeon General of the Army announces that preliminary examinations for appointment of first lieutenants in the Army Medical Corps will be held on July 14, 1913. The essential requirements are that the applicant shall be between twenty-two and thirty years of age, a graduate of a reputable medical school, and of good moral character and habits, and shall have had at least one year's hospital training as an interne after graduation. Full information can be procured upon application to the Surgeon General, United States Army, Washington, D. C. There are at present forty vacancies in the Medical Corps of the Army.

**Gifts to Charities.**—The Good Samaritan Dispensary, New York, receives a bequest of $10,000 under the will of the late Samuel Riker of this city.

By the will of the late Miss Alicia M. Curtis of Hanover the sum of $50,000 is left to the New England Hospital for Women.

A bequest of $5,000 to the Babies' Hospital, New York, is included in the will of the late Mrs. Robert W. Todd.

Five thousand dollars goes to the Englewood Hospital of Englewood, N. J., by the will of Mr. Joseph Lyman who died recently at Wallingford, Conn.

By the will of the late William Kaufmann of Philadelphia the sum of $5,000 is bequeathed to the Jewish Hospital for the endowment of a free bed.

**Smallpox in Philadelphia.**—The discovery on May 10 of five cases of smallpox in colored persons in the northern section of Philadelphia led to the temporary quarantine of 300 houses and the vaccination of nearly a thousand persons.

**Death from Anthrax.**—A worker in a curled-hair factory in Philadelphia died on May 9 from anthrax shortly after handling a bale of hair from Siberia.

**Phipps Institute for Tuberculosis.**—The new building of the Henry Phipps Institute of the University of Pennsylvania for the Study, Prevention, and Treatment of Tuberculosis was formally dedicated at Philadelphia on May 10 in the presence of a notable body of physicians and sociologists. At the same time the honorary degree of doctor of laws was conferred on Mr. Phipps and on Dr. Edward L. Trudeau. The opening address was made by Dr. Edward F. Smith, provost of the university, who conferred the degrees, and he was followed by Dr. Lawrence F. Flick, who gave an historical sketch of the Institute prior to its affiliation with the university, and by Dr. Herman M. Biggs of New York City, who reviewed the tuberculosis situation and offered suggestions as to the future activities and influence of the institute.

**Section on Laryngology of the Academy of Medicine.**—Dr. Chevalier Jackson of Pittsburgh will read a paper before the Laryngological Section of the New York Academy of Medicine on Wednesday evening, May 28, at eight-thirty o'clock. The subject of the paper will be: "A Lantern Demonstration of Laryngostomy and of Plastic Operations for the Formation of Adventitious Bands." The profession is cordially invited to attend.

**Memorial to Dr. Morrow.**—A meeting to commemorate the life and work of the late Dr. Prince A. Morrow will be held by the Society of Sanitary and Moral Prophylaxis on Thursday evening, May 22, at the Academy of Medicine, 17 West 43rd Street. The program will be as follows: "Dr. Morrow, the Physician," by Dr. Edward B. Bronson; "Dr. Morrow, the Educator," by Dr. Edward L. Keyes; "Dr. Morrow, the Philanthropist," by William A. Purrington, Esq.; "Dr. Morrow's Work in Uplift," by the Rev. John P. Peters, D.D.; "The Pioneer Qualities of Dr. Morrow as a Social Reformer," by Dr. Charles W. Eliot.

**American Academy of Medicine.**—The thirty-eighth annual meeting of the American Academy of Medicine will be held at the Leamington Hotel, Minneapolis, Minn., on June 13, 14, and 15, 1913, under the presidency of Dr. Ray Lyman Wilbur of San Francisco. A copy of the preliminary program may be obtained from the secretary, Dr. Charles McIntire of Easton, Pa.

**Northern Medical Association.**—The annual reunion and dinner of this society was held in Philadelphia on the evening of April 30, Dr. James Tyson, professor emeritus of medicine in the University of Pennsylvania, being the guest of honor. Dr. Henry Beates, Jr., presided at the dinner, and addresses were made by Dr. John B. Deaver, Dr. William E. Robertson, and others.

**Travel Study Tour.**—The travel study tour of American physicians to include the XVIIth International Congress of Medicine in London will start from New York on July 3, passage being taken on the *Bremen* of the North German Lloyd line. About seventy-five physicians will be in the party. In cooperation with the International Committee for Post-Graduate Medical Education, arrangements have been made for visits to clinics and hospitals in Paris, Munich, Vienna, Berlin, Dresden, Cologne, and Brussels, and the party will finally reach London in time for the congress. Dr. Richard Kovács of 236 East 69th Street, New York, is the secretary of the study tour.

**The American Dermatological Association.**—At the thirty-seventh annual meeting of the American Dermatological Association, held at Washington, D. C., May 6, 7 and 8, 1913, the following officers were elected for the ensuing year: *President,* James MacFarlane Winfield of Brooklyn; *Vice-President,* S. Pollitzer of New York; *Secretary and Treasurer,* Oliver S. Ormsby of Chicago; *Member of Council,* William A. Pusey of Chicago. Chicago was selected as the next place of meeting.

**The Northeast Oklahoma Medical Society** was organized at a meeting held in Tulsa recently, the following officers being elected: *President,* Dr. G. H. Butler, Tulsa; *Vice-Presidents,* Dr. B. W. Freer, Nowata; Dr. G. F. Woodring, Bartlesville; Dr. John B. Donahoe, Afton, and Dr. Louis Bagby, Vinita; *Secretary,* Dr. John V. Athey, Bartlesville; *Treasurer,* Dr. W. A. Howard, Chelsea.

**Berkshire District (Mass.) Medical Society.**—At the annual meeting held in Pittsfield on May 1 the following officers were elected: *President,* Dr. John B. Thomes, Pittsfield; *Vice-President,* Dr. F. C. Downing, Lanesboro; *Secretary,* Dr. O. L. Bartlett, Pittsfield; *Treasurer,* Dr. J. D. Howe, Pittsfield.

**Medical Club in Philadelphia.**—The Presiding Judges of the Courts of Philadelphia were the guests of honor at a reception given recently by the Philadelphia Medical Club. Addresses were made by the Judges, and memoirs of the late Dr. Roland G. Curtin and the late Dr. George B. McClellan, former presidents of the club, were read.

**Museum of Safety.**—An International Exposition of Safety and Sanitation will be held in New York, in December, 1913, under the auspices of the Museum of Safety.

**Obituary Notes.**—Dr. John Haven Emerson of New York, a graduate of the College of Physicians and Surgeons, New York, in 1864, and a member of the Physicians' Mutual Aid Society, and the Clinical Society, died at his home suddenly from apoplexy on May 4, aged 73 years.

Dr. Robert D. Robinson of El Paso, Texas, a graduate of the Kentucky School of Medicine, Louisville, in 1887, and a member of the Texas State and El Paso County Medical Societies, died suddenly at his home on April 9, aged 52 years.

Dr. Joseph B. Fenwick of Chelsea, Mass., a graduate of the Harvard Medical School in 1872, a member of the Massachusetts State and Suffolk County Medical Societies, and an associate on the staff of the Chelsea Hospital, died at his home on April 26, aged 75 years.

Dr. Margaret V. Doane Kimball of Healdsburg, Cal., a graduate of the University of Michigan, Department of Medicine and Surgery, in 1880, died at her home after a short illness on April 17, aged 60 years.

Dr. Mary Bridges Beattie Cornish of Everett, Mass., a graduate of the University of Toronto, Faculty of Medicine, in 1906, formerly pathologist at St. Luke's Hospital, New Bedford, died at her home, shortly after giving birth to a child, on April 23, aged 30 years.

Dr. Edgar Garceau of Boston, Mass., a graduate of the Harvard Medical School in 1890, a member of the American Medical Association, the Massachusetts State and Suffolk County Medical Societies, the American Gynecological Society, the Obstetrical Society of Boston, the American Urological Association, the New England Branch of the American Urological Society, and the Boston Medical Library Association, and consulting gynecologist to the

Quincy City Hospital, and gynecologist to the Boston Dispensary and St. Elizabeth's Hospital, died at his home after a brief illness on April 29, aged 46 years.

Dr. Charles W. Price of Richmond, Me., a graduate of the Medical School of Maine, Portland, in 1875, a veteran of the Civil War, and a member of the Sagadahoc Medical Club, died at his home on April 25, aged 69 years.

Dr. Edward M. Small of Eastport, Me., a graduate of the Jefferson Medical College, Philadelphia, in 1871, died at his home on April 27, aged 66 years.

Dr. J. H. Grady of Columbia, Ky., a graduate of the University of Louisville, Medical Department, in 1868, died at the home of his daughter in Quincy, Ill., on April 22, aged 70 years.

Dr. Archibald B. Sellards of Lawrence, Kan., a graduate of the Miami Medical College, Cincinnati, in 1875, a veteran of the Civil War, died at his home suddenly from paralysis on April 20, aged 68 years.

Dr. Thomas W. Mulhern of Greenfield, Ia., a graduate of the College of Physicians and Surgeons, Keokuk, in 1882, and a member of the Iowa State and Adair County Medical Societies, died suddenly on April 21, aged 68 years.

Dr. Thomas J. Lymington of Ackley, Ia., a graduate of Queen's University, Medical Faculty, Kingston, Ont., in 1881, and a member of the American Medical Association and the Iowa State and Hardin County Medical Societies, died at his home from blood poisoning on April 21, aged 56 years.

Dr. Alvah F. Whitman of St. Paul, Minn., a graduate of the University of Michigan, Department of Medicine and Surgery, in 1865, died at his home after a short illness, on April 20, aged 81 years.

Dr. Hermann Kahn of New York, a graduate of the University of Wurzburg, Germany, in 1861, died at his home on May 1, aged 79 years.

## Obituary.

### LOUIS A. DUHRING, M.D.,

PHILADELPHIA.

Dr. Louis A. Duhring died in Philadelphia on May 8 at the age of 67 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1867, subsequently serving for 15 months as interne in the Philadelphia Hospital. Later he went abroad, spending two years in study in Paris, London and Vienna. On returning to Philadelphia in 1870 he established a dispensary for the study and treatment of diseases of the skin, serving as attending physician for a period of seven years, and later becoming consulting physician. In 1871 he was made clinical lecturer on diseases of the skin in the University of Pennsylvania, and in 1876 he was advanced to the professorship of that branch, serving until 1911, when he was made emeritus professor. He was a Fellow of the College of Physicians of Philadelphia, a member and one of the founders of the American Dermatological Association, honorary member of the London, Vienna, and Italian Dermatological Societies, corresponding member of the New York, French, and German Dermatological Societies. He was the author of several formal publications dealing with diseases of the skin and a liberal contributor to the literature of the subject.

## Correspondence.

### A SHORT-CIRCUIT WARNING.

To the Editor of the Medical Record:

Sir:—Lest that weight of authority, which is an integral part of almost everything that our eminent colleague, Robert T. Morris, writes, may lead some to error, I desire to call attention to a paragraph in his article on "Peritoneal Adhesions of the Insidious Toxic Group," printed in the Medical Record of April 12. "This operation consists in a simple short-circuiting of the colon. The ileum or cecum is placed against some convenient segment of the sigmoid colon, and the two structures, held temporarily by traction sutures, are quickly united in such a way that 4 or 5 feet of the offending colon are thrown out of commission. Sufficient storage room is left for fecal matter, but the large useless area of the colon is no longer able to turn into the circulation a harmful flood of toxins. The short-circuiting operation can be done through a comparatively small incision, and with so little attendant shock that we sometimes see a patient reading a newspaper next morning in bed and sitting out of bed in ten days."

This is so very simple, that, coming as it does, there will be some venturesome ones who will try it with a strong probability of having fecal regurgitation and accumulation in the excluded colon. Lane's short-circuit operation for intestinal stasis is certainly one of the most valuable contributions to surgery that has been made in this generation. But Lane's technique must be followed without any variation if we may expect uniformly good results. In our town a few weeks ago a surgeon removed a distended colon containing 17 pounds of feces. It had been short-circuited at a very celebrated clinic, possibly in some such way as the paragraph of Dr. Morris might be taken to mean by those not properly informed.

An esteemed internal medicine colleague protested loudly against Lane's short-circuit operation at a meeting of a medical society when I mentioned in discussion having done forty of these operations. He had recently returned from a prolonged sojourn in Vienna. There he had seen the enormously distended colon removed in two cases where short-circuit operations had been done. Later, on questioning him, I found that the cecum had been anastomosed with the sigmoid, which one might infer, from reading the paragraph of Dr. Morris, was a proper thing to do. It is certainly easy, and the patient may "read the paper the next morning." If one were more venturesome it might even be done in the office under local anesthesia, and the patient return home in the street car.

Lane's short-circuit operation is not an anastomosis of the ileum with "some convenient segment of the sigmoid colon." It is an end-to-side anastomosis of the severed ileum with the upper part of the rectum. To harmonize the nosology of the embryologists, let me explain that the anastomosis must be made in the straight part of the lower bowel at the lowest possible point at which it can be made with reasonable tension. Anastomosis above this point may leave a distal fold of the sigmoid, possibly one of the original causes of the stasis, where it will favor regurgitation.

There is also one necessary step in the operation which cannot be safely done through a very short incision. The severed ileum has been trans-

ferred to a new attachment from the right to the left side. This leaves an opening in the mesentery through which the intestine might readily pass and cause obstruction. This must always be closed by a suture passed bit by bit under the peritoneum of the mesentery between the severed portion of the ileum and the anastomosis in the lower bowel. The mesentery here contains many large vessels, the wounding of which by a needle puncture might be serious. Each portion of the peritoneum must be picked up by forceps before the needle is passed through it. This suture is first placed like a purse-string and secured by forceps, and later carefully tied after the anastomosis is made, making sure that no loop of intestines has slipped within its grasp. Finally the operation is completed by having an assistant pass a rectal tube, which the operator guides through the anastomotic opening upward for about a foot into the ileum. This is a most valuable aid in preventing postoperative distention. All this cannot be safely and well done through what is ordinarily considered by Dr. Morris to be a short incision, and yet every part of this technique is necessary for uniformly good results. The incision should extend from the pubes to the umbilicus.

Done as I have indicated, the results are satisfactory, and the patient may indeed commonly "read the paper in bed the next morning."

A. E. Rockey, M.D.

Alder St. and Broadway, Portland, Ore.

## OUR LONDON LETTER.

(From Our Regular Correspondent.)

ANTIVIVISECTIONISTS' LIBEL ACTION — HOSPITAL FUNDS—ALIMENTARY TOXEMIA DISCUSSION—BEHRING'S SERUM—EPIDEMICS—ELECTRICAL AMBULANCES—RED CROSS—OBITUARY.

London, April 25, 1913.

The antivivisectionists have lost their action. On the sixteenth day of the hearing the jury gave their verdict for the defendants, and judgment was entered for them with costs. These must amount to many thousands of pounds, but may be regarded as advertisement expenses. No doubt it must be a costly method, but it has practically kept "the cause" of these antis before the public for more than a fortnight. The plaintiff, Miss Lind af Hageby, as I reported to you, acted as her own counsel, and proved herself equal to the post. She was able to state her views at great length, and to interpolate many biographical incidents and to interest the readers of the daily papers. As witnesses she put in the witness box a number of her followers, including half a dozen qualified medical men. The defence contented themselves with the same number of medical witnesses, but all of them could speak with knowledge, and all are well known as scientific authorities. The judge summed up on the sixteenth day and told the jury what were the facts at stake. He complimented the plaintiff on the conduct of her case; on her power to stand day after day without showing fatigue, and ability to speak and cross examine as well as a member of the bar. But it was her duty to fight fairly and truthfully. She might express her opinions most strongly, but was not entitled to make untrue assertions. He referred to her statement that six and one-half millions of people had died in India from the effect of serum treatment. She had declared she adhered to the terms of an open letter to Lord Cromer; if so Lord Cromer might well bring an action against her. He was somewhat puzzled at the antivivisectionist's argument that one may cut up a mouse to save the mouse's life, but not to save human life. Did the jury think the defendants had made out their plea of justification and proved substantially the truth of their allegations that the plaintiff had been guilty of mendacity and carried on the campaign untruthfully they would be entitled to say her case was not proved. And that was not all. There was the plea of fair comment. Would they carry on a campaign as this had been carried on? Miss Lind, in her reply, had appealed very strongly, but verdicts are not given on oratory, but on evidence, and they must do their duty. After about twenty minutes' absence the jury returned to court with a verdict for defendants.

The annual meeting of King Edward's Hospital Fund was held on Wednesday. The report was moved by the speaker and carried unanimously. It stated the total receipts for 1912 were £179,378, the amount distributed, £157,500, of which the hospitals received £151,000, the remainder being distributed among sanatoria and convalscent homes taking London patients. During the last ten years over £1,300,000 has been thus distributed by this fund, and since its foundation over £1,633,000. The council emphasized the fact that the income from investments represents only about half the amount of the annual awards, and to maintain the present rate of distribution the fund is dependent on the contributions of the year. Every institution applying for a grant was inspected and reported upon by visitors of the fund, one medical and one layman in each case. The number of beds secured in sanatoria placed at the disposal of the hospitals is now thirty-nine in five different institutions. The annual statistical report on the expenditure of London hospitals deal with 107, giving an analysis of the expenses of all those which have adopted the revised uniform system of accounts. Since these reports were first issued, in 1903, there has been a regular reduction of cost, amounting at length to above £37,000 a year, and that in spite of a rise in prices of many necessaries and the constant introduction of new methods of treatment.

The Hospital Saturday Fund's annual meeting was held on the 19th. A shrinkage of income has followed the insurance act, but the work has not diminished; it has really increased, for 2,000 more benefits were granted than in the previous year. The chairman said the needs of the great hospitals were no less, and the secretary of the London hospital had stated that not a single person had been turned away from that great hospital during the last two or three months. The report was unanimously adopted, and afterawrd Dr. T. D. Lister read a paper on tuberculosis, and moved a resolution approving of the system of forming dispensaries in the various metropolitan boroughs to promote prevention of consumption and spread knowledge about it. This was also carried.

The discussion on alimentary toxemia was resumed at a special meeting of the Royal Society of Medicine on the 14th inst. Mr. Lawford referred to the reported connection with diseases of the eye as widely recognized, although many were still disposed to dispute it. No one doubts that toxemia is often associated with oral sepsis, especially from chronic gingivitis and pyorrhea alveolaris. So chronic iridocyclitis has been attributed to the same cause, since Mr. Lang pointed it out. Choroiditis

mostly of the exudative type was also likely to occur in the course of oral sepsis and other infections; so were the several forms of scleritis. It was thought that tonsilitis might elaborate a toxin which would set up ocular lesions, and the same was asserted of intestinal derangements. These last were perhaps the most potent of all, for diseases in which such toxins abound in the intestines, *e.g.* dysentery, are often accompanied by retinal hemorrhage, or phlebitis and choroiditis. Retroocular neuritis might be due to autotoxemia, and ophthalmic surgeons may well remember this in reference to the infections which occur after operations.

Professor Dixon said the toxins produced in the alimentary canals were derived from amino acids. These were not themselves poisonous, but became so when acted on by certain microorganisms which removed a molecule of $CO_2$. Small quantities of the amino acids were always present in the canal, and the microorganisms probably had a beneficial effect in health.

Dr. Ledingham discussed the bacteriological and biochemical evidence put forward by the Metchnikoff school, in which he put but little confidence so far, though he thinks further researches in this direction may lead to more certain results.

Dr. Galloway spoke of cutaneous affections in relation to the toxins. He divided such manifestations into four groups: (1) Those which may result from disturbances of the blood vessels, and disappear, leaving no permanent trace; (2) inflammatory lesions, progressing to infiltration of the integuments with cellular elements, and terminating in persisting deformity, such as dilatation of blood vessels, atrophy, ulceration, and scarring; (3) purpura punctate or diffuse—often with other hemorrhagic manifestations; (4)pigmentation due to increase or abnormal distribution of pigments closely related to those of the normal type, such as melanin, or in other cases to pigments more recently derived from hemoglobin, and due to hemolysis resulting from the circulating intestinal toxins.

Dr. Mantle said numerous invalids visited Harrogate with symptoms which he thought traceable to absorption of toxins from some part of the alimentary tract, and it was well to endeavor to localize the spot, which might be anywhere in the length of the canal. Perhaps the commonest was in the colon, due to constipation and stasis of the contents. But absorption did not usually occur unless abrasions or a very weak mucosa increased the favorable conditions. Sometimes there was a more general infection of mucous membranes, including the respiratory. Treatment should be directed to removing all toxins from the canal throughout its whole length. He had found intestinal lavation with sulphur water useful, also warm sulphur baths to assist arthritic or cutaneous manifestations.

Mr. J. G. Turner was certain from treatment alone that there exists a dental sepsis arising from stagnation of germs and the debris of soft, sugary, starchy foods. It might be called "germ-carbohydrate" stagnation. Cats and dogs were similarly affected, as they were fed a good deal on pappy food. Monkeys in the zoological gardens often died from enteritis, but long before this pultaceous matter could be squeezed from the gums.

Dr. A. F. Hertz, in a careful contribution to the discussion, remarked that the symptoms commonly regarded as characteristic of intestinal stasis were by no means pathognomonic, and he showed the value of the bismuth meal and of the *x*-rays for determining the spot at fault. With proper precautions in diagnosis it would be found that intestinal did not lead to gastric stasis, nor to duodenal kinking, dilatation, or ulceration, but ulcers of the duodenum are associated with rapid passage of chyme from the stomach and all through the small intestines. In the ileum there is a normal stasis produced by the ileocaecal sphincter. Kinks here are rare, and do not increase the normal stasis, but it may be increased by spasm, or failure of the sphincter to relax as a result of disease in the neighborhood of the caecum, perhaps including iliac kinks.

Normally the hepatic and splenic flexures appear under *x*-rays to be acutely kinked, but this is only because the shadow is thrown at an angle with the colon. Ptosis of intestine does not cause stasis except in rare instances at the splenic fixture—a pelvic caecum and a pelvic colon being compatible with perfect health and normal intestinal action. In most cases of constipation only one part is at fault, and to that treatment should be directed. Medical treatment almost always succeeds when the colon is involved in its whole length, so that the necessity for surgery is exceedingly rare. In only one case Dr. Hertz advised resorting to an operation.

Mr. Coleman gave an account of toxemia arising from lesions and conditions of the mouth, teeth, and gums.

Dr. G. Monod of Vichy, who was a visitor, supported Dr. Mantle as to the value of spa treatment.

At the Wiesbaden Medical Congress, which closed on April 18, Prof. Behring announced a modification in his diphtheria serum, which overcomes the defect of the too short duration of its prophylactic influence. He now combines an antidote with the serum, and several speakers testified that real protection was obtained by them from its use. One said he had transferred the serum to another child with success, and claimed it as the first time that passive immunity had been produced with human diphtheria serum. Another said he had injected the serum into the vertebral canal, and thereby restored a patient who was in an extremely critical state. A Hamburg physician remarked that in the late epidemic there the mortality kept high, notwithstanding the use of serum. A Berlin physician said in that city statistics showed that since serum came into use, though mortality fluctuated, the proportion of deaths to cases had fallen half. Perhaps in more severe epidemics it might not be so great.

Dr. J. T. C. Nash, in his Chadwick lecture, on Monday, applied to the evolution of epidemics that of species in adapting their conditions to those of their environment. He thought that the history of the prevalence of phthisis permanently in a community shows, much as is the case with infective diseases as a whole, that after being endemic for a considerable period, it tends to lose some of its violence and so assume a milder type.

Some electric ambulances have been in use here for a time, and their value was illustrated a day or two ago by two accidents. In one the electric ambulance was available, and in reply to telephone, arrived on the spot with assistance and all appliances in a few minutes. In the other, it was longer before help could be had, and though about the same distance from the hospital, that distance had to be traversed very slowly. The facts were stated at an inquest when the jury expressed the opinion that electric ambulances should be provided all through

London, and requested their views to be transmitted to the authorities.

Col. Bedford, R.A.M.C., on Saturday inspected a branch of the Red Cross. Detachments were mobilized and emergency hospitals organized, with an isolation ward in one. Boy scouts were utilized as patients, brought into hospital by their comrades on stretchers, the equipment, nursing, and everything being exactly as under war service conditions. The inspector expressed approval of all the arrangements.

Mr. R. B. Etherington-Smith died on the 19th of April in St. Bartholomew's Hospital, to which he was an assistant surgeon and the warden of the college. He was seized with peritonitis on the 16th, and the next afternoon submitted to an operation. He was only 36 years of age. He took M.A., M.B., and C.M., Cambridge, in 1907. He had qualified in 1903, and in the following two years held the posts of house surgeon and ophthalmic house surgeon for the usual periods at St. Bartholomew's, where he had filled his medical curriculum. Subsequently he was demonstrator of anatomy, and of morbid surgical anatomy, and registrar. Afterwards he was appointed warden, and on the surgical staff. He was one of the most promising young surgeons, and a great career seemed to be before him. He was also a distinguished athlete and a great favorite with students, both at St. Bartholomew's and Cambridge.

## OUR CANADIAN LETTER.

(From Our Regular Correspondent.)

THE THIRTEENTH ANNUAL MEETING OF THE CANADIAN ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS—COCAINE IN CANADA—THE MEETING OF THE CANADIAN MEDICAL ASSOCIATION.

MONTREAL, April 4, 1913.

THE annual meeting of the Canadian Association for the Prevention of Tuberculosis was held in Ottawa, in March. The meeting was held considerably earlier in the year than is usually the case in order to allow of the presence of H. R. H. the Duke of Connaught before leaving for England. So far as attendance was concerned the meeting was the largest on record; so large was it, indeed, that for the opening meeting the Russell Theater had to be engaged. The abnormal attendance was not wholly due to the presence of the Duke but probably was owing more to the fact that Dr. Friedmann had consented to address the meeting upon the principles underlying his treatment of tuberculosis. The Russell Theater was crowded to its utmost capacity, a goodly proportion of the audience being ladies. After Sir James Grant of Ottawa, the nestor of the Canadian Medical, had read a report on serum therapy in 1861 in which he recalled that in that year he had recorded good effects from the employment of ordinary vaccine lymph in the treatment of blood poisoning, Dr. Friedmann gave his address. The principles upon which his treatment are based are probably well known to the medical profession throughout the United States, so well has the Berlin physician been advertised from all points of view, and it would therefore be superfluous to quote his address. Suffice it to say that it seemed to be an admirably clear and lucid exposition of his principles. However, a few words here will not be out of place to explain the standpoint upon which three medical scientific bodies in Canada concluded that it would be in the best interests of the medical profession and the public to invite Dr. Friedmann to give demonstrations of his treatment. As a result of the wholesale advertising of Dr. Friedmann undertaken by the lay press and aggravated by the position taken by the medical profession of this country, however correct it may have been, all those suffering from tuberculosis were anxious to be treated and were thrown into a state of disquietude by their inability to obtain decided information on the point. Especially were sanatorium and dispensary physicians and those interested in the fight against tuberculosis placed in a most unenviable position. Accordingly, as this was the situation, in order to relieve this unrest, so dangerous to sufferers from tuberculosis, and to convince the public that the medical profession was not opposed to the discovery of a means of cure, it appeared that the wisest policy would be to offer Dr. Friedmann every facility for conducting his demonstrations under such conditions that there could be no doubt of the genuineness of the tests nor of the results obtained. Consequently the Royal Edward Institute of Montreal, the National Association for the Prevention of Tuberculosis and the University of Toronto decided to invite Dr. Friedmann to give demonstrations. It may be said that at Dr. Friedmann's demonstrations at the General Hospital, Ottawa, during the meeting more than one hundred and fifty medical men were present, including the leading authorities on tuberculosis in Canada.

The program of the meeting was as follows: Address of welcome by His Worship, Mayor Ellis; executive report presented by the secretary of the Association, Dr. George D. Porter; address of the president, Hon. Adam Beck; address by Hon. Martin Burrell, Minister of Agriculture; "Report on Serum Therapy in 1861," by Sir James Grant; "What the Daughters of the Empire Are Doing Towards the Prevention of Tuberculosis," by Mrs. Albert E. Gooderham, regent of the Imperial Order of the Daughters of the Empire; address by Dr. von Frederich Franz Friedmann of Berlin; formal opening of the Ottawa new sanatorium, the gift of the Hon. George H. Derby, by H. R. H., the Duke of Connaught; "How the Municipality May Best Deal with Tuberculosis," Dr. Chas. O. Hastings, medical health officer of the city of Toronto; "Some Newer Features of the Anti-Tuberculosis Campaign," Dr. A. J. Richer, Ste. Agathe, Que; "Tuberculosis in Childhood," Dr. J. H. Elliott, Toronto; "Tuberculin in Dispensary Treatment," Dr. E. S. Harding, Montreal; "The Tuberculosis Problem in Ontario," Dr. J. W. S. McCullough, chief health officer of Ontario.

The report of the able secretary of the association, Dr. G. D. Porter, Toronto, contained many interesting facts. Attention was drawn to the excellent progress that is being made in Canada in the campaign against tuberculosis. In Ontario, for instance, the new Health Act making tuberculosis a notifiable disease is a long step in advance. Nova Scotia, however, promises the most advanced legislation of all the provinces by a bill which will provide for some four new institutions for advanced cases, besides a maintenance allowance. The dispensaries in the larger cities scattered throughout the country are providing excellent agencies for controlling tuberculosis. It is pointed out that the most promising and recent feature of the campaign in Canada is the greater interest taken in the children. The open air schools, preventoria, and children's clinics are the latest developments.

The annual meeting of the Canadian Medical Association will take place in London, Ontario, from June 24 to 27 under the presidency of Dr. H. A. MacCallum. London is one of the most picturesque cities in Canada and for Canada easily accessible. A full program has been arranged. On June 26 two symposia will be held, one on diseases of the stomach, the discussion on which will be led by Dr. Alexander McPhedran, Toronto, the other on the thyroid led by Dr. A. J. Ochsner, Chicago. On the last day clinics will be conducted, the medical by Dr. Frank Billings and the surgical by Dr. John Murphy, Chicago. The addresses in surgery and medicine will be given respectively by Dr. Alexander Hutchison, Montreal, and Dr. L. F. Barker of Johns Hopkins University.

1. Localized Osteomyelitis of the Long Bones. C. C. Simmons.
2. Infections of the Upper Urinary Tract in Infancy and Childhood. R. M. Green.
3. The Views of Plato and Freud on the Etiology and Treatment of Hysteria: A Comparison and Critical Study. J. W. Courtney.

1. **Localized Osteomyelitis of the Long Bones.**—C. C. Simmons concludes that a mild acute localized osteomyelitis is often overlooked in its early stages, but when recognized and treated promptly recovery usually occurs in a few weeks. It makes little difference what type of operation is performed in the subacute cases, or cases of less than one year's duration, if it is thorough. The results are almost uniformly good. In the chronic, long-standing cases of bone abscess operations such as are performed in the earlier cases with success often give unsatisfactory results, as the endosteum is not capable of filling in the defect. No definite rule as to the type of operation can be laid down, but each case should be considered individually. When possible it would seem best to obliterate the cavity with living tissue flaps.

2. **Infections of Upper Urinary Tract in Children.**—R. M. Green states that: 1. In infants and children infections of the upper urinary tract, though infrequent, are likely to occur without adequate apparent antecedent cause. 2. Their onset is acute, their clinical picture is definite, and their recognition is often missed on account of their simulation of other infectious conditions. 3. Their two most usual forms are acute pyelitis and acute inflammatory nephritis. 4. The latter is most usually hematogenous in origin, the former probably proceeds by lymphatic extension from the intestine. 5. Predisposing causes are calculi, constipation, phimosis, anal fissures, and foci of infection elsewhere. 6. The classical signs of both are pyrexia, pyuria, and tenderness in the costovertebral angle. 7. The differential diagnosis depends on the examination of the urine. 8. The treatment consists in rest, milk diet, aqueous diuresis, moderate catharsis, urotropin with sodium benzoate, potassium citrate, or vaccine; in obstinate cases surgery to be resorted to only as a final measure.

3. **A Comparison of Plato's and of Freud's Theories of Hysteria.**—J. W. Courtney states that the essential features of Plato's and of Freud's theories are identical. Plato regarded the uterus as an animal which desires ardently to engender children. When it remains sterile for a long time after puberty, it endures this state with difficulty; it grows angry, rushes here and there through the body, causing either a globulus hystericus, a syncopal attack, or some other of the well-known hysterical manifestations. There are mental and emotional attributes ascribed by Plato to the uterus, and considered by him as the *vis a tergo*, which impel it upon its course. These attributes consist, on the one hand, of intense strivings, desires, and impulses on the part of the uterus to get itself fecundated and, on the other hand, of anger and other violent emotions aroused by delay or failure in the accomplishment of its designs. Freud simply shifts the above-mentioned attributes to their real sphere—the mind—and assumes an unconscious but stormy conflict among them as the cause of the outbreak of hysterical symptoms. To paraphrase the language of the Freudian pathology, there is waged in the mind of the victim of hysteria a conflict between two groups of ideas or mental processes which cannot be brought into harmony with each other. One complex of mental processes is, for some reason or other, of such a kind as to be inacceptable to the main body of the personality. The personality fails to assimilate it, will have nothing to do with it, tries to forget it, to submerge, to repress it. The repressed complex then takes on an automatic existence and acts as an irritating foreign body in the same way as any foreign body that has not been absorbed. Modern pathology is in itself a sufficient refutation of the etiological portion of Plato's theory. A very little close reasoning should serve to dispose of Freud's. The author's first objection to it is that it is absolutely arbitrary, in that it takes into account one element only of the many which compose that very complex product called personality. His second objection is that it is entirely illogical. It looks upon the symptoms of hysteria as voluntary on the part of the sufferer, *i.e.* a sort of compromise between unconscious sexual desire, longing and striving, and the repressive activities of a likewise unconscious mind. Hence, it asks us to believe that a voluntary act may at the same time be an unconscious one—in other words, that the will can operate without the conscious mind being aware of its operations. There are numerous other objections to the theory. One of these is to the effect that it locates the patient's trouble entirely within the realm of ideation and emotion absolutely without regard for the fact that the way human beings feel, talk, and act is but a reflection of organic sensation. In other words, it deals with the language, actions, and emotions of the psychoneurotic quota of humanity as a pure abstraction, without regard for their organic source.

9. Chronic Nephritis. G. Parker.
10. Edema of the Glottis. G. Kirby Collier.

1. **Hematuria.**—V. C. Pedersen points out the great importance and the grave possibilities of even minute degrees of urogenital hemorrhage. No bleeding is so scanty, but that it merits immediate and prompt investigation, because it may be the earliest sign of conditions essentially progressive and incurable excepting with the aid of surgical intervention practically at the moment of the earliest possible diagnosis. Such intervention may be removal of the offending lesion or at least adequate and energetic, well-balanced treatment. The rule to follow is, therefore, that any hematuria must be traced to its source and cause without delay.

2. **Shoulder and Arm Paralysis of Poliomyelitis.**—B. Barkow notes that holding the humeral head in contact with the glenoid cavity by artificial suspension of the humerus from the acromion fulfills at once one of the chief indications in the treatment of the deltoid and arm type of residual paralysis. Arm weight, normally sustained by the shoulder muscles and capsular ligament, then becomes

transferred to the scapula. This procedure removes the arm weight from the paralyzed muscles, thereby eliminating one of the main obstacles to improvement or recovery. The plan proposes the insertion of specially prepared silk strands in tunnels drilled through the acromion and head of the humerus; these, tied on top of the acromion, hold the humeral head close to its articulation. The drag is at once removed from the deltoid muscle and joint capsule, as shown by obliteration of the depression below the acromion.

3. **Anomalies in Cardiac Rhythm.**—T. Howard notes that the least significant type of cardiac irregularity, known as sinus arrhythmia, or youthful irregularity, is actually a mere exaggeration of certain normal variations in the heart's rate. Extra systole denotes a definite cardiac involvement, though not always an irrevocable damage. The most serious form of arrhythmia has been known by many names, as absolute or perpetual arrhythmia, disorderly rhythms, delirium cordis, nodal rhythm, etc. It is readily recognized, as the beats follow each other in most haphazard fashion, large and small, long and short, all jumbled in together. It has been shown that the underlying condition is one of auricular fibrillation. The chief importance of the latter from the therapeutic viewpoint is the remarkably beneficial effect which digitalis exerts in this condition. Heart block may or may not present an irregular pulse. The pulsus alternans consist of a series of alternating large and small beats, the time being regular, which obviously should be distinguished from a pulsus bigeminus in which each beat is followed by a pause. The pulsus alternans is due to an insufficiency of the contractile power of the heart. The cause of paroxyomal tachycardia is still veiled in obscurity.

4. **The Travels of a Nail.**—G. Rosenbaum reports the case of a child who swallowed a long wire nail. A series of six radiograms were taken. All told, the nail was in the alimentary tract fourteen days. Four days it lodged in the stomach and six days were required to complete the journey through the small intestines, and the remaining four days for its passage through the large intestines. The child had daily evacuations during this period, and, while it was quite restless during its stay in the ward, it was in no sense ill. The temperature never rose above normal.

5. **Paraurethræ.**—J. L. Herman states that congenital doubling of the male urethra does not occur in the absence of double penis. Double urethra in the female has been observed in association with double bladder, and Furst reports a case of double female urethra unassociated with any malformation of the urinary bladder. The latter is the only instance of this abnormality in the literature, the authenticity of which has gone unchallenged. Accessory canals of the penis, except fistulæ, the result of cloacal defects and urinary fistulæ of the penile urethra, as a rule demand no treatment if uncomplicated by a Neisserian or other infection. Infection of the urethra is usually, but not always, associated with infection of the abnormal canal and either may be the source of infection to the other.

6. **Fibromyoma Uteri.**—W. P. Healy concludes that uterine fibromyomata are very common. Heart murmurs with slight hypertrophy seem to occur more often than in other conditions. The lesion is not endocardial, but myocardial. Operation is not indicated unless the tumors are producing symptoms likely to interfere with the patient's health.

7. **Carcinoma of the Stomach.**—J. V. O'Connor notes that there is a tendency among physicians to make a diagnosis of indigestion or some other condition, without first trying to satisfy themselves that something more serious does not exist. If there were more early cases submitted for operation, the mortality following the operation for carcinoma of the stomach would be lessened, especially in those cases of slow growth. When the tendency toward making a too rapid and careless diagnosis no longer exists or is greatly diminished, one can look forward to a lower mortality following such operations as pylorectomy, and partial or complete gestrectomy.

8. **The Internal Treatment of Nephritic Diseases.**—H. Strauss states that if one assumes that uremia in many cases is no more than autointoxication by retention, we must arrive at the deduction that we should dilute the toxins and try to wash them out of the body. Furthermore, one should not allow any alimentation which could be considered as a cause of autointoxication, or one should reduce it to a minimum. Meat, especially, seems to be noxious. The author believes in a general diminution of albuminous alimentation, but up to such a degree only that the heart nourishment does not suffer. It has been proved that an adequate exhibition of liquids aids in expelling the sediments of metabolism. It is much more desirable to combat the danger of poisoning than to prevent heart attacks. In applying strict cures, *i.e.* cures in which the amount of salt should not exceed 2.5 grammes per diem, the milk allowed to the patient must also be taken into consideration, while saltless butter only should be allowed. Small doses of digitalis possess a special effect upon the kidneys, besides being a cardiac tonic. For that reason it is advisable to employ a preparation which is a combination of digitalis and theobromine, for the purpose of freeing the body from water. Sudorific treatments, which formerly possessed a great reputation in combating uremia and dropsy, have lost a great deal of their prestige through late researches.

9. **Anemia in Chronic Nephritis.**—G. Parker reports a case which simply illustrates the severe degree to which anemia in nephritis may proceed. The viscosity of the blood was practically nil, and the bloodvessel tone must have been of a very low order. The blood stains on white cloths were extremely pale. Doubtless the two factors, namely, injured and permeable vessel walls of poor tone and loss of clotting power in the blood itself, each participated largely in the production of hemorrhage.

10. **Edema of the Glottis Associated with Epilepsy.**—G. K. Collier reports a fatal case of this condition. Tracheotomy had unfortunately been decided upon too late, after ineffectual attempts had been made to perform intubation. Pulmonary edema, accompanying serial epilepsy, status epilepticus, and even single seizures, is frequently met with, but the case herewith cited, in which edema of the glottis occurred, is unusual. The mechanical theory, in explanation of pulmonary edema, can be readily accepted in cases of epilepsy where there is a marked increase of capillary tension produced by an excess of blood from the right heart. The infectious and the noninfectious forms are seen, also the secondary forms, due to tuberculosis, syphilis, carcinoma, typhoid fever, scarlet fever, measles, and smallpox, and those following valvular disease of the heart and nephritis.

1. **Mycetoma.**—R. L. Sutton states that, clinically, mycetoma can be divided into three varieties, the yellow or ochroid, the black and the red, so named from the color of the small granules suspended in the oily seropurulent discharge from the sinuses. The ochroid is the most common form and the red is extremely rare. Bacteriologically, the consensus of opinion favors the view that the two common forms, the yellow and the black, are due to different organisms though they are quite similar. The often repeated statement that the yellow variety is an actinomycosis is not supported by the weight of evidence in the literature and it is positively disproved by the results of Musgrave and Clegg in the Philippines. These authors think it probable that all types of mycetoma are due to streptothrix infection, but whether all forms are caused by the same organism or whether there is more than one species involved cannot be positively asserted.

3. **Steam Sterilization.**—M. Rubner points out that the beneficial influence of steam disinfection is exercised only on objects with large open pores and the power by which it enters is the difference between the specific gravity of the steam and that of the air in the pores of the materials to be disinfected. This is why the steam should be introduced into the apparatus from the top and the steam and air escape at the bottom, but this explanation is not quite sufficient; there may be some parts where the resistance is too great for it to penetrate and articles should not be too tightly packed when subjected to the heating. The action on the microbes takes place first by coagulation of the protein and the amount of water and salt contained in the organism aids the coagulation. It is the lesser amount of these substances in the spores that makes them more resistant. Steam at 100° C. exercises a chemically destructive action, also, and the greater the saturation of the steam the greater is its destructive power on the germs. The discovery of formaldehyde meant a great step in advance for the doctrine of steam disinfection, and the author gives an account of his experiments with steam formaldehyde disinfection. By it even the most delicate objects are not injured, and the process has been developed to an extent that large apparatuses have been made in which whole ambulances can be disinfected. It is even possible to construct one large enough to disinfect whole railway cars.

4. **A Danger in the Use of Antimeningitis Serum.**—S. P. Kramer reports six cases of death coming on with respiratory paralysis a few minutes after the injection of antimeningitic serum and two cases in which the respiratory paralysis was relieved by artificial respiration, the children dying later from the disease. In a previous article he had reported cases of respiratory paralysis following the lumbar injection of cocaine and from the similarity of the cases here reported he considers these latter to be of toxic origin. He quotes from his experiments on dogs in which it was shown that methylene-blue injected into the subdural space could find its way through the central canal and, aided by the ciliated epithelium, into the ventricular system of the brain. He performed the experiment of injecting antimeningitis serum and a solution of tricresol of the strength used in the serum, into the subdural space. There resulted respiratory paralysis and the author concludes that the tricresol is the offending agent and that serum containing 0.5 per cent. of tricresol cannot be safely used for injections in young children.

7. **Alcohol Injection into the Gasserian Ganglion.**—J. Grinker states that the greatest advance in trifacial neuralgia was made when Schlösser, a Munich ophthalmologist, announced his method of injecting alcohol into the branches of the trigeminus at their exit from the skull. With the comparatively easy technique discovered by Levy and Badouin this has become a distinct addition to the physician's therapeutic armamentarium. In some cases, however, this fails and a less peripheral operation is demanded. Gasserectomy is a serious operation and necessarily one of last resort. As alcohol had shown its efficacy in the peripheral injection, it has been sought to introduced it into the ganglion itself to avoid the more dangerous method of extirpation. To F. Härtel of Biers clinic belongs the credit of having worked out such a method. The author has had the opportunity of observing Härtel's technique and has employed it once in his own practice in a case which he reports.

8. **Puzzling Gastrointestinal Symptoms.**—E. D. Watkins reports the case of a boy of 7 years reared under the best hygienic conditions in whom there developed symptoms both peculiar and puzzling. Although fed on breast milk up to 18 months the patient had almost continuous dysentery which persisted for five years. Frequent vomiting occurred. At 2 years so-called "cyclic vomiting" began. This was ushered in with a mild tonsillitis after exposure to cold and wet. All anti-emetics failed. Constipation and distention accompanied the vomiting and enemata were necessary on account of stomach sensitiveness. Marked emaciation followed each violent attack, which occurred about four times a year. Clinical findings were unimportant. The last and worst attack came on in December, 1912, and lasted two weeks. Normal saline per rectum was the only thing that produced any good effect on vomiting. An organism resembling *Entameba histolytica* was found in the stools. Treatment was begun at once with colonic irrigations of silver phosphate, copper phosphate, and quinine phosphate. Improvement soon followed, which led to the belief that the periodical attacks of vomiting were due to the presence of the ameba.

1. **Surgery of Malignant Disease of Mouth and Pharynx.**—W. Trotter states that an important question to be decided in every case is whether the disease is to be attacked in a two-stage or a one-stage operation, and as a corollary whether the gland operation or that on the primary growth should be done first. In the great majority of cases there can be no doubt that the two-stage operation is necessary. The attempt to accomplish in one sitting the two very complex procedures can only lead to excessive danger to the patient or a risk of incomplete removal of the disease. The only exception to this rule is in the case of epilaryngeal tumors. Here the primary growth cannot be attacked until the glands have been removed, and on account of the situation of the growth the gland operation even cannot be done with any safety without a preliminary tracheotomy. As to the sequence of the two stages the following general rules are those upon which the author decides. If the primary growth is in such a situation and of such size that rapid union can be obtained after removal of it, then the first stage should be on the primary growth and the second on the glands. This is chiefly in early tongue cases. In such cases the whole treatment can usually be completed in a fortnight. Where the primary growth is such that rapid union is not probable (*e.g.* where the jaw has to be divided), the gland operation should be done first. This has its special disadvantage in the danger of pneumonia of an extensive neck operation when there is an ulcerating growth in the mouth, but the special advantage is that the gland operation is much easier when done first. Where the glands

hinder access to the primary growth three courses are possible: (a) Gland operation first (glands very large). Tracheotomy is usually necessary. (b) Primary growth and partial gland operation first (usually tonsillar cases). (c) Single-stage operation (epilaryngeal cases). Where the primary growth or gland mass is of uncertain operability the one which is the more doubtful should be attacked first. The essential steps of the operation on the primary growth are as follows: Every operation for removal of a tumor must begin with a definite stage devoted to obtaining access to the mucous surface of the tumor. This is usually a perfectly formal anatomical procedure which applies to all cases when the same region is affected. As soon as the tumor is fully exposed a systematic attempt must be made to disinfect the region, and during the subsequent removal of the growth every effort must be made to preserve the wound from contamination. The surface of the ulcer should be cauterized, the surrounding mucous membrane cleansed with alcohol and the region of the tumor packed off so that mucus is prevented from flowing into the wound. The tumor is then excised with the size and form of surrounding margin dictated by the nature of the case. The wound from which the tumor has been taken must be closed by suture and such other plastic procedures as are necessary should be carried out.

3. **Vaccination with Living Microorganisms.**—W. Broughton-Alcock records the favorable results that he obtained with the use of sensitized living vaccines. He conducted his research as an assistant to Professor Besredka in Metchnikoff's laboratory at the Pasteur Institute. The success attending the use of sensitized living typhoid vaccines has already been published. The author's recent efforts have been directed against infections by various strains of staphylococci and streptococci; and against those due to the gonococcus. The sensitization of the bacteria is effected by the use of an antiserum. For streptococci the antistreptococcus serum as prepared at the Pasteur Institute is used. The antigonococcal and antistaphylococcal sera are prepared in the goat. For the gonococci the author leaves them with the antiserum 12-24 hours at 37° C. and 12-24 hours in his room. For the staphylococci and streptococci he leaves them with their respective antiserum for one hour at 37° C. and all night at 0° C. The quantity of serum depends on its richness in sensitizing substances. In cases of gonorrheal orchitis and epididymitis most of the patients were free from pain after the first injection. In four cases of gonorrheal rheumatism the results were remarkable. After the first injection and within forty-eight hours acutely inflamed joints that one could barely touch, in one case of fifteen days' duration, were freely movable without pain. The exudation disappeared in three days. Vertebral pain and painful nonsuppurating ganglions were also rapidly relieved by the first injection. The cure persisted when patients were seen one month later. The only instances in which there was not complete relief within a week were those of subacute tendinitis without exudation. They necessitated at least one to three weeks' injection treatment. The author found, however, no advantage of the living sensitized gonococci over the dead organisms. In sixty cases of staphylococcus infection treated with sensitized living staphylococci, there was no instance of failure to markedly ameliorate the condition.

4. **A New Test for Diacetic Acid.**—W. H. Hurtley describes this new test as follows: To 10 c.c. of the urine add 2.5 c.c. of concentrated hydrochloric acid and 1 c.c. of a 1 per cent. solution of sodium nitrite; shake and allow to stand two minutes. Now add 15 c.c. of strong ammonia, followed by 5 c.c. of a 10 per cent. solution of ferrous sulphate, or a solution of ferrous chloride of equivalent strength (2 grm. of iron in 100 c.c.). Shake up, pour into a 50 c.c. Nessler glass, and allow to stand undisturbed. It is not advisable to filter. A beautiful violet or purple color is produced. The reaction is a slow one, and the speed at which the color develops depends on the concentration of the acetoacetic acid in the urine; the color deepens for several hours after its first appearance. The explanation which the author offers of the test is that the acetoacetic acid is converted by the nitrous acid into isonitrosoacetone, which forms a salt with the ammonia; the ferrous salt then produces a purple-colored salt from the ammonia salt by double decomposition. That isonitrosoacetone in alkaline solution forms colored salts on the addition of ferrous sulphate was first shown by Martha A. Whiteley. The test has been tried on several normal and on a large number of pathological urines, and on the urine of patients taking salicylic preparations; but only urines which react with the other tests for acetoacetic acid give this test. Acetone does not give the test, but an aqueous solution of ethyl acetoacetate gives a pure blue color—not a purple—and it only gives the blue color when much more nitrite is used than is prescribed in the test above. As regards delicacy, the test, when performed on a solution of sodium acetoacetate, prepared in the way already described, shows at a dilution of 1 part of acetoacetic acid in 50,000 parts of solution.

1. **Malingering and Valetudinarianism.**—Byrom Bramwell draws a distinction between malingering, the conscious and deliberate simulation of disease or exaggeration of symptoms and valetudinarianism, the unconscious or subconscious simulation of disease or exaggeration of symptoms. (1) There are cases in which perfectly healthy persons feign disease, induce disease, or claim that they have received an injury and profess to be suffering from symptoms due to that injury. (2) There are cases in which after an accident or injury the results or remains of previous disease are said to be due to the injury. (3) Cases occur in which patients who are suffering from the effects of an accident or injury or from ordinary illness not due to accident or injury, exaggerate their symptoms, or do not get as well as they should be expected to do, but continue to suffer and go on claiming compensation.

5. **Cutaneous Indications of Alimentary Toxemia.**—J. Galloway states that the outward manifestaitons group themselves easily in four main categories: (1) Those resulting from disturbances of the blood vessels which disappear leaving no permanent trace. In this category may be grouped the varieties of urticaria, evanescent or of long duration, and the types of erythema, including exudative and vesicating forms. (2) Morbid conditions in which an inflammatory lesion progresses to actual infiltration of the integuments with cellular elements and terminating in persisting deformity such as dilatation of blood vessels, atrophy, persistent dermatitis, ulceration, and scarring. (3) Purpura in its different forms—punctate, diffuse, and often

associated with other hemorrhagic manifestations. (4) Pigmentation due to increase or abnormal distribution of pigments closely related to those of the normal type, such as melanin, or in other cases to pigments more recently derived from hemoglobin and due to hemolysis resulting from the circulating intestinal toxins.

6. **Chronic Intestinal Stasis.**—A. F. Hertz reaches the following conclusions: When precautions are taken to prevent errors in diagnosis, it is found that intestinal stasis never leads to gastric stasis. Intestinal stasis does not lead to duodenal kinking, dilatation, or ulceration, and duodenal ulcers are associated with an unusually rapid passage of chyme out of the stomach and through the whole of the small intestine. Iliac stasis is a normal phenomenon and results from the action of the ileocecal sphincter. Iliac kinks are comparatively rare, and do not directly increase the normal iliac stasis. The normal iliac stasis may be increased by spasm or absence of relaxation of the ileocecal sphincter, as a result of disease in the neighborhood of the cecum, including perhaps iliac kinks. Ptosis of the intestines does not lead to stasis, except in rare instances, at the splenic flexure, a pelvic cecum and a pelvic transverse colon being compatible with perfect health and normal intestinal action. In most cases of constipation a single part of the bowel, such as the rectum, pelvic colon, ascending colon, or splenic flexure, is alone involved, and treatment should therefore be directed to the affected part only. In those cases in which the whole of the colon is involved medical treatment almost invariably succeeds, but when it does not, ileosigmoidostomy, with or without colectomy, is indicated.

8. **Puerperal Eclampsia.**—R. A. Gibbons concludes that in spite of all the labor which has been spent upon investigation, we know of nothing which we can definitely state gives rise to the disease, although everything seems to point to a poison circulating in the blood as being the cause. Statistics recently gathered show that the best treatment is that of rapidly emptying the uterus—by whatever means this may be most safely accomplished—after the first few convulsions; that is to say, without indefinite delay. The woman and the child are thereby given the best chance of life; in fact, the maternal mortality has been lowered in the hands of some to under 5 per cent. The greater the delay in carrying out this treatment after the onset of the first convulsion, the greater will be the danger. The time is not far distant when, by continued research, the knowledge of the actual cause will provide one with a weapon to surely prevent the onset of this disease, and relieve the accoucheur of the future of one of the most terrible complications of the lying-in room.

10. **Prevention versus Cure.**—C. J. Whitby states that the time has long passed when it was customary to think of disease as a something extra-natural—a visitation of the invisible—to be combated by amulets and spells. But the traces of this conception have lingered until quite recently in the minds of even the most enlightened. Now they are well-nigh obliterated; pathologist and physiologist, tunnelling in opposite directions, have met on common ground. We think of disease in terms of health, and of health in terms of disease. Health seems to be in the main conditioned by the functional equilibrium of various glands; and since now one, now another of these glands takes the lead and evokes the antagonism of the others as the rhythm of growth and development proceeds, it is hardly too much to say that, from the chemico-vital aspect, a series of autointoxications, followed by slowly acquired immunities—that is to say, of illnesses and recoveries—is the normal course of events. Dentition, puberty, adolescence, menstruation, sex life, the climacteric, afford, even in the healthiest individuals, common ground for the physiologist and the pathologist. There is a pathological factor in all health, and a physiological in all disease: the two conditions overlap, and merge into one another by imperceptible gradations. So preventive and curative medicine meet when a disease due to functional inhibition of a given set of glands is treated by the administration of full doses of the missing internal secretion, thus affording immediate relief of symptoms as well as the interval of rest required by the damaged organs. Much of modern surgery belongs equally to the preventive and curative spheres.

12. **Unusual Fertility in Syphilitic Parents.**—H. F. Watson reports the case of a family in which the father, aged 29, and the mother, aged 21, both showed evidence of syphilis, although they denied ever having had this disease. In the course of twenty-two months there were three multiple pregnancies, with a total of six children. The parents and the children all gave a positive Wassermann reaction. The manifestations of syphilis appeared to be more severe with the successive pregnancies. There were no abortions.

14. **Tetany in Acute Suppurative Appendicitis.**—B. Hughes notes that the condition of tetany occurring in adults is not altogether common. Perhaps the commonest conditions with which it is associated are gastro-intestinal disorders (gastritis, dilatation of the stomach, and intestinal parasites), pregnancy, and operations upon the thyroid gland; sometimes it complicates the infectious fevers, notably typhoid. Less rarely still is it associated with certain poisons taken into the system, such poisons being lead, alcohol, and ergot. It is said to complicate cerebral and cerebellar tumor, but this must be extremely rare. Tetany associated with surgical operation upon the thyroid gland is a very rare condition. It has been said that tetany occurring in this last-named condition is due to removal of the parathyroid bodies, and experimental work seems to lend support to this statement. The author reports a case of tetany associated with acute suppurative appendicitis.

*April* 14, 1913.

**Treatment of Progressive Paralysis.**—Westphal asks if this affection is ever curable or self-limited. Apparent recoveries are commonly interpreted as latent cases. Tuczek now admits that his well-known "cure" is open to doubt. Alzheimer has shown that irreparable damage is caused during the earliest stages of the affection, and agrees with Spielmeyer that we can, therefore, obtain no anatomical proof of a cure. On the other hand, no one can deny that a lifelong arrest represents a clinical cure. In theory such results are possible chiefly in cases in which an early diagnosis is made; and the frequency with which neurasthenia precedes paralysis furnishes us with a hint for early diagnosis and treatment. But while the true neurasthenic seeks the physician upon the first appearance of his symptoms the future paralytic pursues exactly the opposite course and does not reach consultation until brought to the practitioner by his friends. If the diagnosis between the two maladies is then doubtful a positive Wassermann may decide the matter, although there is no reason why any syphilitic may not be a neurasthenic and *vice versa*. With diagnosis made sufficiently early the patient should, for form's sake, receive a vigorous Hg and KI cure. This usually cures and eliminates pseudoparalysis so called, i. e. early cerebrospinal syphilis. While salvarsan not infrequently causes the Wassermann reaction to become negative it is powerless against the disease. After enumerating all the newer resources which have been said to possess more or less power over the disease (tuberculin, nuclein, etc.) the author touches upon Noguchi's recent demonstration of the spirochete in the cerebral cortex in general paralysis. This discovery appears to imply that the microorganism undergoes some sort of mutation which cannot be attacked by the salvarsans.

**Hemolytic Icterus.**—Mosse asks what diseases most require differentiation from this affection otherwise known as "chronic acholuric icterus with splenomegaly." Five types of disease are mentioned as requiring differentiation from hemolytic icterus and of course from one another. The first is pernicious anemia, in a number of cases of which diagnosis has been difficult. Next is mentioned Gilbert's familial cholemia, regarded by some as identical with hemolytic icterus. Chalier, a recent writer, regards the former as a mild type of the latter, and points out well-marked dissimilarities. Third comes Banti's disease, including its hemolytic form. Fourth in order is polyglobulia, both of the compensatory and cyanotic types. Finally is added the Gaucher type of splenomegaly, because some of the recorded cases might have been termed hemolytic icterus.

**Action of Phosphorized Oil in Rickets.**—Gessner seeks to explain the beneficent effects in rickets of phosphorized cod-liver oil as follows: The disease is preeminently one of metabolism in which the normal transformation of fetal red bone marrow into the permanent, yellow fatty marrow does not occur. The fat hunger of the affected organism, however produced, cannot be satisfied by the artificial milk mixtures, however closely these correspond isodynamically with mother's milk. Since phosphorized cod liver oil apparently corrects the metabolic defect and puts a stop to the demineralization of the body, the rationale should lie in part in the ready assimilability and utilization of cod-liver oil and partly in the general stimulation of metabolism by the phosphorus component.

**Physiological Surgery.**—Under this title Klapp of Prof. Bier's clinic mentions with approbation Krehl's well-known work on pathological physiology and states that it should be supplemented by a work on physiological surgery. Physiological therapeutics is of course largely surgical in character, and naturally the physiological idea should be omnipresent in all therapeutics. From this viewpoint a great deal of treatment of approved value is distinctly unphysiological. Under this head the author includes asepsis. As illustration he cites peritoneal interventions. One thing is certain, to wit, whatever else we do, we must maintain physiological conditions as far as possible. Rehn states that whenever the intraabdominal pressure has been disturbed we must seek to restore it. This necessitates the closure of all intraabdominal incisions. The author asserts, on the other hand, that this is a matter of subordinate significance. He claims that closure of these openings makes for recovery, not only because of restored pressure conditions, but also for the reason that other physiological factors are favored—avoidance of lowered temperatures, and of loss of water, while the normal peristaltic motion of the intestines is maintained. All this amounts simply to the dictum that if we open the peritoneum for any purpose it is physiological to close it as soon as the desired result is attained or found unattainable. In general making good of losses is at the bottom of physiological surgery, for example, in all kinds of plastic and artificial substitution.

**Quadruplets.**—Hauser relates a case of this relatively rare occurrence, which may be summed up as follows: The midwife who had attended the case brought to the author a quadruplet placenta. Labor had been so rapid that no time was allowed to summon a medical man. The mother was a Pole, aged 29, V-para, all previous births single. As gravida on this occasion she had presented an early and unusually large circumference of body, so that she had suffered considerably and had been nearly unable to do any work for three weeks before delivery. Pains were strong, patient well able to bear down, and six and one-half hours after beginning of labor a child was born. Twenty minutes later a second one was extracted in incomplete foot presentation. After a short cessation of pains a third child arrived within another hour as a complete breech case, while one hour later the fourth child was born after the same presentation. Despite the great distention of the uterus the afterbirth period was brief and the large placenta was successfully expelled entire. The first two children were male and the last two female. The author found that the mother was a normal, powerful woman, with no physical stigmata. The generative organs and accessories were normal throughout and there was no history in the families of multiple birth. The children all perished within 25 hours. They had the status of prematures (28-30 weeks) and some no doubt could have been saved in incubators—two or perhaps three. Having looked into the literature of the subject the author gives some conclusions which affect quadruplets. First, mothers of quadruplets are older than mothers of triplets just as mothers of triplets exceed in age mothers of twins. Second, the number of primiparæ who give birth to more than one child diminishes with the increasing number of children at a birth. Third, mothers of quadruplets are nearly all multiparæ who have borne six or more children; while mothers of twins and triplets have usually borne from two to five times. However, the number of quadruplet births is really too small to be available for statistics.

**General Management of Infectious Diseases.**—Grober believes that generally speaking the prognosis of infectious diseases under modern treatment has improved. The factors which have brought about this result are numerous. Taking them more or less at random they comprise among others certain sedatives and hypnotics which have supplanted the narcotic morphine, the intravenous administration of digitalis derivatives and adrenalin, antipyresis with drugs and hydrotherapy, citric acid and HCl lemonades as aids to appetite, improved technique in regard to feeding, especially in bringing up the calories, revolutionary technique in nursing the sick, specific antibacterial therapy, including partial solution of the carrier problems, antitoxin therapy (in diphtheria), chemotherapy (in syphilis), vaccinotherapy, etc. Naturally in all specific and quasi-specific plans of treatment prophylaxis enters into consideration and is usually of much greater purport than treatment. The author gives due credit to old empirical medicine for the modern use of drastics, diuretics, etc., in infections. The power of purgatives, notably calomel, in the early period of acute infections is as well recognized to-day as ever. Under diuresis as a resource against infections no one drug is mentioned, although the reader thinks at once of urotropin as filling the indication to-day. Drastics and diuretics are naturally regarded to-day as possible eliminators of bacteria.

**Eye Studies in German East Africa.**—Krusius concludes his article on this subject as follows: Cataract seemed common in both negroes and Hindoo aliens along the coast. In addition to the indigenous trachoma mentioned as fearfully prevalent in the interior numerous imported cases were also seen in the coast towns. Pneumococcus affections of the eye were strangely absent, although other pneumococcus diseases were prevalent. While so-called scrofulous affections in general are very rare, the ulcers of the cornea commonly associated with that condition were quite common. Recurrent fever, a spirillosis, appears often like syphilis to set up iridochoroiditis. Malaria also is suspected of being the cause of several lesions.

## Insurance Medicine.

**So-Called Heart Murmurs.**—Steiner writes in reference to the exaggerated importance accorded to cardiac murmurs—with all due deference to the cardinal significance of the latter as symptoms of actual disease. He illustrates the possibility of overvaluation of murmurs by two case histories. The general tendency of all medical examiners is to disqualify a prospective risk whenever a murmur is heard on the ground that no one can assert with certainty that the subject is not the victim of a valvular lesion. The manual of instruction used in such cases states plainly that however faint the murmur, and even after but one examination, the examiner must reject or postpone the applicant. There is only one exaction laid upon him, viz., he must be sure that the sound is of cardiac origin. Thus if the ordinary examination in standing posture is negative, the applicant must throw extra effort on his heart by prescribed exercises and further be examined lying down and with the stethoscope. The examiner may only postpone in the case of young subjects. These commands make it easy for the examiner, but no real service is rendered either to the company or the applicant. Collateral subjects and notably that of the functional capacity of the heart are ignored. When we treat a patient with cardiac trouble we have always in mind the test of efficiency, not the acoustic phenomena. Numerous distinguished clinicians may be quoted to this effect. Murmurs are not necessarily indicative of endocarditis. If truly valvular in origin they may be due either to muscular or nervous action upon the valves. The first case cited occurred in a young man who was well nourished and apparently in florid health. There was no history of disease worth mentioning. During examination for military service a "cardiac defect" was brought to light. The subject was active all day long on a truck farm, was not fatigued at night, and danced and rode a wheel without effort. The author's examination made after considerable physical exertion yielded a pulse of 68, respiration 9. There was heard, however, over the apex and replacing the first sound, a long drawn, blowing murmur. This was at once pronounced congenital in origin, and without the least influence on the economies of the heart. Should an applicant like the preceding be rejected outright? Recently the young man broke his leg, as the result of a severe accident; yet his nervous and muscular system showed not the least reaction. The second patient was a German-American, who traveled extensively for a large business house. Always in a state of psychic tension from the exactions of his business, he further sustained great pecuniary losses in the panic of 1907. While sojourning at Kissingen a cardiac murmur was discovered, and was heard by the patient himself with the autostethoscope. The organ itself gave no trouble whatever. The author heard an intensive murmur, propagated from the apex to all the valves. Despite the demands upon the patient's energy the pulse and respiration were but 64 and 16 respectively. There was a transitory emphysema pulmonum, and both this and the murmur are certain to yield to a period of rest. The murmur was doubtless of nervous origin, and technically would rank as initial insufficiency. In both the preceding cases there were no alterations in the cardiac chambers while the second pulmonal sound was normal. It was therefore impossible to estimate the degree of the defect. Compensatory states of the heart could be excluded. In support of his strictures on overvaluation of heart murmurs the author would further cite the statistics of survival of applicants rejected for "cardiac defects" (these naturally including actual lesions with compensation). These take cognizance of survival to 10, 15, 20, and 25 years.—*Blätter f. Vertrauensärzte d. Lebensversicherung, No.* 1, 1913.

**Decreased Mortality the Work of Insurance Companies.**—Dr. Eugene Lyman Fisk says the belief that the mortality-rate, among selected insurance lives, is a fixed quantity, obtains among many insurance men, notwithstanding much recent evidence to the contrary. In a medico-actuarial investigation, covering 43 American companies, a marked improvement was shown, from 1885 to 1890, among the younger-age groups, and a distinct deterioration among those over age 60. The death-rate throughout the civilized world has been falling, due, not to the increased span of life, but to the saving of lives in the younger-age groups, through the increased scientific knowledge of the prevention and control of communicable diseases. That science can lessen the death-rate from diseases caused through faulty living and the mere wear and tear of life, cannot be quetioned. This is the work of the insurance companies for the present and the future.—*Popular Science Monthly,* April, 1913.

**"The Man on the Street" and Health-Conservation Work.**—When approached on the subject of prolonging his life by adjusting himself to his environment, "the man on the street," otherwise the average careless liver, displays an uneasiness and some skepticism about the means required for materially increasing his span of life without surrendering some of the indulgencies, which, to him, make life worth living. Dr. Eugene L. Fisk says that such men must be taught that the lengthening of life by betterment of living, is not the niggardly hoarding of existence, without regard to its color, quality, or meaning, but a warfare against needless misery, preventable diseases, mental and physical inefficiency, and the pitiable handicaps, that not only shorten life, but take from it the color and satisfaction that make it worth living. The prolongation of life, through well-living, is the work of insurance companies through health-conservation, and justifies the financial expenditure. The work in hand is to make life more livable, through the joys of health and right-living and not through the fleshpots of our friend, the careless liver.—*Popular Science Monthly,* April, 1913.

**More Careful Examinations Needed.**—Dr. F. de Havilland Hall, in a meeting of the Medical Officers' Association for the discussion of "The Prevention of Fraud in Life Assurance," stated that it was not so much fraud of the patients as carelessness of the examiners that was the trouble. As a rule, the country examiners are too happy-go-lucky and the city examiners too rushed. It is not right to have the regular family physician also the medical examiner for life assurance, as awkward positions arise in this way which put the physician at a decided loss. The smallest troubles should be carefully looked into, especially that of "hoarseness," which so often means a tuberculosis or a beginning epithelioma of the larynx. Dr. Hall says that the medical examiner should take no account of the amounts the persons are insured for, but should make his examination of the applicant for a $500 policy with as much care as he would that of the $10,000 risk.

# Book Reviews.

Diseases of the Stomach, Intestines, and Pancreas. By Robert Coleman Kemp, M.D., Professor of Gastro-intestinal Diseases in the New York School of Clinical Medicine; late Gastroenterologist to the New York Red Cross Hospital; Gastrologist to the West Side German Dispensary; Consulting Physician, Gastrointestinal Diseases, to the Manhattan State Hospital; Member American Medical Association, Academy of Medicine, etc. With 388 illustrations, some in colors. Second Edition, revised and enlarged. Price, cloth, $6.50 net; half morocco, $8.00 net. Philadelphia and London W. B. Saunders Company, 1912.

The high standard which was established by this work when it first appeared two years ago is maintained in the present edition. Several new subjects have been added, including chapters on colon bacillus infection and on diseases of the pancreas. The section on duodenal ulcer has been rewritten. The section on visceral displacements is particularly full and satisfying, the mechanical methods of treatment available to the general practitioner being described in detail with the aid of many clear illustrations. Among other features of this edition are the endorsement of Chittenden's views on excessive protein diet, the discussion of typhoid fever and its intestinal complications, the dietetics of this disease and the view that excessive calorie values have been advocated, a chapter on diverticulitis, and a discussion on reflex gastrointestinal disturbances emanating from disease of the gall-bladder, appendix, and other organs. Attention may be called to the comprehensive manner in which the pancreas and its diseases are discussed, about 100 pages being devoted to this subject. There is an allotment of about 40 pages to the subject of simple duodenal ulcer. The illustrations in this work are particularly numerous and represent a high order of artistic merit. The methods of treatment are described in great detail and should be of distinct service to the general practitioner. The work represents one of the best of its kind that has appeared within recent years.

Physical Diagnosis. By Richard C. Cabot, M.D., Assistant Professor of Medicine in Harvard University. Fifth Edition. Revised and enlarged with 5 plates and 268 figures in the text. Price $3.00 net. New York: William Wood and Company, 1912.

The appearance of five editions of this work within a period of seven years is ample evidence of the popularity which it has achieved. The author has set a high standard for books on physical diagnosis, and none of the many volumes on this subject that have appeared with the past few years have approached this standard as closely as has the admirable work of Dr. Cabot. The skill of the mature teacher is discerned on every page, in the clearness and fullness of the subject matters, in the omission of non-essential and problematical details, and in the provision of illustrations that actually assist in the elucidation of the text. These illustrations are numerous, are well selected, and represent the best in the photographer's and printer's art. The author has continued the excellent plan of describing in a single section all the methods of getting information about any organ—methods both of the clinic and of the laboratory. It may be noted that the present edition has been thoroughly revised and enlarged, containing many important editions, such as the following: Sections on the phlegogram and the arteriogram; the recasting of the section on blood pressure and the arrhythmias, as well as on those on neoplasms of the lung and pleura, on subphrenic abscess and peptic ulcer. There is also a more extended description of the *x*-ray method of examination of the stomach.

Diseases of the Mouth. For Physicians, Dentists, Medical, and Dental Students. By Prof. Dr. F. Zinsser, Director of the Department of Dermatology at the City Hospital, Lindenburg; Dozent at the Academy for Practical Medicine, Cologne. Translated and edited by John Bethune Stein, M.D., Professor of Physiology at the New York College of Dentistry; late Instructor in Genitourinary Diseases at the College of Physicians and Surgeons (Medical Department of Columbia University), New York City. With 52 colored and 21 black and white illustrations. Price, $7.00. New York: Rebman Company, 1912.

This work is printed as a pictorial atlas of syphilitic and other lesions of the mouth, and aims to bring together the material that is scattered in the clinics of dermatology, laryngology, surgery, internal medicine, pediatrics, and dentistry. The introductory portion of the work consists of a short review of the subject of syphilis, and a description of the lesions of the mouth that resemble the lesions of secondary or tertiary syphilis. The illustrations consist of a series of 46 plates, comprising 52 superb colored and 21 black and white illustrations. These portray with a vividness and with almost the reality of the actual case, the various primary, secondary, and tertiary syphilitic lesions of the mouth and throat; the forms of stomatitis produced by mercury and other drugs; geographical tongue, tuberculosis of the mouth, etc. The dentist and dental student whose opportunities for the study of constitutional diseases presenting mouth lesions are limited, will find this volume a valuable guide, and so will the physician and the medical student. The practical importance of a knowledge of the differential diagnosis of lesions of the mouth is fully realized when one is confronted with a case presenting a suspicious sore on the tongue. Is a certain tonsillar patch syphilitic or is it the manifestation of a Plaut-Vincent angina? This is but one instance of many that may be recalled by the busy practitioner. A book of this kind enables one to survey in a short time the appearance of many different kinds of lesions. The work of the translator reveals his broad knowledge and sympathetic interest in the subject matter. He has made a number of additions to the text, such as the description of the luetin reaction in syphilis. The printing, binding, and artistic features of this book represent the best of the publisher's art and are strictly in keeping with the excellent manner in which the subject matter has been handled.

The International Medical Annual. A Year Book of Treatment and Practitioner's Index. Thirty-first Year. Price $3.50. New York: E. B. Treat & Company, 1913.

This annual, of which the years are becoming long, in the 1913 edition maintains its high standard. It is alphabetically arranged and thoroughly indexed and the subject matter is written by recognized authorities. In a concise form it presents up-to-date medicine and surgery, so that it supplies a valuable vade mecum to the busy practitioner. A beginning has been made in the present volume of a glossary of new terms, a useful addition when the many new words which have been introduced into medical literature during recent years are considered. The book is well printed, excellently illustrated and inexpensive and we have no hesitation in recommending it strongly to members of the medical profession.

Diseases of the Eyes. By C. Devereux Marshall, F.R.C.S., Surgeon to the Royal London (Moorfields) Ophthalmic Hospital and Ophthalmic Surgeon to the Victoria Hospital for Children, Chelsea. Fully illustrated. Price $3.75. London: University of London Press, 1913.

Mr. Marshall's book is one of 303 pages. It is well printed and quite well illustrated. There are no colored plates. The work is designed for the use of students and general practitioners. The descriptions are brief and concise. There is no departure from the ordinary construction evidenced in the work, except, perhaps, that the theory of color perception developed by Mr. Eldridge-Green is described and adopted over the theories of Young-Helmholtz and Hering. The concluding chapter is devoted to a description of the visual requirements for various public services in the United Kingdom. The work is well suited for those who wish to obtain only a brief authoritative view of the subject.

Prisms: Their Use and Equivalents. By James Thorington, A.M., M.D., Author of "Refraction and How to Refract," "The Ophthalmoscope and How to Use It," "Retinoscopy." Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine; Fellow of the College of Physicians of Philadelphia; Member of the American Ophthalmological Society; Ophthalmic Surgeon to the Presbyterian Hospital, etc. 118 illustrations, of which 18 are colored. Philadelphia: P. Blakiston's Son & Co., 1913.

Thorington's work on prisms is one that will be welcomed by ophthalmologists, as this is a subject that is covered too briefly in the average text-book on diseases of the eye, and one on which the practising ophthalmologist is seeking information. The volume is one of 144 pages, copiously illustrated by figures in the text and colored plates. Abstruse formulæ are avoided. The subject is treated as simply as possible consistent with a practical presentation. The work cannot but become popular with all who are engaged in the study of optics and ophthalmology.

# Society Reports.

## CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

*Held in Washington, May 6, 7, and 8, 1913.*

(Special Report to the MEDICAL RECORD.)

*Tuesday, May 6, 1913.*

THE PRESIDENT, DR. WILLIAM C. GORGAS, IN THE CHAIR.

**Study of Renal Function.**—Dr. HENRY A. CHRISTIAN of Boston read the first paper on this subject. He stated that renal function was of interest to the physician and the surgeon alike, since organic and pathological changes made it important to know how the kidneys were functioning concomitantly and singly, in order that they might know what form of remedial measures were appropriate; for upon this depended life and the question as to the advisability of a surgical risk. Observation had been made in the changes affecting the color, reaction, concentration, constituents, both qualitatively and quantitatively, in both normal and abnormal urine, with the object of correlating these findings with clinical conditions. The writer reviewed the work of a number of investigators as to the effect of various substances on renal function and discussed the selective action of certain of these substances for the glomeruli and of certain others for the tubules since such observations had promised to be useful in locating kidney lesions. He said that in the diagnosis of pathological lesions of the kidney function tests might be expected to yield information on two points: First, as to whether the kidneys were diseased, and, second, as to what type of pathological lesion they showed. A review of the methods of testing renal function by measuring the excretion of salts, water, lactose, potassium iodide, and sulphonephthalein, by measuring the retention of non-protein nitrogen in the blood, by the determination of diastase in the urine, by determining indican in the blood, or by estimating urinary acidity, showed that great aid had been given clinically as to whether the kidneys were diseased, but distinctly less help had come in answering the second question, as to what type of lesion the kidney showed. As in all forms of clinical diagnosis, not a single test, but many, yielded data on which diagnosis must be based. In this sense functional tests had yielded new data, and a discriminating valuation of these new data, along with a consideration of data furnished by other methods of examining patients already long in use, justified them in making a diagnosis of renal condition with increased certainty. They could expect fewer failures in renal diagnosis than before they had these functional tests, but so long as increased study failed to yield a demonstrable anatomical change to correspond with all observed functional variations, so long would they remain unable to make anatomical diagnoses which in most cases would prove to be correct when the pathologist examined the kidney.

**The Prognostic Value of Studies of Renal Function.**—Dr. L. G. ROWNTREE of Baltimore presented this paper. He stated that the clinical diagnosis being made, in any individual case before offering a prognosis, certain problems must be investigated: 1. What pathological condition is found to underlie the clinical picture? 2. Was the condition localized to the kidney or was any other system as the cardiovascular involved? 3. What was the functional capacity of the kidney? Was this temporary or permanent? 4. Was or was not the condition one amenable to treatment? All the tests had proved of value, but some much more so than others. Those of most importance in testing renal capacity were dye substances, especially the phthalein; among the tests of retention through the quantitative determination of the concentration of certain substances in the blood, cryoscopy, total incoagulable nitrogen, and urea were most important. The phthalein test was of value in all pathological conditions, whereas certain cases of severe nephritis, even in uremia, showed no marked increase in rest nitrogen or urea So the presence of cumulative phenomena was of the greatest significance where prognosis was concerned, while their absence was not. Functional studies revealed only the excretory capacity of the kidney, but did not make the diagnosis or settle the prognosis. They should be used routinely in conjunction with other procedures. Where the phthalein test revealed decreased renal capacity, one of the blood tests, urea, rest nitrogen, or cryoscopy should be employed to determine the presence or absence of cumulative phenomena. Dye substances other than phthalein need not to be employed prognostically, since they yielded less quantitative and less reliable results and added nothing to prognosis. The phthalein test was the one for general use under all conditions. Its findings could be verified and its indications strengthened by the employment of selected tests in different conditions. The iodide and salicylate tests were not of great prognostic value. Lactose was unreliable, since its total suppression occurred in moderate lesions of a given type, but suppression in chronic nephritis indicated a severe lesion. The urinary urea was of value only in relation to unilateral renal disease. Phloridzin had a tendency to exaggerate the degree of functional injury and hence it was not of great value. Salt in a marked tubular hyposthenuria carried much prognostic significance, otherwise the chlorides were of only slight prognostic value. If with the water test a very marked oliguria or anuria persisted it was of significance. Diastase might be tremendously depressed in moderate degrees of renal injury, while at other times it was not affected proportionately to the injury, hence it was not reliable for determining total capacity. In unilateral cases the diseased kidney was correctly indicated. The value of total coagulable nitrogen and of urea in the blood had been enhanced by the introduction of newer and more accurate methods by Folin and Marshall. These tests could be used interchangeably and had about the same value. Increased concentration of these substances did not always occur in severe renal involvement; hence their normal concentration in the blood did not indicate normal kidneys. Their increase signified renal injury and the extent of the increase was of extreme value in determining the extent of the injury. They were not of value in determining the diseased kidney where only one was involved. Cryoscopy occupied a similar position, with about the same significance. A study of the combination of these tests was needed in order to determine the extent of parallelism in their findings. With cholesteremia they had had no experience and with the Ambard constant not sufficient experience to justify an opinion.

**The Study of Renal Function; Its Bearing on Treatment.**—Dr. THEODORE C. JANEWAY presented this phase of the subject. He declared that in the domain of chronic diseases of obscure origin, diagnostic skill, inadequate though it might be, usually ran far ahead of remedial measures. In no disease was this more true than in the medical diseases of the kidney. From a broad standpoint the sulphonephthalein test and the less satisfactory ones which it had replaced had greatly contributed to the effectiveness of the treatment. The medical diseases of the kidney which were grouped under the comprehensive term nephritis did not permit of so easy an attack after recognition. The internal treatment of renal disease had made definite progress along two lines: (1) The study of experimental nephritis in animals had made clear the existence of isolated disturbances in the excretion of individual constituents of the urine, and the existence of definite types of abnormal reactions of the diseased kidney to stimuli. These had been found to have their counterparts in human nephritis. (2) The accurate study of the salt and water exchanges in human nephritis and their relation to edema, had resulted in a precise and scientific method of treatment which was highly effective in certain types of renal disease. Vascular hyposthenuria must be sharply differentiated from the hyposthenuria due to primary disturbance in the ability to secrete sodium chloride. This discrimination was of real importance in the management of clinical nephritis. Closely allied to this state of irritability of the vessels was their susceptibility to fatigue. This factor like the allied phenomenon of vascular over-irritability should never be overlooked in treatment. It justified the custom of giving caffeine diuretics intermittently, and in comparatively small doses. When a diuretic of this type was needed he used theocin. The initial dose of these drugs should always be small, because of the possibility of constriction resulting. The response of the kidney vessels to digitalis seemed to follow somewhat the same laws. Inasmuch as such a drug as digitalis would produce dilatation of the kidney and constriction of the remaining splanchnic vessels, it seemed not impossible that polyuria and hypertension were in their fundamental pathogenesis identical. In these vascular types of nephritis he urged restriction in the use of water and the common beverages. Water tests were most important guides to treatment, especially in the convalescent stage of acute nephritis. When testing for the excretion of water there should be absolute uniformity in the salt intake. Therapeutic means of combatting nitrogen retention were conspicuous by their absence, aside from enforcing a physiological economy of protein on general principles. The observation of the uncoagulable

nitrogen of the blood was of great importance prognostically, though it did not make the outlook any the less grave. In the same way the sulphonephthalein test could not serve in any way as a guide to treatment. In chronic passive congestion of the kidney, it might frequently afford a most useful measure of the degree of improvement in kidney function during treatment. The same considerations held good for Wohlgemuth's tests for diastase. The treatment of edema was much more satisfactory. The salt-poor diet remained the most effective measure in the treatment of edematous types of subacute and chronic nephritis. With the restoration of kidney function and the absorption of edema, they had observed the return to normal of greatly delayed potassium iodide excretion. The potassium iodide test gave an interesting side light upon kidney function and its restoration in these cases. What constituted normal elimination depended upon the test employed. He had been using the von Monakow test with starch paste and nitric acid which made forty-four hours the upper limit. The one essential guide to treatment, as Widal's studies had shown, was the absolute salt balance. It was immaterial practically, though highly important theoretically whether the cause of the salt retention was in the tissues or in the kidneys. Salt and water were retained and the edema was largely dependant upon this fact. The graphic record of daily salt intake and output, with the weight curve, permitted of exact knowledge concerning the degree of salt retention. The management of the salt intake in such cases of renal edema was altogether analogous to the management of the carbohydrate intake in mild diabetes. As long as edema persisted the salt of the diet should be kept at a minimum. After the absorption of the edema the ability to excrete added salt should be tested occasionally, and the increase in intake governed accordingly. By the exact estimation of sodium chloride tolerance and the adjustment of intake at a point below the ability of the kidney to excrete salt, chronic cases might be kept free from edema, over long periods of time, even where functional recovery was not complete. At the same time the management of the water balance demanded equal attention. This was of special importance in acute nephritis. Intelligent care was possible only with the use of graphic records of water and of salt intakes and outputs. The relation between intake and outputs in both substances was of more importance than absolute amounts. Not the least contribution which the study of renal function had made to the treatment of nephritis was its method of visualizing the actual response of the kidney to the therapeutic measures from day to day.

Dr. George Dock of St. Louis said he could add very little to Dr. Janeway's remarks, but he wished to call attention to the noteworthy fact that in the discussion of this interesting subject they had had statements from men who were actually doing the work and observing its results, both experimentally and clinically. While the examination of the urine was very old, they had until recently suffered from a tendency to rely on single diagnostic methods. For a long time they laid great stress upon the presence of albumin, or casts, or urea, neglecting the more complete and thorough examination of the patients, such as the blood-pressure, etc., the importance of which can scarcely be overestimated and which they can no longer afford to neglect. Immense practical gains had already been made from this careful study of the renal function, and still more could be looked for in the future, after more of these cases had come to autopsy. They needed not only a great deal more knowledge regarding kidney function, but also regarding kidney pathology. After they had applied the methods that had been described, and no doubt others that would be discovered, to the kidney functions during life, then more complete anatomical investigations should give us an exact knowledge for prognostic and diagnostic purposes.

Dr. Hugh Cabot of Boston said that many surgeons had neglected this question of kidney function, assuming that the study of the urine would give them sufficient data. It had already been pointed out, however, that the routine examination of the urine would not give to the surgeon information upon which he should feel justified to act, although many still held the assumption that it would. The speaker said he wished to discuss the value of these studies of the renal function in enabling one to tell beforehand the probable safety of any operation. In his work he had come to rely upon comparatively few. None of the color tests seemed to him to possess the value of the sulphonephthalein test of Rowntree and Geraghty. He had employed this in a large number of cases and had come to esteem it very highly. The other test he had found valuable was the one of the nitrogen retention, which had recently been placed within the reach of the average clinician. These two tests, properly carried out, gave one a very accurate idea of the prognosis.

**Address of the President.**—Dr. William C. Gorgas delivered an address, illustrated by lantern slides, on "Sanitation at Panama in Its Relation to Sanitation in the Tropics Generally." In Panama, in 1904, when the United States began the construction of the Panama Canal this was universally looked upon as being one of the most unhealthy spots in all the tropical world; that this reputation was not undeserved but was warranted by the facts in the case; that the sanitary measures put into effect by the United States had enabled constructors of the Canal to proceed for the past nine years with no greater loss from death than would have occurred if the same work were being carried forward in most parts of the temperate zone; that this work had been accomplished at no very great expense; that, therefore, similar results could be obtained either by communities or individuals in any part of the tropics, was his argument. Mr. Roosevelt, who was in the Presidential chair at that time, was thoroughly familiar with the work in Cuba, and believed that the mosquito theory had been demonstrated beyond peradventure. Yellow fever began steadily to decline. In November, 1905, they had their last case of yellow fever in the City of Panama, and in May, 1906, their last case in Colon. During 1906 the Sanitary Department was raised to its maximum efficiency and in May, 1907, the sanitary work had been as follows: 1906, 39.51; 1907, 24.50; 1908, 8.68; 1909, 7.55; 1910, 7.50; 1911, 7.65; 1912, 6.37. These figures demonstrated that by 1908 they had a force of 38,000 employees on the Isthmus who were working in the sun, rain, and weather at the hardest kind of labor, with a death rate from disease of 8.68, not any greater than the same men doing the same work would have had in the United States. It was interesting to speculate upon what would have taken place if the President and Secretary of War had acted in accordance with the recommendations of the Executive Committee and decapitated the men in charge. The methods used were based upon the belief that yellow fever was a disease due to filth. By December, 1906, they had 9,000 non-immune connected with the commission, of whom 6,000 were Americans. It was probable that half of these would have died of yellow fever had sanitation remained as it was in 1905. This would probably have involved a suspension of the work till conditions could have been corrected, thereby causing a delay in the completion of the canal of at least two years, and very probably public opinion would not have supported a project that involved such loss of life and the work would have been delayed indefinitely. The actual expense of the measures that had accomplished these results had not been large, about $365,000 per year, or about one cent per day per capita. The expense of sanitation in the Isthmus was frequently spoken of as being large. This came about from the fact that official reports gave the expense of the Sanitary Department as having averaged $1,600,000 a year. And very naturally in reading this report one assumed that the expense of sanitation and the expense of the Sanitation Department were synonymous, but not more than one-fifth of the expense of the Sanitary Department was involved directly in the measures that had resulted in the eradication of yellow fever and the control of malaria. More than half the expense of the department was involved in the care of the 1,800 sick that they had constantly on hand. It was quite evident that if people could be protected against tropical conditions at Panama, the same thing could be accomplished in any other part of the tropics. The results at Panama were so in the limelight that they were attracting attention from all parts of the tropics.

## MEDICAL SOCIETY OF THE STATE OF NEW YORK.

(Special Report to the Medical Record.)

(*Continued from page 872.*)

SECTION ON PEDIATRICS.

*Wednesday, April 30.*

**A Case for Diagnosis.**—Dr. George T. Imrie of Rochester presented this case and asked for opinions regarding the diagnosis. The patient was a baby, nine months of age. She was the sixth child of healthy parents and at birth was normal in appearance and weighed 8¾ pounds. She had been unable from the time of her birth to hold up her head as a normal child did. She had had attacks of cyanosis, an enlarged abdomen, and bulging over the sternum. There was also a heart leakage.

Dr. Charles Herrman of New York said that he considered the data characteristic of Mongolian idiocy with congenital heart lesion. The case recalled one that he had been a short time ago in which the temperature went to 109.4° F. The child died and no autopsy could be obtained. There must have been a defect in the regulating center.

Dr. George Van Gaasbeck of Kingston said that about 50 per cent. of these cases had congenital heart trouble and easily succumbed to tuberculosis or pneumonia.

Dr. Thomas S. Southworth of New York said that the prognosis in this case was very bad because of the early inability to hold the head. The child's head measured only 15⅝ inches in circumference and it seemed probable that if the child survived she would be microcephalic. She would probably belong to the low grade type of Mongolians. The history and poor development of the child did not hold out any definite hope that she would make much progress.

**The Use and Abuse of Sugar in the Diet of Children.**—Dr. Elias H. Bartley of Brooklyn presented this paper. He said that although sugars were among the most valuable articles of human diet, yielding their heat and energy on the least energy of the organs of digestion and assimilation, yet this very characteristic made them harmful if taken in large quantities. Twenty years ago he had called attention to the clinical evidence of the harmful and far reaching effects of the excessive use of sugar upon the digestive organs, the mucous membrane, and the general health of growing children. The many years of observation since that time had only served to strengthen the convictions expressed at that time. The injurious effects to which he referred were, irritation of the gastric mucosa, gastric catarrh, interference with the digestion and absorption of fats and proteins, the production of excessive fermentation with the formation of irritating organic acids, attacks of so-called "bilious vomiting," acid intoxication, anemia, and general malnutrition. He attributed these results chiefly to the fermentative changes, especially of the hexoses as invert sugar, and of glucose taken as such. He now believed that sugars when taken into the empty stomach acted as direct irritants of themselves and that they rapidly generated irritant organic acids. Sugar incapacity soon developed in certain older children as well as in infants. Invert sugar and glucose were more injurious than cane malt or milk sugar. Cane sugar was partially inverted or converted into glucose and levulose by heating with organic acids. The fruit jellies, jams, etc., contained sugar that was partially inverted. Modern confectionery contained from 10 to 25 per cent. of glucose or corn sugar, made from starch by boiling with sulphuric acid. The early symptoms from sugar eating might begin a half hour after eating and seemed to be due to the local disturbance and not to a disturbed metabolism. There were six ways in which excessive sugar ingestion could be harmful: (1) by direct local irritation of the gastric mucous membrane; (2) by the production of excess of acids; (3) by interfering with the digestion and absorption of fats, because of the excess of solids in the bowel and consequent malnutrition and anemia; (4) the disturbance of carbohydrate metabolism; (5) the production of a condition of a form of acid intoxication, differing however from the better known acidosis of diabetes, cyclic vomiting, etc.; (6) by the remote effects in the nervous system and on the mucous membranes. The attention of the public should be called to the harmful effects of the excessive use in sweets in such a way as to check it.

Dr. Phillip S. Potter of Syracuse said that one writer had recently made the statement that the child should be given all the candy it wanted as this was a cry of Nature. Such a statement was pernicious. Urticaria, rheumatism, and respiratory affections in children might result from the ingestion of too much sugar. Dr. Potter reported several cases of children coming under his care who showed all the symptoms of tuberculosis but with no physical signs of that disease, neither did they respond to the von Pirquet test. After cutting down the sugar in the diet of these children they recovered. He cited another case in which extraordinary nervousness, bilious attacks, headaches, and malaise were cured by cutting down sugar. There were children who could digest and care for from 4 to 8 ounces of sugar a day while there were others who could not stand it.

Dr. Charles Herrman of New York said they were indebted to Dr. Bartley for his paper. Children showed a very variable degree of tolerance to sugar. Those cases that showed the symptoms of tuberculosis were the ones known as "susceptible," and they easily fell a prey to that affection.

Dr. George N. Jack of Buffalo said these cases that were known to be susceptible to tuberculosis were hypersensitive and had a high leucocytosis. A large amount of sugar increased the leucocytosis. The waste products of the blood were dumped along the bronchi, larynx, and follicular glands and later the changes here spread along the trachea and bronchi and set up an asthmatic attack.

Dr. William B. Hanbidge of Ogdensburg cited an instance where in a children's home an ignorant nurse fed the babies on sugar and water whenever they cried and a great deterioration in their health resulted. He knew of two children who were raised without any sugar and they were fine healthy children.

Dr. Elias H. Bartley of Brooklyn said that in regard to the children who did well although the mother's milk contained a high percentage of sugar, they should remember that all children would not have done so well as children reacted very differently to large amounts of sugar.

**Some Observations on Infant Feeding.**—Dr. Harry Rulison of Albany presented this paper. He stated that the normal healthy child had a tolerance for a wide variety of foods. In the feeding of the normal healthy child complicated formulæ and complex methods were not necessary. What was necessary was a knowledge of the nutritioual requirements of the child to be fed and a correct interpretation of the various signs of nutritional disturbance, together with the ability to refer them to the particular element in the food that was causing the disturbance. The failure to make a correct interpretation was the cause of most failures in infant feeding. The food should have sufficient caloric value to meet the needs of the child and should be well balanced in respect to its various constitutents. It need not approximate breast milk nor even resemble it. Both the percentage and the caloric methods had their value but should not permit either to hamper him in the treatment of the individual case. The problem as to whether it was better to feed by age or by weight was still with them. He was in favor of larger quantities at longer intervals. One feeding in four hours was frequent enough. There should be plenty of water between feedings. The early elimination of night feeding was desirable but not always possible. It was now the consensus of opinion that the proteins gave little trouble, even if they formed 8 or 10 per cent. of the total amount of food. He usually began by feeding from 1½ to 2 per cent. protein and increased the quantity to 3 or 4 per cent. by the end of the first year. Protein resulted in no harm provided a certain amount of whey salts were present. He took issue with Cowie and Lyon on the statement that little or no protein was split up in the stomach on account of the normal absence of hydrochloric acid. He had found that the protein in the stomach was completely dissolved during incubation when no hydrochloric acid was present. It had been discovered that the fats were split up by the pancreatic lipase to a greater extent than was formerly believed. While fat would seem easy of digestion theoretically it was a different thing in practice. There were many children who could not metabolize even a small quantity. The average requirement was 2 per cent. or less. Of the carbohydrates maltose was the most easily digested and assimilated and the least liable to fermentation, but it had not given him any better results than cane sugar. The use of lactose was based on theoretical considerations rather than on direct results. Starch digestion in infancy was not as difficult as was formerly believed. Many edemas were supposed to be dependent upon sodium chloride; some occurred without renal or cardiac lesions and were dependent upon faulty metabolism; these a salt free diet would sometimes clear up over night. Proprietary foods had their place but should not be used "hit or miss." The directions accompanying them should be disregarded. Whey feeding should be condemned in dyspepsia, intestinal intoxication, atrophy, and spasmophilia. The administration of lime water was to be avoided as a routine measure as it delayed digestion.

**Infant Feeding with Undiluted Cow's Milk.**—Dr. William B. Hanbidge of Ogdensburg read this paper. He said that twenty years ago his attention had been called to the advantages of whole milk by a sister who had charge of a number of babies in an institution. In November, 1912, he had reported a series of 39 cases collected from various sources, in 35 of which the results had been very satisfactory. He now had a more recent series of 50 cases, 15 of which were from his own practice. Of ten of these children who were healthy there was one that could not take whole milk. Dr. Hanbidge related a number of cases sent to him by other physicians in which the babies were fed successfully with whole milk after other methods had failed. He believed that children on a concentrated food like whole milk should be fed only when hungry. If they

slept and got a little behind in their nourishment, they could easily make it up. It was nature's way to feed both children and young animals only when they were hungry. In feeding experiments the important thing was to arrive at the truth irrespective of theory. It was possible that in trying to obtain a food that chemically resembled mother's milk they had been led astray. The process of digestion was too complicated for chemistry to be the final judge. They had learned that the stomach did not hold the dominant place in the processes of digestion that they formerly had thought it did. The muscles of the new-born babe were poorly developed and it was possible that in giving a highly diluted food dilatation and atrophy were caused which interfered with the proper emptying of the stomach. Possibly they were diluting the gastric juice so that the process of digestion was retarded. Might not the distention and muscle weakness in the bowels result in colic? Experiments had convinced him that from 1½ to 2 ounces or possibly 2¼ ounces of whole milk for each pound of body weight provided sufficient nourishment for twenty-four hours. A popular work on pediatrics considered 32 ounces about the proper amount of modified milk for an infant eight weeks of age; the same child on whole milk would require only from one-half to two-thirds that amount.

**A Practical Study of Goat's Milk in Infant Feeding as Compared with Cow's Milk.**—Dr. DeWitt H. Sherman and Dr. Harry R. Lohnes of Buffalo presented this communication. Dr. Sherman said their object was to learn if possible, the reason why goat's milk agreed better with some infants than cow's milk. The babies were selected at random from the inmates of St. Mary's Infant Asylum and Maternity Hospital of Buffalo. The goat's milk used averaged from 1½ to 2 per cent. richer in fats than the cow's milk used in the institution. A series of experiments in which test meals were given and withdrawn one hour from the middle of the feeding showed that the digestion of the cow's milk was slower. The curds of the goat's milk were smaller and more flocculent, corresponding to the appearance in test tube digestion. Dr. Sherman presented a table showing the greater stimulating effect on the stomach of goat's milk over that of cow's milk, and the greater stimulating effect of both as compared with proprietary foods prepared without milk, and finally the greater stimulating effect of all three as compared with barley water. So far as absorption and gain in weight were concerned their statistics were indefinite because the babies being institution babies were apt to gain slowly, owing to an epidemic of streptococcus infection which had swept through the infants' ward at the time these experiments were in progress, and because a certain number who were doing well were removed from the institution before the experiments were finished. There were 16 cases tested, on similar formulæ. Of these 12 gained more rapidly on cow's milk and four on goat's milk. The gain in the former group was in the ratio of three to one and in the latter group in the ratio of nine to one. The more thorough emulsification of the fat in goat's milk prevented the separation of cream upon standing as occurred in cow's milk. This fact might be an element in reducing the tendency to regurgitation in goat's milk as compared with cow's milk, and further might be a very important factor in lessening the liability to sour vomiting due to fatty acid fermentation, so common in high fat mixtures. On account of the small size of the fat globules, there was probably present in the goat's milk a smaller amount of the lower or volatile acids. The babies as a whole tolerated equally well similar amounts of goat's or cow's milk with the same diluents, but as the goat's milk contained higher fat percentage than the cow's milk, the children actually received more fat per feeding and hence a higher caloric value. It was consequently strange that more babies gained on cow's milk than on goat's milk modification. The stools of the infants on goat's milk were smaller and of a more vivid yellow color. The age did not influence materially the ratio of gain on goat's milk versus cow's milk, but the younger the baby the more evidence pointed toward a greater gain on goat's milk. The only conclusions that could be drawn were that in the child whose resistance was below par, goat's milk agreed better because it was less stimulating, because it contained fewer volatile acids, and because of its more flocculent curds which made it more easy of absorption by some children.

**Infant Feeding from a New Standpoint.**—Dr. Godfrey R. Pisek of New York presented this paper. He said that the history of infant feeding embraced many methods which had succeeded one another in popularity. They had had raw milk, pasteurized milk, whole milk, the percentage method, the caloric method, etc. They pasteurized the milk to eliminate bacteria and then added millions of bacteria in order to aid digestion. When one method was in vogue and every one followed that the situation was not so difficult, but when all of these methods were the fashion at one time matters became very complicated. Specialists denounced proprietary foods and then prescribed those same foods to their patients. A case had recently been reported to the writer of a physician who had the care of an infant whose nutrition was not progressing properly. The mother wanted to feed the infant condensed milk but the attending physician objected and adduced evidence for his stand from a textbook. The mother asked a consultation with the author of the textbook and that authority, much to the chagrin of the attending physician, prescribed condensed milk. What wonder was it with pediatricians preaching one thing and practising another that the laymen were bewildered and the general practitioner was in a hopeless predicament. Scientific feeding of infants was bound to fall into disrepute unless pediatricians restored harmony in their own ranks. Unless they got together and agreed upon fundamentals they must not be surprised to see the manufacturers of proprietary foods flood the market with literature which would carry weight with the lay public in the absence of any authority upon which they could rely. Students went from one clinic to another and heard their teachers make contradictory statements and the question arose "How was the general practitioner to know what to do when authorities flatly contradicted one another in what were supposed to be the fundamentals of infant feeding?" Scientific infant feeding consisted in doing what was right at the time for the particular infant. It was impossible to state in a book what was to be done under all conditions. Each procedure had its place and in that place was scientific feeding; out of its place it was unscientific. A statement made years ago might have been correct at that time and yet be incorrect to-day. The average student in an agricultural college or domestic science school had a better knowledge of the fundamentals of nutrition than the average medical practitioner. Fundamentals of physics, chemistry, bacteriology, and surgery were uniformly taught. In infant feeding it was different. Infant feeding must be approached from a new standpoint and they would do this when they concentrated their teaching on the broad general principles of the science of nutrition of which infant feeding was only a branch.

Dr. Charles R. Witherspoon of Rochester said that it took a man who practiced general medicine just long enough to have two babies under his care to learn that he could not feed all babies in the same way. In feeding an infant one should have a good reason for what he did. It was important to know the number of calories that one was giving but one should not depend entirely upon that; one should know the percentage of the different constituents in the food, but one should also know more. He should know about stools as a macroscopical examination of the feces would teach him much; he should know what a healthy baby looked like and what he felt like.

Dr. J. Roberts Johnson of Syracuse said that it must have occurred to some of them while listening to the papers that they were still far from having definite and settled convictions. Unless they did agree on fundamentals they would be the laughing stock of the layman. They should have a knowledge of the general requirements of the infant and then study the individual case. Proprietary foods had their place but should be under the control of the physician. In his experience he had had the greatest trouble with the excess of fat. The malt sugar was easier cared for by the economy than any other type of sugar. The use of goat's milk was not as practical as other methods because it could not be obtained in all localities.

Dr. George Van Gaasbeck of Kingston related an instance of one mother who had reared nine children feeding them at irregular intervals and all very healthy robust children.

Dr. L. A. La Fetra of New York said that the subject of infant feeding was of the utmost importance to them as it was the distinguishing mark of the pediatrician. At present there was confusion as to what method should be used in a particular case. The truth was that infant feeding was easy only on paper. Babies had thrived on every imaginable manner of feeding but this proved nothing except that the healthy baby was very resistant. The cases that were interesting to them were the cases of difficult feeding; from these they could learn something. In these difficult cases one must endeavor to select that particular form of food that would suit that individual baby. If the method chosen did not succeed, one should find out the cause of failure if possible. The papers on this subject had been exceptionally good. Dr. Rulison had spoken of the caloric method versus the percentage method; this was a mistake. There was no antagonism between the methods. Both were valuable and the two should be combined. Even if a

baby was not being fed in the way one thought it should be fed, if it was doing well it should be let alone. Individual babies differed in their capacities for sugars. One had to find out which sugar was suitable in each case. As to the salts, it seemed to him that they did not know much about them. The cases cited were exceptional cases. According to theory the edematous, water logged baby ought to have no salts; yet they gave them skimmed milk and the edema disappeared. How about the theory? As to whole milk feeding, one might take a baby that was vomiting an ordinary quantity of mother's milk, put it on concentrated food, giving it sufficient number of calories and the baby would do well. One badly nourished baby was cited as taking double the quantity of food supposed to be required, but the fact that the baby was badly nourished showed that it needed the excess. Having sufficient calories, sufficient liquid and a proper balance of the food elements, one was on the right road to the correct food. The statement that proprietary foods had no food value was not true. These preparations had a food value and could be made good use of. In their infant feeding at Bellevue Hospital they used a wide diversity of foods, top milk, skimmed milk, whey, *Eiweissmilch*, condensed milk, dried milk, and all forms of sugar and there was a place for each.

Dr. George Dow Scott of New York said that he had used the percentage method when that was the correct thing and had tried to use the caloric method, but he had given them up. It seemed to him that on the theory of the caloric method one might argue that cabbage had calories and therefore one might feed cabbage. One had to get down to the fundamentals, facts of proteins, carbohydrates, and fats. He emphasized the fact that fruit juices were absolutely essential for the normal child, either raw orange or pineapple juice, or the juice of stewed apples, pears, or prunes. In the feeding of infants, they needed the theory but should not lose sight of common sense.

Dr. T. Wood Clarke of Utica said that Dr. Sherman had done good work and that if more men had the patience to carry out work of this kind they would get results that would teach them something. Hydrochloric acid had a great deal to do with the formation of the curd. They must have curds but they did not want tough curds. Lime water, instead of decreasing the hydrochloric acid, increased it and was absolutely contraindicated. Sodium citrate acted entirely differently. It lowered the total acidity slightly and greatly increased the acid salts; there was no free hydrochloric acid, and only a little in combination, and no hard curd. Sodium chloride and citric acid were formed which were not so active in forming the curd. His advice was, therefore, to citrate the milk. A good test meal was of value. They should study the chemistry of the infant's stomach; this was a matter that was being grossly neglected.

Dr. Harry Rulison of Albany said that, in relation to the fermentation of lactose and maltose, he did not mean lactose was more fermentable than maltose, but lactose seemed to be more influential in producing diarrhea. He had stated his disapproval of lime water as a routine measure. Lime water had been used in the effort to make cow's milk like human milk and it was supposed that human milk was alkaline, but it was not always so. Again lime water had been supposed to facilitate casein digestion and to prevent curding. Curding was a natural process and should not be prevented. Again, lime water was used for its effect on acidity. This resulted in delaying the passage of the stomach contents and was not a desirable effect.

Dr. William B. Hanbidge of Ogdensburg said he had been conservative in his attitude toward whole milk feeding. One of the greatest mistakes in infant feeding was that of giving too much water. So long as the baby was thriving it was better to leave it alone. A good plan was to experiment first and to theorize afterward.

Dr. De Will H. Sherman of Buffalo said that in dealing with an irritable stomach one should bear in mind the foods that would be stimulating and those that would not have such an effect.

Dr. Godfrey R. Pisek of New York said that Dr. Rulison showed the tendency of the German school but that he would be more successful if he would take what was good from that school and apply it in connection with other methods. In regard to the long intervals between feedings, it should be remembered that the child's stomach had a tendency to empty itself rapidly. It might empty itself entirely in thirty-five minutes, and the child would often be ready to take more food. He had seen such instances.

Dr. Charles R. Witherspoon of Rochester spoke of the difficulties that confronted the general practitioner when it came to the subject of infant feeding. When the pediatrician was called in the family had confidence in him and were willing to wait for results, but often this was not the case with the general practitioner, and the only thing for him to do was to endeavor to win the same confidence that was bestowed on the specialist by informing himself more thoroughly on the subject of infant feeding.

Dr. Harry Rulison of Albany, in reply to the question as to what kind of test meals had been employed, said that they had used a great variety, matzoon, farina, with bismuth, and all kinds of liquid foods.

*Wednesday Afternoon, April 30.*

**Election of Officers.**—*Chairman*, Dr. Thomas S. Southworth of New York; *Secretary*, Dr. Joseph R. Roby of Rochester.

**The Physician and the Mentally Defective Child.**—Dr. Isabelle T. Smart of New York presented this paper. She declared that the problem of the defective child was demanding the earnest consideration of the State legislators, sociologists, and educators, but that up to a very recent time the physician had been content to allow the layman to enter this field of pediatrics and to control practically all that had been or was being done for this type of children. It was contended that physicians did not know how to diagnose these cases. This was a grave accusation and reflected uncomfortably on the acumen of medical men and women. Dr. Smart considered more particularly the borderline cases that were more or less of a puzzle. These were the children that the general practitioner was apt to pass over lightly, telling the family to wait until the child was seven, or fourteen, or twenty-one years of age. A strong plea must be entered for the careful and painstaking examination and study of every unusual child presented to any physician. Too often these children received no attention unless they were suitable for institutional care. The outcome in many of these borderline cases depended upon proper nourishment and correction of physical defects, as a large number of these cases of mental abnormality were dependent upon physical defects. Several investigators from the Vineland Laboratory of Psychical Research had obtained permission to examine immigrants at Ellis Island. Of 44 cases tested, 33 were selected by the medical inspector as probably mentally deficient. Of these 33, 15 proved to be mentally defective, while 18 were normal. Less than one-half had been correctly selected by the medical inspector, while seven-eighths were correctly chosen by the experts. There should be a thorough exhaustive examination by a scientifically trained physician in all these cases, by one who could get at causes and pathological conditions as well as the defects themselves. It was time for all physicians whose work was primarily with children to be up and doing so as to be able to meet the snap diagnoses of the untrained or partially trained so-called expert. Instead of lightly passing over the backward child he should be watched during all of his formative years; nervous manifestations should be noted; school progress and mental acumen measured; eyes, ears, throat secretions, heart, lungs, liver, all should come in for a share of attention. Special attention should be directed to hypersecretion and undersecretion, particularly with reference to the pituitary gland about which they know so little. The physician could not afford to be behind the times in this matter, but must keep abreast of the big social problems. It behooved them to make themselves wiser so that they could make an intelligent protest against laws that endangered the defective class and also normal children, for the normal child might later marry the unfit and so widen *ad infinitum* the vicious circle. It could be shown that it would be economy in the long run to provide State supervision for defective children.

Dr. Mary Sutton Macy of New York said that Dr. Smart had called attention to the child showing retarded development from infancy, but she had not emphasized it sufficiently. The consequences of retarded development, or of even a temporary arrest of development in some slight particular, were too little appreciated by physicians as a whole, whether they were specialists or general practitioners. Dr. Macy said that she had been impressed by the lack of data on the normal development of the child after the age of three years and especially so with the apparent tendency to neglect all differentiation between the digress of development of functions and organs in the child after six years of age and in the adult. If they were ignorant on these points as to the normal child, they could not expect to advance much with the abnormal, the retarded, or the arrested forms of development which appeared in the mentally defective. Dr. Macy said that she and Dr. Smart had collected data in the course of a routine examination of 6,246 school children in the public elementary schools of New York City. All the cases were sent up on the presumption that they were mentally deficient. The children were picked out by the pedagogical

authorities because of their inability to advance in the grades without repeating each term; some for nothing more than a reputation for "excessive badness," or for chronic truancy; but some gave physical and mental evidence of low grade imbecility or idiocy which was unmistakable to the least informed layman. Of all these cases, 13 cases were truly institutional cases of mongolianism, imbecility, or idiocy; 51.8 per cent. were found to be in need of some very specialized form of pedagogical training. The large percentage of sensorial defects, as well as of general nutritional and neurotic disorders, might have had some relation to the degree of mental inadequacy, since the proportions in all these conditions were so universally larger among those requiring the special training of the ungraded classes. Of those examined, 88.6 per cent. showed eye defects; 67.7 per cent. ear diseases; 70.3 per cent. defective teeth; 33.2 per cent. enlarged tonsils; 32.3 per cent. enlarged adenoids; 46 per cent. both tonsils and adenoids enlarged; 53.2 per cent. speech defects; 6.4 per cent. epilepsy; 5.8 per cent. chorea; 37.3 per cent. other neuroses; 8.2 per cent. were tuberculosis suspects; 17.5 per cent. showed cardiac weakness; 68.7 per cent. showed nutritional disorders. Dr. Macy also gave statistics from 10,000 cases showing relative physical defects which she had presented at the International Congress on Hygiene and Demography. These statistics gave some idea of the immensity of the problem with which they had to cope. In another series of 125 cases, which upon the first examination gave evidence of greater or less degree of mental deficiency, without exception, following upon proper medical and hygienic care and the correction of physical defects, and having the advantage of specialized pedagogical attention during periods of from two to four years, had so far recovered from their feeble-mindedness that they had been able to resume and maintain their places in classes of children of their own ages.

Dr. Godfrey R. Pisek of New York said that Dr. Smart had not overdrawn her statements. In the New York schools and clinics these cases presented themselves in large numbers, and they certainly made an appeal to one's sympathies. Some change was bound to be made within a few years which would put this class of children into the proper hands. There were not enough medical men who were fitted to handle them at present. The study and recognition of these cases really made a specialty within a specialty. There were in New York City children with well-marked cretinism, eleven and twelve years of age, who had never received any treatment. There was one group of defective children which was sent by the schools for examination and classification. Even if these cases were recognized, how were they going to help them. A fully equipped department with a hospital in connection with it was needed where there would be corrective appliances, a room for physical therapy, facilities for the treatment of eye and ear defects, etc. When the general practitioner got these cases he usually sent them for adenoid or tonsil operations, and, of course, they were little benefited. Simple but effective measures were needed to put these children in their proper places in the world. The matter of Letchworth Village was an economic question. If the State could be made to understand the drain that such a defective child was upon the family income and the time of the mother, and what a burden to society it became later, legislators might see that it was economy for the State to care for and train these children. The lack of data regarding the child after the age of three years was accounted for by the fact that the physician did not see him so often at that age and he had not yet come under the control of the school. Possibly the prize baby contests that were being held all over the country might bring this type of children to the attention of the physician. These contests at least offered a field for the pediatrician to get into touch with a large number of children.

Dr. Ira S. Wile of New York said that Dr. Smart had been exceedingly conservative. It was said that there were 3,000,000 defective children in the United States; that four per cent. of the school children of the country were defective to the extent of requiring institutional care. There were in the State of New York 12,300 children who should have institutional care. There was at present a bill before the Legislature asking for the appointment of a commission to examine all the children coming into the children's courts in order to ascertain to what extent this class of individuals were defective and with the object of providing proper custodial care for them. It was said that physicians knew but little about these cases, and it was far from his purpose to contradict that statement. The school teacher was interested in advancing the pupils and had opportunities for making comparisons that the physicians did not have. Often the condition of the borderline cases was due to conditions at home; sometimes it was due to insufficient nourishment; or it might be due to eye or speech defects. Again, it was not easy to recognize these borderline cases and the older practitioners had not had the opportunity of studying the problem. The Vineland Laboratory was creating a false impression and leading people to think that every one was defective simply because they could not all do a certain thing as well as some one else.

**Social Pediatrics.**—Dr. Ira S. Wile of New York read this paper, in which he called attention to the weak spots in the present method of teaching pediatrics. He stated that the purpose of the medical school was to supply the community with men who were trained in caring for the public health. If they failed to teach their students the methods of preserving health and life they fell short of their ideal purpose. The position of the physician had altered in the community in that he was no longer regarded merely as an individual capable of curing individual cases of disease, but as a specially gifted man, capable of guiding the public in matters pertaining to health. The problems of infancy and childhood should not be given a subordinate place in the category of medical problems. When one considered that one out of every five in the population was a child whose welfare might be considered as belonging to the department of the pediatrician, that practically one out of every three deaths within the registration area fell upon a child under fourteen years of age, and that practically one-fourth of the total mortality in the registration area occurred under the age of 2.68 years, the immense importance of the field of pediatrics was accentuated. Recognizing the social and economic forces which interfered with medical progress, it was important to train the medical student so that he would appreciate the difficulties with which he would have to contend. It was impossible to give a complete course in sociology to the medical student with the present distribution of time, but a physician with a knowledge of sociology was far better prepared to cope with social problems in the manner that the future generations would demand. Physicians were urging more careful instruction in hygiene in the elementary schools, and yet the practical social aspects of hygiene were neglected in the great majority of medical colleges in the United States. The teaching of pediatrics must be strengthened. Medical colleges should have specially trained teachers for this subject. The value of midwives, the importance of health registration, the value of milk depots, and infant consultations were certainly pediatric themes. The relation of day nurseries, boarding-out and convalescent homes, and babies' hospitals were intimately bound up in the mortality rate. The value of school nurses, medical inspectors, school clinics, child labor laws, and district nursing were not foreign material in a broad-visioned course in pediatrics. The necessity of open air schools, the problem of the prevention of blindness, the detection and care of defectives formed topics in social pediatrics which were at present holding the attention of welfare workers, while the physicians were not fully acquainted with their relation to pediatric medicine. Students were not made to appreciate the full social and hygienic value of breast milk. The fundamental causes of infant mortality were poverty and ignorance. The physician might not be able to relieve the poverty, but he could correct the ignorance and discipline its stepchild, neglect. Pediatric medicine should be taught in relation to community life. This was the only way in which the preventive phases could be presented to the student in their true relative importance. To adequately teach the conservation and protection of infancy and childhood, medical schools must be socialized in spirit. If pediatrists were to be leaders in the preventive medical work that was the present ideal of medicine, the pediatric teachers must be aroused to their responsibility.

**Certain Neglected Aspects of the Problem of Infant Mortality.**—Dr. Philip Van Ingen of New York said that efforts toward the reduction of infant mortality had been chiefly directed toward deaths due to diarrheal diseases, which constituted from 20 to 30 per cent. of the total mortality during the first year of life. The very marked reduction in the death rate among babies in the Borough of Manhattan, New York, had been chiefly among this group of cases. From 25 to 40 per cent. of the deaths under one year were due to congenital debility, prematurity, etc. The figures for these deaths had not changed to any extent during the past seven years. An analysis of the deaths under one week and under one month showed a practically constant infant mortality rate for the group under one week, and a very small reduction in the rate for under one month, while from one month to one year, the reduction in 1911 was nearly 14 per cent., and in 1912 over

21 per cent., from the average for 1906-10. The problem presented by this portion of infant mortality was an all-the-year-round one, as the figures showed that a greater proportion of the deaths occurred during the winter months than during the hot months, although the variation was very slight as compared with from one month to one year. The New York Milk Committee had conducted a campaign of prenatal instruction and hygiene among the tenement mothers in the worst districts of Manhattan. It was a campaign of prevention through instruction during pregnancy, carried on by visiting nurses in the homes. The results of the first 1,375 cases show two deaths among the mothers, one from toxemia of pregnancy, one from acute hemorrhage due to placenta prævia; 95.3 per cent. gave birth to living babies at term; 1.2 per cent. to premature living babies; and 3.5 per cent. to stillborn babies. Of the babies born alive 97.3 per cent. were alive at the end of one month. In the Borough of Manhattan, as a whole, the death rate under one month per thousand births during the same period was 40.2 per cent. as against 27.5 per cent. for the supervised cases. The still birth rate was 34.3 per cent. as against 47.9 per cent. for the Borough as a whole. At the end of the first month 92.2 per cent. of the babies were being nursed entirely, 4.1 per cent. partially, and only 3.7 per cent. were being artificially fed entirely.

Dr. L. E. La Fetra said that those working on these problems had concluded that they were largely due to three factors: 1. The family income which involved the efficiency of the house. The schools should train the boy to greater efficiency. 2. The girls must be trained in home-making and child hygiene. The large majority of girls were likely to marry and should be trained for their work. 3. They had also the problem of eugenics and all that it implied. Instruction in the medical schools should be broadened out, but the problem was how to do this. Dr. La Fetra suggested a few lectures on sociological problems for students and so arranging the work of students in the out-patient departments that they would be brought in contact with the homes of the people and become acquainted with actual conditions. At Bellevue Hospital they had a chart for taking the social condition of the family of the patient down to the minutest details. As to the prenatal care of the mothers, there was no doubt but that such instruction in hygiene and eugenics would lower the infant mortality.

Dr. Godfrey R. Pisek of New York said that if the physician could be trained in the broad way suggested he would be prepared to displace those now in charge of institutions for children who had no interests in the children in the broad sense. If the physician was thus trained he would indeed be a doctor of public health. A part of the work of the doctor of health should be taken up by the pediatrist. It was often said that the smaller cities did not have these social problems, but there were few cities of 30,000 inhabitants that did not have their slums, and often they were worse than those in New York, and less was being done to ameliorate their condition.

Dr. George Dow Scott of New York said that those who were doing this work appreciated the fact that much must be done for the mother. The entire country should be districted and all mothers should be instructed in social hygiene; this was especially true of the foreign mothers. These foreign mothers did not know how to look after their children properly; they had been transplanted into a new environment and must be taught how to adapt themselves to their new surroundings.

Dr. Joseph Roby of Rochester said he wished to sound a conservative note. It had been found in an investigation in Chicago that the death rate was higher when there were four or more children in a family than where there were less than four. The problem of problems was over population and the millennium would never come without giving it due consideration.

(*To be concluded.*)

## PRACTITIONERS' SOCIETY OF NEW YORK.

*Two Hundred and Fifty-fourth Regular Meeting, Held April 4, 1913.*

The President, Dr. Brannan, in the Chair.

**Congenital Fusion of the First, Second and Third Dorsal Vertebræ and Ribs.**—Dr. Abbe reported this case. He said the patient was a young man of 18 years. He had had a fall two years before, but noticed no trouble and was perfectly well. About a year previously he noticed a swelling over the clavicle which was diagnosed as a sarcoma. This was a very grave matter for his family, who were distressed beyond words. They came to Dr. Abbe to see if anything could be done for the sarcoma. Photographs showed the clavicle raised one and one-half inches above the normal place, and above the clavicle a mass of hard bone development. There was a slight curvature of the lower part of the neck. A possible fracture was thought of, but this idea was abandoned. Diagnosis of a supernumerary cervical rib was made, and an *x*-ray picture showed the following unusual condition: There was an abnormal partial development of three cervical vertebræ, and three ribs were fused together. Two ribs formed a Y-shaped development. The seventh cervical was normal, but the first, second, and third were fused together. Ribs 1 and 2 were fused into one; and 3 and 4 fused into one at the spine. On the other side 1 and 2 were fused, but 3 sprang into an arch and fused further out from the spine. The condition was entirely a congenital defect, and not at all common. In the picture one cervical vertebra looked as if it had been fractured, but that was due to development. The supraclavicular space was filled with a hard mass of fused bone. Growth of the lower spine had caused distortion of the fixed ribs and clavicle. The normal, rapid development of the young man had caused the distortion to appear very recently. The serious suspicion of bone sarcoma was thus corrected by well-taken radiographs, greatly to the relief of the family.

Dr. Gibson said it was remarkable how many cases of cervical ribs and other congenital defects had been noted with the introduction of the *x*-rays. He had seen three cases this year. A man had come to his surgical clinic who had been refused for life examination. He had a swelling in the neck, which was painful, and supposed to be tuberculous. The pain was on both sides. By *x*-ray examination it was shown that the man had a cervical rib.

Dr. Huddleston said there had been six or seven cases of cervical ribs found at the Gouverneur Tuberculosis Clinic, in the course of lung examinations which had been confirmed by the *x*-ray. A number of such cases could probably be found at any tuberculosis clinic.

Dr. Thompson said he had recently shown two cases of cervical ribs in his clinic. He added that Dr. Abbe's case showed that patients suddenly became aware of some deformity they had always had. He had had a young woman patient who had always had enlarged cervical ribs, but not until she had reached the age of going to dances décolleté had she come with alarm to get advice on the "tumor" in her neck.

**Osteitis Deformans.**—Dr. W. Gilman Thompson presented this case (see page 832).

Dr. Gibson said he had seen several cases of this sort and would like to know now to cure them.

Dr. Bryant said he was very much pleased to see the case that Dr. Thompson had presented, but he would like to call attention to certain points. There appeared in the illustrations presented no involvement of the joints, particularly the humerus, as in osteoarthritis, which was a very common disease, and these radiographs showed very clearly the distinction between the two diseases.

Dr. Brannan said he would like to ask what the cause of the bowing was, if it was known.

Dr. Abbe said he had had a patient last month who had had an enormous thickening of the skull, with no apparent symptoms of any cerebral disturbance. There was no other evidence of disease, and the patient was a perfectly healthy man. The entire skull was increased in thickness one inch, but the head was not apparently enlarged; he wore the same sized hat. The only symptom was a slight humming in the ears, as if perhaps one of the arteries was thickened. There was no sign of acromegaly, the pituitary space being normal.

Dr. Thompson said in reply to Dr. Brannan that the bowing was perhaps due to the weight of the body, but not always so, because the bones in the arm showed bowing and the weight of the body clearly did not explain this as well. It was probably due to the deforming process going on in the central canal. The bones were apt to show distinct modules almost as hard as ivory. The long bones also showed areas of softening and were sometimes very friable. In some cases spontaneous fractures occurred. In the case in point the patient said she had had fractures, but she exhibited such childishness, and her history was so very unreliable, that it could not be taken seriously. For instance, she said she had had a fracture of the thigh in the middle of the femur, and had had no treatment, but had been able to walk about. The woman felt perfectly well and was quite persuaded that she had no disease at all. She did not have any of the serious muscle pains accompanying most cases of this disease.

In 1904, Vincent, a Frenchman, in a Paris Thesis, stated that the disease had probably a dystrophic origin in

the central nervous system, and he regarded the fatigue and the diminished knee jerks as evidence of dystrophy. Nothing was known of the etiology of the disease or of a cure. It was not known definitely to be associated with disease of the ductless glands. There were two or three cases associated with disease of the pituitary body, and fourteen cases associated with sarcoma or carcinoma. It was evident from the pictures shown that there was no involvement of the joints, so that the patient had complete use of all joints.

In reply to Dr. Abbe, Dr. Thompson said that he had no doubt the case he mentioned was one of osteitis deformans. There had been two such cases, classed as osteitis deformans, with no involvement of the long bones. These cases were not difficult to distinguish from acromegaly.

**Consultations without Scars.**—Dr. Joseph D. Bryant read this paper (see page 829).

Dr. Kinnicutt said he had to thank Dr. Bryant for presenting the subject in such a delightful way. He thought no one would disagree with what he had expressed in his paper. The whole matter was a delicate one, but the last sentence expressed what they all felt—that the code of ethics would be unnecessary if the golden rule were carried out.

Dr. Ewing said he could not apply Dr. Bryant's remarks to laboratory men, as they did not get such complex ethical questions in the laboratory. He had, however, listened with much profit to Dr. Bryant's paper, and especially to the reference to the difficulty at times of offering a sympathetic tribute to a colleague's work.

Dr. Cleveland said he had listened to the paper with interest and thought it was a very timely presentation of the subject. It was most necessary, and he hoped that when it was published it would be thoroughly read. He thought there were often great lapses in rules of professional etiquette. He, personally, felt grateful to Dr. Bryant for his interesting paper.

Dr. Murray said it was some comfort to him to know that other places had troubles similar to those at his home city, Halifax. When a young man practising it was not long before he had to face some such question. Dr. John Stuart was his first consultant. He was a classmate of McKenzie, a thorough gentleman, and a man of great medical ability. With him one could never imagine any trouble arising. Dr. Murray said that he had settled in his own mind that it was a matter of individual character that made difficulties in the profession. One consultant had sent flowers to his best patient.

Dr. Gibson said he did not know much about ethics. He had had a set of rules when he was a student, with one appropriate to every occasion, but he had been waiting to apply them ever since. He had read the rules of the A. M. A. and they made him think of the sign which read "Gentlemen will not spit on the floor; others must not."

Dr. Thompson said the paper was very interestingly presented and he was very glad to hear from one who had had so large an experience as Dr. Bryant. He did not think that there were many serious lapses from ethics, or that the physicians were as responsible for the lapses as the patients themselves, who went to so many different specialists and so often took matters in their own hands. In many consultations the diagnosis was already well known and the consultation was more for the general satisfaction of the family, there being no room for disagreement. This was largely due to the increase in laboratory investigation, which rendered diagnosis much more accurate. Originally a consultant was called in because of exceptional experience in diagnosis. Today he was called because the family did not think the recovery of the patient was as rapid as it might be. The consultant was submitted to a cross-examination by the family that sometimes made it difficult for him to live up to standards of ethics, although he might make every effort to do so. He thought that any effort to add to the dignity of the profession in these lines was an important one, for the rising generation of medical men especially.

Dr. Smith said he had been thinking during the reading of the paper of the position in which the consultant was placed by the laity. He tried to show civility to another medical man, and the patient and the patient's friends thought nothing of medical ethics at all, and did not care if the consultant was uncivil to his colleagues. This had happened to him. The attitude of the laity in this respect emphasized what Dr. Gibson had said. Thirty years ago the term "code of ethics" was like a red rag to a bull. It had been compromised. He confessed that it surprised him when a member said that he had had no experience with ethical questions.

Dr. Abbe said he thought that the present division of practice into specialties had made it easy for the specialist to get too much interested in a case presented to him for an opinion. He thought he could do it more good than the attending physician. He could not get away from the case. He was not wicked in intention, but he sometimes forgot the injunction "Thou shalt not steal." He did not mean to steal, but he was so interested that he ran the risk of forgetting.

Dr. Miller said he thought the younger members of the profession should find Dr. Bryant's paper valuable and timely and he wished to express his appreciation of it. He would like to ask Dr. Bryant a question, the answer to which might prove of use to other men. He had been asked to go into consultation in a rural community, where a local man's reputation was more often easily damaged than in a large community. He was asked to see a patient who had been kept in bed, with two or three trained nurses to take care of him, and who had not been allowed to move hand or foot, on the supposition that he suffered from serious, organic, cardiac disease. Dr. Miller was unable to find evidence of such a condition. The local physician was evidently sincere in his belief that the condition existed. He (Dr. Miller) had to be honest with the patient but at the same time try to do the right thing by the local doctor. He told him what he thought about the case and left it to him to explain it to the family. Some suspicion, however, seemed to have been aroused in their minds, for another consultant was called from the city. He, agreeing with Dr. Miller, said very frankly what he thought. Dr. Miller later learned that the case passed into the hands of the second consultant. That was a difficult situation, for in trying to be fair to the physician he ran the risk of not being fair to the patient or to himself.

Dr. Brannan said it seemed to him that Dr. Miller had not done himself justice and had hardly done justice to the patient. He would have insisted that the patient learn his views and make gradual change in his mode of life.

Dr. Miller, replying to Dr. Brannan, said that that was practically what had been done. Suspicion was, therefore, aroused and the local physician no doubt had lost prestige because of it.

Dr. Bryant said Dr. Miller was right to apply the idea of his conscience to the question. He hoped the principles of ethics were usually complied with and that what he had said would operate to make more medical men think about them. To the younger men they were suggestive of great guiding importance, and once a week he read fifteen minutes to the graduating class from the principles of ethics. Their ignorance on questions of an ethical nature was amazing.

Dr. Polk said he always liked to disagree with Dr. Bryant if he could. Dr. Bryant seemed to think that doctors were less thought of than clergy and lawyers. He did not think so himself. He thought that lawyers were worse thought of than doctors. As to the clergy as far as he could see, religion was getting pretty dim on the horizon. Man, as distinct from "God," was at the top all along the line. Every one seemed bent on his own individual conception of right and justice. He used any code that suited his own convenience. That might seem pessimistic, but if we stopped to listen and think, many of us would approximate this statement in our conclusions. There was a kind of human upheaval going on that took itself too seriously, and had reached the conclusion that it was self-sufficient in every direction. In consequence of this the legal profession had perhaps suffered more than the medical. He was not criticising the legal profession, but he thought that if you wanted to find evidences of lack of ethical methods of thought and conduct that affected the situation vitally in any and every community, you would find it in the legal profession. They should be the custodians of our morals and should stand for more things than those which touch our pockets. Man was not controlled by morals alone, but by the law as well, yet one could find a situation in which the law had been used for the purpose of showing people how close they could run to the penitentiary and yet evade it. This had demoralized the community as a whole.

---

**Tuberculous Colitis and Pericolitis.**—Piéry and Mandoul on the basis of observations made on 20 cases conclude that a new painful intestinal syndrome may be described. This is designated "tuberculous mucorrheic enterospasm." This is often a manifestation of the inflammatory tuberculosis of Poncet and Leriche. A large number of cases of plastic colitis and pericolitis are similarly the result of an inflammatory tuberculous process. In many cases of Hirschsprung's disease a tuberculous factor is present.—*Revue de Médecine.*

### ABORTIVE PULMONARY TUBERCULOSIS.

BY MAURICE FISHBERG, M.D.,

NEW YORK.

ATTENDING PHYSICIAN, TUBERCULOSIS WARD, MONTEFIORE HOME AND HOSPITAL.

THE prevailing notion among the laity, as well as among many physicians, is to the effect that once the tubercle bacillus has been implanted in the human body, especially the lungs, a well known disease will soon manifest itself; that this disease will pursue a certain course, variable to be sure, yet always progressive, and terminate fatally unless checked by appropriate specific, medical, dietetic, climatic, or institutional treatment. In former years medical men held that tuberculosis is invariably fatal but we know at present that a large proportion of patients recover, and judging from records of autopsies made on persons who died from all causes, more persons recover from, than succumb to this disease. But among medical "survivals," of which there are many, the idea that tuberculosis is invariably a progressive disease is one that has not been combated to the extent warranted by facts observed in the daily practice of every physician and especially while making autopsies on persons who died from causes other than tuberculosis.

The average duration of a case of pulmonary tuberculosis has been variously estimated by different authorities. Some state that it is not much over one year, while others believe that it extends to five, seven, and even ten years before it terminates fatally. But these estimates are based on fatal cases and can not give a real idea of the duration of the tuberculous process in the human being. They leave out of consideration the large number of cases running a benign course for years, and when death supervenes, it is usually due to a cause other than tuberculosis. These benign cases will be discussed in another paper, but here we are concerned with the abortive type of this disease, which is characterized by the short duration, one to three or four months, but which invariably recover, without any special treatment.

It is well known that most infectious and contagious diseases quite often pursue an abortive course—*i.e.* recovery takes place sooner than would be expected in a typical case. Thus, measles is known sometimes "to abort early in the eruptive stage, and convalescence begins about the second day of that period. Occasionally, during an epidemic of measles, cases characterized by fever, coryza, bronchitis, and gastric derangements, but without any rash are met with; as these patients are found to be immune on subsequent exposure to the infection of measles a possibility of the occurrence of measles without rash must be admitted."[1] Similarly there are abortive cases of scarlet fever. In some undoubted attacks the whole duration of the febrile stage may not extend over three days, occasionally it is even less.[2] Cases of smallpox without eruption are also known, and they may be of a very mild type and run a short course. There are also known abortive or one or two or three-day pneumonias[3] as well as cases of chancres which are not followed by secondaries or tertiaries. Abortive tuberculosis, in which the disease runs a short course and soon terminates in complete recovery, should also be expected if we bear in mind the large number of persons who at autopsy show healed tuberculous lesions in their lungs, though during life they have never suspected that they were infected with the tubercle bacilli. But clinically it appears that this type of pulmonary tuberculosis has not been described. Thus consulting the treatises on this disease which I have at hand, I find no mention of this type of tuberculosis in nearly all of them. Charles L. Minor[4] is one exception; he says that "a certain number of cases are latent or abortive, though they need not be made into a special class by themselves; the initial symptoms which are often not recognized at all, slowly disappearing either before or after a positive diagnosis can be made. The cough ceases, the weight returns to normal, and the process is either arrested permanently—these cases being those in which autopsy reveals old scars in apices—or for many years, to break out again during some period of depressed vitality." On the other hand I find that Cornet in the second edition of his great work on tuberculosis[5] devotes a paragraph to this type of the disease and says that the abortive course of tuberculosis, which Bard and Meissen have described, should be considered a special type. In these cases there is but little destruction of lung tissue, only at the apex, or in the bronchial glands; the process, however, is short lived under the influence of therapeutic measures or, what is more often the case, the lesion heals spontaneously, leaving behind a chalky deposit, or a smooth fibrous scar.

This type of pulmonary tuberculosis has also been described by Neisser and Bräuning, who have coined the term "tuberculosoid" to express a common class of cases in which the patients present subjective and objective symptoms and signs of tuberculosis, but recover under any form of treatment, or spontaneously, within a short time and remain well indefinitely. The lesion remains small and circumscribed, and either heals or passes into a latent phase.[6] That this type of tuberculosis is not rare is evident from the fact that among the 1,900 persons who were treated at the tuberculosis clinic at Breslau during ten years, Neisser and Bräuning found 300 who presented tuberculosoid condition, and examination from four to ten years

later has shown that they were nearly all well. In those that died from some intercurrent affection, the findings were those which Naegeli described.

It was Bard, however, who first described this mild form of tuberculosis and he named it "tuberculose abortive."[7] He puts in this class all cases of tuberculosis in which the lesion is circumscribed, of little activity, often altogether latent, and which quickly cicatrize and are found at autopsies in the shape of more or less extensive scars, located at the extreme apex, which have healed perfectly. He points out that most of these cases of abortive tuberculosis are not diagnosed during life because they present indefinite symptoms and signs, passing off as ordinary "colds." Those that begin with hemorrhages can be recognized and should receive attention, according to Bard.

Following Bard several other French clinicians have spoken of this form of tuberculosis and Piéry in his recent treatise devotes a chapter to the abortive type of the disease.[8] He shows that at autopsies abortive tuberculosis reveals itself in the form of puckering cicatrices at the apex which produce more or less deep depressions on the surface of the lung and which are surrounded by emphysematous air vesicles. These changes, according to Beriel, contain often smooth fibrous bands, or cheesy, chalky, or calcareous nodules. Cicatrices of the same kind may also be found in the pulmonary parenchyma. In the pleura and subpleural tissue are also found isolated fibrous or calcareous granulation, forming well defined nodules. These are the gray or white miliary tubercles forming indurations which are felt by the fingers passing over the serous surface. Abortive tuberculosis may also leave behind dense areas of slaty chronic indurative pneumonia, containing in their center one or more calcified, encysted foci, sometimes dilated bronchi, or smooth cavities.

I met with cases of abortive tuberculosis in a peculiar manner. As physician to the United Hebrew Charities in New York City, I have annually under my care several hundred cases of tuberculosis in all stages of the disease. They are recruited exclusively from the poorest strata of the population of the lower East Side of Manhattan. Their occupations are mostly of the class which has the evil distinction of figuring in the etiology of tuberculosis as "predisposing," or of aggravating the course of the disease in case of infection, especially when the patient persists in pursuing his vocation. When I began this work twelve years ago, influenced by the teachings of the literature on tuberculosis, which by the way is mostly written by physicians whose experience has been gained in sanatoria, I expected to see every consumptive succumb within a few months, unless vigorous measures were taken to check the disease and to change his mode of life. Considering the congestion in the tenements and the overwork in the sweatshops, as well as the deleterious effects of poverty with its concomitant starvation, I always urged it as imperative that all cases of tuberculosis be removed to sanatoria. In a large proportion of cases this was done—the patients were removed to some excellent institutions where they remained for months, often for more than a year. Within a few months after they returned to the city, immaterial whether they again engaged in indoor occupations or not, I was struck with the large number of relapses which occurred among these "cured," or "arrested," cases, and often the idea presented itself to me whether those whose practice is confined to institutional care of tuberculosis realize the futility of their methods in a large proportion of cases, particularly among the poor.

On the other hand, I was impressed with the large number of tuberculous patients that came under my observation and who for various reasons were not admitted to sanatoria, but continued in the tenements and the sweatshops, yet held their own for years. Many patients in whom a positive diagnosis of incipient tuberculosis was made but no treatment instituted, were found several months later in excellent condition, none the worse for their experience. Often because of the limited capacity of the sanatoria at our disposal our applicants' names are placed on waiting lists to be notified whenever a bed becomes vacant, which occasionally took from two to three months after the first application was made. I was quite often surprised when the applicant was called to be sent out of town to find that all the symptoms and signs of active tuberculosis, which were clear during several examinations two or three months ago, had entirely disappeared, and the patients felt quite well. Moreover they told me that they had kept on working all that time and had not been under the care of any physician. I have also met with many cases of spontaneous recovery from pulmonary tuberculosis in my private practice; patients who got over attacks of hemorrhage, cough, night-sweats, etc., within a few months without any special treatment, remaining well for years.

One of the cases of abortive tuberculosis that I had an opportunity to study thoroughly was the following:

E. G., a physician, 32 years of age, working quite hard at his profession, suddenly began to spit blood on March 7, 1904. Physical examination showed a distinct lesion of his right apex; a laryngologist found that the blood came from beneath the glottis. The physical signs indicated infiltration of the right apex manifesting itself through laggings, defective resonance, bronchovesicular breathing, crepitation, whispered voice, etc., at that area, especially posteriorly. The temperature, taken for two months every two hours when not sleeping, was usually subnormal in the morning, often as low as 97° F. but went up to 100° F., or 101° F. in the afternoon, particularly after exertion. Quite profuse night-sweats were of daily occurrence. His appetite was, however, not impaired and his bowels regular. Repeated bacteriological examination of the sputum which was quite profuse gave negative results. The patient continued working at his profession, though with less intensity, and within three months all his subjective symptoms disappeared; his cough, fever, night-sweats, etc., left him. At present, eight years after that hemorrhage he feels in excellent condition, his weight is 170 pounds, 25 pounds more than before his attack of tuberculosis. Physical examination shows some sibilant rales at the right supraspinous fossa, as well as some impaired resonance. That this was a case of tuberculosis, although no tubercle bacilli were found in the sputum, is attested by the fact that three excellent diagnosticians, as well as a laryngologist, considered it such. I was inclined to doubt the correctness of this diagnosis, but meeting with many other such cases, I am now strongly of the opinion that it belongs to that class of abortive tuberculosis which is so rarely mentioned in medical literature.

A case in which the objections that can be raised in the preceding case are wanting is the following:

C. E., a woman 27 years of age, married five years, but no pregnancies because of atrophy of the testicles of her husband. Family history negative. Consulted me August 5, 1911. Had a profuse hemorrhage two weeks ago, and gives a history of three similar hemorrhages during the past five years. Coughs since the last hemorrhage, has fever, malaise, night-sweats, etc. Has lost seven pounds in weight within two weeks. Examination shows dullness of the right upper lobes both anteriorly and posteriorly, true bronchial breathing, some crepitation and whispered voice at the same area. Examination of the sputum shows the presence of tubercle bacilli. The patient was advised to stay in bed for two weeks and given the usual treatment in such cases. When she reported again at the appointed time, I found that the fever had left her altogether, her appetite improved, her general condition was that of well being, and while the dullness on the upper part of the right chest persisted, yet the bronchial breathing changed to the bronchovesicular type, and no rales could be elicited. This woman has been under my care ever since and at the last examination, December 20, 1913, I find that she has gained eighteen pounds in weight, as compared with her weight when I saw her first. She has not coughed, nor felt out of sorts seriously during the last fifteen months. The dullness has persisted to date, and auscultation shows prolonged expiratory murmur at the right apex. There is no doubt to my mind that this woman passed through an abortive attack of tuberculosis and was cured in about three months.

Another abortive case of tuberculosis taken at random from my case histories is that of J. R., 25 years of age, tailor. Family and personal history give nothing which may have any bearing on his troubles which brought him to my office, December 9, 1911. Has been coughing for three weeks, ever since he suffered from an attack of "grippe." The cough annoys him especially at night, and on one occasion he noted some streaks of blood in the sputum he brought up. Complains of pain in the left chest, extending as far as the shoulder. Appetite fair, bowels regular, but has been feeling out of sorts, unable to do a good day's work during the last two weeks. A feeling of languor overtakes him every afternoon and he is inclined to sleep at that time. Night-sweats have been noted only the last two nights, and this frightened him so much that he came to have "his lungs examined." Physical examination shows a pulse rate of 108, increased to 124 on slight exertion; signs of infiltration with retraction of the left apex and also defective motion of the base on the same side. Microscopical examination shows the presence of tubercle bacilli. The usual routine treatment was prescribed for this patient, and he showed improvement within two weeks; his cough disappeared within a month, and he gained twelve pounds in weight; his night-sweats also ceased. The few crepitant rales that were heard one month ago, have also gone but the bronchial breathing, and the dullness have persisted to the last examination on September 8, 1912. On the whole the patient feels well, and has been working at his trade all along.

A striking case of abortive tuberculosis was that of A. F., a clothing manufacturer, 40 years of age, who suddenly, without premonition was seized with a profuse pulmonary hemorrhage on September 5, 1911. He was referred to me by a colleague, and when I reached him I found him in actual collapse, not so much from the loss of blood as from fright. No thorough examination of the chest could be made at that time, but auscultation of the anterior aspect of the thorax suggested a lesion at the left apex. The hemorrhage continued for ten days, some days it was quite profuse, and for ten subsequent days he continued to bring up blood-tinged sputum. Of three specimens of sputum examined, only one showed the presence of tubercle bacilli, about five to a field. His temperature was that of a typical case of incipient tuberculosis, often subnormal in the morning, and reaching 102 F. in the afternoon and evening, and had severe night-sweats. After he remained in bed for a month, and no blood was seen in his sputum for ten days, I carefully examined his chest and found physical signs of infiltration of the left apex. He was quite run down for his experience, having lost fifteen pounds in weight during the month he had been confined to bed with the hemorrhage. I advised him to leave the city, and he went to Lakewood, N. J., returning within a month, reporting that he had regained his weight and strength and feeling in excellent condition. Examination of his chest at that time showed signs of cicatrization at the left apex—no crepitation, only some sibilation and defective resonance on percussion, but by far not as intense as during the examination five weeks before. I have seen this patient five times since then, but found him just as well as could be expected of one who never had tuberculosis; even the rapid and unstable pulse, which was quite pronounced in this case, has become normal. It is his own opinion that he never felt better in his life.

A case under my observation for eleven years illustrates the benign course of tuberculosis in some cases better than those just detailed. N. D., 29 years old, carpenter, called to see me July 15, 1901. He came from bad stock—his father died at the age of 38 from "hemorrhage"; of seven children born to his mother only two survived, the rest have died—one from meningitis (tuberculosis?); two from endemic diseases during infancy; one, who was crippled from hip joint disease, succumbed through an accident; and one, a sister with whom my patient lived during the last five years in New York, died from pulmonary tuberculosis three months ago. Personally my patient has been very much addicted to "colds," especially during the spring months. But these colds usually passed off within a few days, a week or two. But the present cold, contracted last March, when he was said to have had "grippe," has persisted. He coughs, has night-sweats, feels flushed and tired every afternoon, and has lost twelve pounds in weight during the last four months. Examination showed signs of infiltration of the left apex down to the third rib anteriorly as well as dullness at the right interscapular space which I consider a good sign of bronchial adenopathy. An examination of his sputum revealed a moderate number of tubercle bacilli. I urged him to give up work and go to the Catskills, which he immediately did. But he returned within ten days, saying that he can not remain in the mountains, where he is lonesome, and inasmuch as he feels strong enough to work for his family, he prefers to do so. He insisted that the idleness in the country makes him sick. He has kept at work ever since and comes to see me whenever his cough annoys him excessively. I have made it my business to examine his sputum

whenever available, and of fourteen such examinations, only on two occasions were tubercle bacilli found—once in July, 1901, and another time in April, 1902. When I saw him last, during November, 1912, he presented signs of fibrosis of the left upper lobe, but his sputum, which is rather scanty, was negative of the Zihel-Nielsen strain. His weight was 156 pounds, as against 136 in 1901. The diagnosis in this case was as reliable as can be expected, based on both clinical and bacteriological findings. The course was that of an abortive case, recovery taking place in about three months and for eleven years there was no recrudescence, the patient working at his trade all along.

Another case running an abortive course was that of A. C., Russian, 22 years old, works at leather goods; has been in the United States but one year. His family and personal history are negative—has always felt well until February 14, 1910, when, without premonition, he began to bleed from his throat while at work, losing about four ounces of bright red blood, and continuing to expectorate blood streaked sputum for three days. At one of the tuberculosis clinics, where he immediately went for advice, he was told that he has tuberculosis. He consulted me for the first time on February 17, when upon physical examination I found a short note at the left supra and infraclavicular space to the second rib, narrowing of the field of resonance (Krönig's sign) bronchovesicular breathing and whispered voice posteriorly and some crepitation anteriorly on the left side. He complained of a dull pain in the left chest. His appetite was excellent and his bowels regular, but he informed me that he had been losing in weight ever since he came to New York one year ago. Microscopical examination of the sputum was on four different occasions negative as regards acid fast bacilli. During the first fortnight that I had him under observation I found an elevation of his temperature of one or two degrees above normal every afternoon, but thereafter it was always normal. Since then his strength returned, his weight increased so that on September 12, 1912, when I saw him last, his weight was 139 pounds, as against 124 in September, 1910. I also found that the short note at the left apex gave place to slight hyperresonance, but the prolonged expiratory murmur persisted and in addition there was some sibilation where formerly there were found crepitations. This patient wanted to return to work two weeks after he was under my care, but his fellow workmen, who have heard so much about the dangers of infection, refused to work with him, and it took him six weeks to find a new job in a factory where his troubles were not known. At any rate, this patient has been idle about two months and without any special treatment, and in spite of his life in an East Side tenement, recovered completely during that short period. Had he gone to a sanatorium, which would have been the case had this patient not feared deportation in accordance with the United States immigration laws, institutional or climatic treatment would have been credited with the cure.

A case of abortive tuberculosis under my care which was studied as thoroughly as could be expected was that of C. L., a dentist, 24 years of age. His family history was negative, as was his personal history, excepting that he had been subject to "colds" which annoyed him during the winter months. On the 25th of April, 1911, after an annoying cough of two weeks duration, he suddenly began to expectorate bright red blood in moderate quantity. This hemorrhage continued for three days, and for three subsequent days he kept on bringing up blood-streaked sputum. Excepting the cough he felt well, his appetite was good and he told me that he never felt better. Physical examination of his chest showed marked dullness at the left apex, Krönig's sign, both anteriorly and posteriorly, and true bronchial breathing down to the second rib in front and the spine of the scapula behind, and also some tubular breathing in the left interscapular region. No adventitious sounds could be elicited even after cough, but whispered bronchophony was quite pronounced. All this indicated infiltration of the left apex, and probably enlargement of the bronchial glands. His temperature, taken every three hours for three weeks, showed the characteristic remittent curve, normal in the morning, rarely one degree subnormal, and rising one or two degrees in the afternoon and evening. Only on two or three occasions had the patient noticed night-sweats. Repeated examination of the sputum gave negative results bacteriologically, but the albumin reaction was positive. During the six weeks following the hemorrhage this patient had an excellent appetite and in spite of the superalimentation in which he indulged at my advice, he did not gain in weight, in fact he lost three pounds. But within two months the physical signs of infiltration of the left apex disappeared—instead of dullness I found hyperresonance, and instead of bronchial breathing, vesicular breathing with prolonged expiration which persists to date; the whispered voice also remained, though with less intensity. He works at his profession and considers himself well, which he undoubtedly is.

Not all the cases of abortive tuberculosis begin with hemorrhage—in fact I believe that the vast majority of abortive cases never bleed, but we do not recognize them because they pass through the infection without any symptoms which would direct attention to the lungs. But sometimes we may be able to follow this form of tuberculosis quite closely and make a proper diagnosis. This is especially true of cases following influenza which often show signs of apical infiltration, but which clear up within a month or two. Inasmuch as tubercle bacilli are not found in the sputum in this sort of cases, it is almost invariably thought that post grippal coughs with apical signs are hardly ever tuberculous. I suspect that many of these cases are of the type of tuberculosis discussed in this paper and that they pass unrecognized. The following case illustrates this point.

M. S., 46 years of age, has been my patient for fourteen years, has always been troubled with coughs during the winter months, and shows signs of pulmonary emphysema ever since I knew him. In November, 1911, he was laid up with characteristic symptoms of influenza, running a rather high temperature with all its concomitants—anorexia, pain in the limbs and back, cough, profuse expectoration, etc. After remaining two weeks in bed his temperature became normal and though debilitated and sick, he returned to his business. But within a week he had to give up work, because of lack of strength and vitality. Physical examination at that time revealed, in addition to the signs of emphysema, evidences of infiltration of the left apex—dullness, bronchial breathing, whispered voice and subcrepitant râles, all localized above the second rib. In addition to Krönig's

sign, there was also some defective motion of the base at the left side, which I was sure never existed in that patient before. Tachycardia was very pronounced in this case—the pulse rate was over 100 during rest and the least exertion increased it very much. Although he expectorated profusely muco-purulent material, repeated bacteriological examinations, once with the antiformin method, failed to show tubercle bacilli, his night-sweats were very severe—some nights he had to change his bed clothes two or even three times. Anorexia was extreme and his cough very annoying and difficult to control with the usual anodynes, and the dyspnea pronounced—after exertion alarming. His temperature again began to run a remittent course, subnormal in the morning, and two or three degrees above normal in the evening. Thus he remained in bed for four weeks, and when his temperature was normal for ten days, and he left his bed, it was found that he had lost twenty-eight pounds in weight during the last three months. He spent three weeks in a winter resort in the neighborhood of this city returning somewhat invigorated, yet suffering from dyspnea, and instability of the pulse and temperature after the least exertion. He continued attending to his business and yet the improvement in his general condition kept up, and while he was slow in regaining his lost weight, his strength returned after a vacation during the summer. He surprised me when he brought a new life insurance policy which was issued after an examination by a physician living in the country place where he spent his vacation. An examination at that time showed that the dullness at the left apex had disappeared and the signs of pulmonary emphysema were again evident all over both sides of the chest, as I knew to be present before the illness of last winter.

The post-grippal cases of abortive tuberculosis are very frequent in my experience. I meet with them especially among artisans of the garment industry in New York city. Many present symptoms and signs of incipient tuberculosis which last but a month or two and recover without any special treatment. I have known some who persisted working in sweat-shops while coughing and having mild fever, yet recover in a short time. The large number of persons among this class of workers at indoor and dusty occupations who show auscultatory and percutory signs indicating differences between the sides of the chest, are good proofs of the frequency of abortive tuberculosis among them. Among the poor and dependents who apply for relief to the United Hebrew Charities in New York city I have also seen many cases of abortive tuberculosis, and it seems that poverty, malnutrition, overcrowding, etc., are not always instrumental in bringing about an acute course of tuberculosis when a person is infected.

From the few cases detailed above it is evident that we are dealing with a distinct group of cases of tuberculosis which run a short and benign course terminating in recovery within two or three months. To be sure we have known all along that very few persons pass through life without being infected with the tubercle bacilli, as is evident from autopsies made on thousands of persons who died from all causes. The positive reaction found in over ninety per cent of humanity to some of the tuberculin tests, notably von Pirquet's, is another proof of the large number of people who have been tuberculosis without showing clinically any symptoms. Some of these cases can be recognized during their period of active infection, if we paid more attention to "neglected colds," obscure attacks of "grippe," "rhinopharyngeal coughs," pulmonary hemorrhages, which are supposedly due to causes other than tuberculosis, etc. Many of these cases could be diagnosed as abortive tuberculosis, if a careful seach for symptoms and signs was made. Moreover, I am under the impression that many of the cases in which a diagnosis of tuberculosis is made by a competent physician, but the subsequent course of the disease has thrown some doubt on the correctness of the original diagnosis, are cases of abortive tuberculosis. A large proportion of cases admitted to sanatoria, but soon discharged as non-tuberculous, also belong to this class. I have also seen many patients making applications for admission to public sanatoria and passed upon by the examining physicians as incipient tuberculosis and eligible, but inasmuch as the institutions are overcrowded, they have to wait for weeks or months before beds are vacant for them. When they finally present themselves for admission it is found that all the signs and symptoms observed a few weeks before have disappeared. In such cases I formerly believed that the original diagnosis was erroneous; that an "apical catarrh," a "local bronchitis," or pleurisy, etc., was mistaken for incipient tuberculosis. But I now look upon many of these cases in which the lesion, instead of pursuing its normal course, has healed quickly as aborted cases of tuberculosis, just as we have aborted cases of measles, scarlet fever, syphilis, pneumonia, etc. When carefully examining these persons we may find some differences in the auscultatory and percutory signs when the two sides of the chest are compared, thus indicating the presence of healed lesions of tuberculosis.

The symptoms and signs of abortive tuberculosis are practically the same as those of incipient tuberculosis as described in standard text books on the subject. But they never pass beyond the stage of incipiency. The vast majority of cases can not and are not recognized clinically. It is different with those that have hemorrhages, and most of the cases detailed above began with more or less profuse bleeding. The bleeding lasts a few hours or days and either stops abruptly or continues for some days in the form of expectoration of blood-streaked sputum. Every physician has among his clientele patients who have had pulmonary hemorrhages years ago and have felt well ever since. There are also many patients who have had hemorrhages many years ago, but recovered shortly, feeling well for a long number of years, to be finally attacked with phthisis. In such cases the first hemorrhage was probably due to an attack of abortive tuberculosis, while the second or third attack was not aborted, but pursued its usual course.

Some may never have fever, but these are not recognized and pass as ordinary "colds." In many the fever may pass unrecognized because a careful search is not made for it. Just as in all cases of incipient tuberculosis, it is advisable to take the temperature every two hours and after some exertion on the part of the patient before deciding that the temperature is normal. While many cases show a subnormal temperature in the early morning hours, it can not be said that all are thus characterized. Tuberculous fever, it is well known, does not run a definite and characteristic course, but is always irregular and capricious and this is to

be borne in mind when considering the abortive cases. I place great reliance on the excellent appetite some patients have in spite of the fever as almost pathognomonic of tuberculosis. Some of these febrile cases are troubled with the usual symptoms of fever—malaise, lassitude, languor, pain in the limbs, backache, etc.

Night-sweats are observed in most of the cases. In some this symptom is overlooked because of its mildness, while in others it may be quite profuse and so pronounced as to be the main concern, as was the case with one of my patients.

Cough is a constant symptom, though in some cases it is so slight as to be overlooked by the patient who says that he does not cough, but when carefully questioned he admits that he has to clear his throat in the morning, and occasionally coughs during the day or night. We often meet with the dry, hacking cough annoying the patient all through the day, or keeping him awake during the greater part of the night. Especially is this the case with nervous patients, frightened by a pulmonary hemorrhage. In cases following influenza the cough may be loose, productive of abundant sputum, which though not characteristic yet is never purulent in abortive tuberculosis. Some are also hoarse intermittently, the hoarseness lasting a few hours during the day, or for several days in succession. Most of the abortive cases are of the "closed" variety of tuberculosis, but now and then we meet one showing tubercle bacilli in the sputum, and most of the cases reported in this paper have been of this sort. The albumin reaction, which I consider of great diagnostic significance [9] is almost invariably positive in abortive cases in which sputum is available for analysis.

Weariness or languor is also seen in many cases. The patient while not completely incapacitated by sickness yet feels tired during the afternoon, but recuperates in the evening, or feels refreshed after a night's sleep. The digestive organs are practically normal in function. The anorexia, which is so common in progressive phthisis, is usually absent in the abortive cases. The patients eat well and when superalimentation is urged they can easily carry it out. It is, perhaps, for this reason that most of the abortive cases are not emaciated and even gain in weight quite soon, in some cases while continuing at work.

Tachycardia is a frequent symptom—all my cases had a pulse rate of 90 or more per minute. Another feature of the pulse is its instability, its rate increases with even slight exertion, and comes down after rest. But the rapid pulse is not of long duration: Within a few weeks, going hand-in-hand with the general improvement, the decline in the fever, gain weight, etc., it slows down, becoming normal again. Indeed, in all cases of incipient tuberculosis in which the pulse slows after a period of tachycardia, I always look forward to a speedy recovery. The same is true of the blood pressure. It is, like in most cases of tuberculosis, rather low, between 65 and 90 mm. of mercury, and rises again with the general improvement. But there are many cases in which the blood pressure is normal, or even above normal. Dyspnea is rare. One exception that came under my observation was a case of abortive tuberculosis implanted on an emphysematous lung, but the patient recovered within ten weeks, and has been well for eighteen months.

The physical signs of abortive tuberculosis are, like the subjective symptoms, those of the classical incipient cases of tuberculosis. Of course, in the cases in which the lesion is of small extent, we may not find any signs on auscultation and percussion, and without hemorrhage the diagnosis cannot be made with any degree of certainty. In all probabilities the vast majority of tuberculous infection of the lung in man are of this character. They are aborted without making themselves known in any way. In some the conglomeration of tubercles is large enough to give definite physical signs which may be detected when carefully looked for. In these cases we may have either a short note or defective resonance of the affected apex above the clavicle, or beneath the inner third of that bone. Krönig's method of finger to finger percussion reveals a narrowing in the resonant area at the apex when compared with the opposite side, which is one of the best signs at our command, provided, of course, we have as a concomitant the subjective symptoms characteristic of incipient tuberculosis. It must be borne in mind, however, that in some cases there is hyperresonance, due to vicarious emphysema, hyperfunction, or pulmonary relaxation, as a result of scattered small tubercles which do not exclude all the air from a comparatively large area of lung tissue. Defective motion of the base, so frequent in progressive phthisis, I have not observed all in abortive cases.

Auscultation is more valuable for those who are not adept in light percussion. The inspiratory murmur is the first to be affected—it becomes either rough or interrupted or cogwheel in character, and in many cases there is a prolonged expiratory murmur. Broncho-vesicular breathing is not uncommon, and in some I have heard true bronchial breathing, indicating quite extensive involvement, yet recovery went on speedily, showing that the abortive course may take place even when the lesion is quite extensive. Adventitious sounds are not always heard, excepting in those who have had hemorrhages and in some post-grippal cases. When heard we find on inspiration dry crackles, or crepitations which are often difficult to differentiate from marginal râles and muscular sounds. At one time I thought that friction sounds are a frequent phenomenon in these cases, but I now consider these adventitious sounds as marginal or atelectatic râles, because they are greatly influenced by deep breathing and cough. Of course, to be of significance these objective signs must be strictly localized at one apex and constant for some time.

These are, as was already intimated, the classical symptoms and signs of incipient phthisis and by no means give a clue as to the course the disease is likely to take. In fact, many of the abortive cases are admitted to sanatoria, where they are speedily cured and they contribute no mean portion of the credit claimed by advocates of institutional treatment. In the progressive cases the lesion as well as the subjective symptoms pursue the usual course, and shortly other signs make their appearance. But in the abortive cases the physical signs do not indicate a progression of the disease—the impaired resonance or dullness does not extend lower and lower on the chest, the bronchovesicular breathing does not become true bronchial, tubular or blowing; the dry crackles or crepitation are not superseded by moist subcrepitant râles or gurgles. But in the course of a few weeks, a month or two the adventitious sounds disappear and are superseded by sibilation, and the type of breathing becomes distinctly vesicular in many cases, while in others the

prolonged expiratory murmur remains permanent in the circumscribed area that was affected. While in most cases the local impaired resonance remains, I have observed that in some even this disappears to be replaced by slight hyperresonance, due probably to hyperfunction from relaxation, or localized vicarious emphysema of the lung tissue around the cicatrix, which the healing process has brought about.

Similarly the subjective symptoms are soon abated in abortive cases. The cough, which may have been severe at the beginning, becomes less and less of an annoyance to the patient and ceases altogether within six to ten weeks; the weakness and languor, which persists in progressive cases, is not severe in the abortive and soon the patient feels strong enough to work at his usual occupation. With a good appetite and normal gastric function the patient soon gains in weight and wonders whether the diagnosis of tuberculosis made by the physician was correct. One point has helped me occasionally in cases beginning with hemorrhage: In progressive cases there is usually a history of cough, weakness, night-sweats, etc., for weeks or months before the hemorrhage, while in the abortive type of the disease this is rare—the hemorrhage usually comes without any premonition, and even without any exciting cause.

A reliable diagnosis of abortive tuberculosis can, under the circumstances, not be made immediately upon seeing the case. It is only by following its benign course that we can recognize this special form of tuberculosis. Those without pulmonary hemorrhage can in the vast majority of cases not be diagnosed at all.

Abortive tuberculosis is to be differentiated from collapse induration, an apical lesion first described by Krönig; and also from simple non-tuberculous apical catarrhs which are met with among persons engaged at indoor and dusty occupations, and after attacks of influenza. But this is often very difficult. All these apical lesions have in common most of the subjective and objective symptoms and signs of incipient pulmonary tuberculosis. In many cases only the bacteriological findings, when revealing acid-fast bacilli, can decide. I am usually guided by the following points: Collapse induration is met with only in mouth breathers, while pulmonary tuberculosis occurs in persons with or without nasal obstruction. In collapse induration there is no hemoptysis, excepting such as is derived from the nose, pharynx, or tonsils, while abortive tuberculosis often begins with hemorrhage more or less profuse. The albumin reaction of the sputum is always negative in collapse induration and in simple apical catarrh, and positive in abortive tuberculosis. The subjective symptoms of abortive tuberculosis are more pronounced than in the non-tuberculous apical lesions—anorexia, fever, tachycardia, dyspnea, fatigue, languor, hoarseness, etc., are rare in the latter and common in the former. The physical signs of collapse induration are invariably found in the right apex, while abortive tuberculosis may be implanted in either apex with about equal frequency. The motion of the base is restricted very often in tuberculosis and never in collapse induration or simple apical catarrh. In doubtful cases only the course of the disease, when carefully observed, can decide whether we are dealing with an abortive lesion of pulmonary tuberculosis, or with a simple, non-tuberculous apical lesion, or a usual case of phthisis.

There are many theoretical problems presented by the abortive form of tuberculosis which have some practical bearings. It is a question whether we deal here with patients whose individual resistance to the noxious effects of the tubercle bacilli is so great as to overcome the destructive tendencies of the germ, or perhaps this form of tuberculosis is caused by an attenuated strain or race of microorganisms characterized by low virulence. It is well known that the differences in the severity of epidemics of infectious and contagious diseases, or even of individual cases in the same epidemic, is often due, in part at least, to the varying degree of virulence of the invading germ, even conceding important differences in susceptibility of the invaded hosts. Thus there are known differences in virulence of various strains of diphtheria bacilli, of streptococci and also of the tubercle bacilli which are known to become quite attenuated when grown on artificial media, often losing most of their virulence, even when growing luxuriantly. Cattle infected with attenuated tubercle bacilli suffer less than those infected with virulent strains, as has been shown by many authorities, notably Behring. The wide distribution of such attenuated strains of tubercle bacilli in nature, says Cornet, urges the conclusion that for man also there are tubercle bacilli, be they of the bovine, human, or similar strains, of low virulence and these may, at least in many cases, be the cause of abortive tuberculosis. How far we can enhance the natural resistance of the body, thus preparing the soil for the abortive course in patients who were infected, must be further investigated.

If it could be proven that in abortive cases we are dealing with an attenuated strain of tubercle bacilli it may be of practical importance to study the bacteriology of this type of the disease as well as of other groups of benign tuberculosis in man. That the virulence of the various strains of tubercle bacilli differs to extreme degrees is well known, but I do not know that the study of the problems connected with it has been given the attention it deserves.

It is also of practical importance to inquire whether an individual who passed through an abortive attack of tuberculosis is more or less susceptible to another infection with the tubercle bacilli. Of course it is evident that in cases in which the bacilli remain alive, though inactive, in the lung tissue or in the peribronchial glands, there is always danger of an acute recrudescence of the disease under some exciting cause. We have seen this to be the case with many of those who have a mild attack of tuberculosis, recuperate and several months, perhaps years later, after an attack of typhoid, influenza, or pregnancy, etc., there is a fatal recrudescence of the disease which had been dormant. Experimentally it has been proven that the chalky deposits in healed lesions of tuberculosis harbor virulent tubercle bacilli.[10]

On the other hand, there is evidence to the effect that an infection with tubercle bacilli may immunize against a second infection. Koch has long ago shown that tuberculous guinea-pigs are immune against new infection with tubercle bacilli; Behring also brought forward evidence showing that cattle can be immunized in this manner. Calmette is of the opinion that healed tuberculous lesions, especially of the glands, during childhood, confer immunity against tuberculosis in later life. Römer shows that spontaneous tuberculosis of a chronic character protects guinea-pigs against renewed in-

fection. Among human beings also Römer says, that "the tuberculous are immune against tuberculosis." A slight early tuberculous process protects the individual against mild new infection.[11] If this be true we may expect that those who passed through an attack of abortive tuberculosis and the lesions have healed through cicatrization, not through calcification, are more or less immune against renewed infection by the tubercle bacilli.

## A CONSIDERATION OF THE THERAPEUTICS OF INTESTINAL AUTOINTOXICATION.

By WILLIAM HARVEY KING, M.D.,

NEW YORK.

It has been known for generations there is a certain amount of toxemic absorption from the intestinal tract into the general circulation, but this fact was little understood by the profession and consequently was not taken seriously into account by the physician in his daily practice. More recently, however, there have been many discoveries along these lines, and today the subject is well understood and is one of the most important that confronts the physician. Calomel with its saline cathartic was about the only treatment given, but the modus operandi of its action was little understood.

Symptoms produced by antointoxication are so varied in their character and anatomical distribution that in attempting to describe them one would be carried into a great diversity of conditions. I shall not attempt a description of the symptoms of autointoxication, but I wish to call attention to some symptoms which I believe have been given too much prominence, even being considered as pathognomonic without any foundation. Headache has been considered one of the chief indications of autointoxication. Recently a long article appeared in a well-known medical journal advocating a certain diet as a never-failing cure, the only diagnosis given of the autointoxication being that the patient suffered from headache. But few of the patients I have found suffering from autointoxication complained of headache, and in three of the most severe cases, in which the ethereal sulphates were never below 0.59 gram in the twenty-four hour output, the patients, although above thirty years of age, stated thay had never had a headache. Another indication given as diagnostic of autointoxication is constipation. My own experience covering more than three hundred cases, in which careful laboratory examinations demonstrated a marked autointoxication, has proved that people suffering from constipation have less toxins on an average than those who do not. Alternate constipation and diarrhea is a far more diagnostic symptom. The functional nervous symptoms are many. Not every case of neurasthenia is due to autointoxication as some would make us believe, but I have seen recoveries from neurasthenia after the patient was cured of autointoxication, when many other methods of treatment for the neurasthenia had been tried and failed. One of my patients suffered much on account of her eyes. She had visited many oculists, both in New York and Berlin. The close application of her eyes for only a few minutes would cause the greatest distress. All the physicians she consulted practically agreed that they could find nothing very materially wrong with her eyes, the weakness being due to a condition more general than local. They had changed the glasses and trained the ocular muscles without effect. I treated her for autointoxication without any thought of her eyes. To my surprise they began to improve at once, and five months after discontinuing the treatment she was reading and sewing for long periods at a time without suffering. Sleeplessness is a marked symptom in some cases, as evidenced by the disappearance of the insomnia after relief of the autointoxication. Sleeplessness, however, is by no means a universal symptom for many complain of a constant drowsiness with heavy unrefreshing sleep. Many persistant skin symptoms disappear after the relief of autointoxication. These few instances show how widely different conditions may depend on autointoxication.

The putrefaction I refer to in this paper is due to the anaerobic bacilli, the presence of which in the intestines is caused by the absence of oxygen which has been consumed by the colon bacilli. There is putrefaction, with a correspondingly large gas volume, always above 50 per cent. and generally ranging from 90 to 130 per cent. Indol is present in a much more than normal amount, and skatol to a marked degree, the latter sometimes in such abundance as to give the peculiar odor of skatol to the entire fecal mass. Indican is present in large quantities in the urine, but as it varies so markedly with the different degrees of concentration, as well as at different times of the day, it is not a safe guide for close observation. If one examine the urine for indican, beginning with a specimen voided by the patient on first rising and then examined every two hours until bedtime, one will find indican more pronounced in the morning, and gradually decreasing until evening, when it may begin to slightly increase again. This variation, irrespective of the specific gravity, shows that the absorption of toxins is greater during the night. A quantitative sulphoether test of a twenty-four hour specimen of urine is the most reliable, as it gives the amount of absorption into the system and it is this absorption that is so injurious.

The sulpho-ethers taken in connection with the fecal test give an indication as to the location of the putrefaction, the absorbing power of the small intestines being much greater than that of the large intestine. The citation of two cases will illustrate this point. One gave in a fecal examination a gas volume of 103 per cent. with a correspondingly large amount of indol and skatol, while the urinary examination gave only 0.30 gram of the sulpho-ethers.

In the other case, a fecal test showed a gas volume of 60 per cent., a moderate amount of indol and a slight trace of skatol, yet the urine showed 0.70 grams of the sulpho-ethers passed in twenty-four hours. In this latter case the location of the putrefaction was undoubtedly high up, probably in the small intestines. This proportional increase in the sulpho-ethers, owing to the high location of the putrefaction, is always in the indoxyl potassium sulphates. According to my experience, when the putrefaction is in the large intestine, as evidenced by the small proportional amount of the sulpho-ethers, the indoxyl potassium sulphates furnish about seven hundred parts to the thousand of the combined sulpho-ethers, while in those cases in which the putrefaction is located in the small intestines the indoxyl potassium sulphates furnish approximately nine hundred parts to the thousand. I believe this distinction is very important as an indication in the treatment, for when the putrefaction is located in the small intestines much may be accomplished with internal medication. It is in this condition that the lacto-bacillus of Metchnikoff is of the greatest use if the treatment is properly carried out. I have, however, tried all the internal medicinal forms of treatment that have been in vogue during the last few years, when the putrefaction was located entirely in the lower intestine, with very indifferent results.

The internal treatment may be divided into two general classes: intestinal antisepsis, and the lactic bacillary treatment of Metchnikoff. Of the former, I have used the various preparations, as they have appeared from time to time, which it was claimed would survive the digestive powers of the stomach and duodenum. I have employed these separately, and in connection with medication which was supposed to increase the secretion of bile, thus assisting the antiseptic property of the agent. These remedies have been tried along strictly scientific lines, in connection with a laboratory where the fecal mass was carefully examined, and always taken in connecton with the sulpho-ether test of the urine. Benefits from these so-called antiseptic remedies have been about in proportion to the cathartic action of the remedy employed. The thorough washing out of the lower intestine will for a few hours reduce the putrefactive condition, as well as the toxins in the urine. That this condition remains for a few days only is proved by the gas volume arising immediately again to above 50 per cent. and the toxins as quickly reappearing in the urine. I have made a careful study of the comparative value of the different cathartic remedies in removing the toxins. I find the action of the saline cathartics is but slight in this respect, and gives only temporary relief, that cascara scarcely affects them at all, but that a full dose of castor oil quite thoroughly removes them for the time being. When the saline cathartic is preceded by a dose of calomel the effect is marked, but only for three or four days. This is undoubtedly due to the antiseptic quality of the bile which is increased by the calomel.

These statements regarding intestinal antisepsis are not based on one or two instances, but on a great many, always corroborated by laboratory analysis. If there is today an antiseptic which can be given by mouth, and reach the point in the large intestine where its action is needed, and be of any material use, I have been unable to discover it. That bile is a powerful antiseptic in this condition is proven, for in the crisis which often occur in these cases when the increased flow of bile is paramount, the sulpho-ethers begin to decrease even before the purging begins and entirely disappear soon after, but when a cathartic is used which does not increase the flow of bile, the sulpho-ethers increase for the first twenty-four hours and then decrease for twenty-four hours, when they begin to gradually work back to their original level.

I have employed the Metchnikoff bacillary treatment in every form, having used the various milk preparations, also many preparations of the bacillary tablets. I believe I have tried all the different American products as well as those of European manufacture. In those cases in which I have prescribed a bacillary milk diet only, cutting off all other food, the putrefaction has disappeared, the gas volume being reduced to a minimum. The patient will ordinarily thrive well for a few days, perhaps for a week or more on this diet, but his strength will then rapidly decrease, and it has been impossible to maintain a working energy on it for a great length of time. I am satisfied, however, that occasional periods of diet of this kind may be beneficial in some cases. If the bacillary tablets are fresh they have a certain beneficial action, but that this action is limited when the colon is the seat of the putrefaction is proven by laboratory analysis of the feces and urine, as well as by failure to remove the clinical symptoms. It has been sufficiently proven in my cases that the lactic bacilli in this form have a limited action in destroying Welch's bacillus and lessening putrefaction, but that they have very little if any action in destroying the Shiga or diarrhea bacillus. It is for the destruction of this special bacillus that the milk preparations surpass the dry forms. The limited action I refer to in the reduction of putrefaction is the lessening of gas volume, as well as the indol and skatol. The bowels will be slightly more regular, and other symptoms attributable to putrefaction may be relieved to a certain degree, but the action is not sufficiently powerful to eradicate the condition when it is confined entirely to the lower bowel. Somewhat different has been my experience when the putrefaction is in the small intestines, as evidenced by the sulpho-ethers in the urine being out of all proportion to the condition found in the stool. Here it is that medication will be found most useful and the lactic bacilli of the greatest benefit. The method and thoroughness of administration are most important. When given on an empty stomach the efficiency of the lactic acid bacilli is much greater than when given after meals, but they are liable to produce disturbance of the digestion. When administered after meals it is claimed the bacilli aid digestion, but that their effect in overcoming the putrefaction is lessened is proven by the following case. The fecal examination in this case before treatment showed 96 per cent. putrefactive gas volume, with a large amount of indol and skatol, and urine examination showed 0.70 gram of sulpho-ethers. The patient was placed on the dry bacillary treatment, two tablets one half hour before meals. After four weeks of such treatment the examination of the feces and urine showed gas volume 21 per cent., trace of indol, no skatol, and sulpho-ethers 0.18 gram. The tablets were now given immediately following the meals. After four weeks of this treatment, examination showed gas volume 110 per cent., with a return of the indol and skatol, and sulpho-ethers 0.91 gram. Reverting to the original form of administration the former good results were obtained. I could cite at least five similar cases.

It would appear from this that the claim that dry bacilli given after meals are just as effective as when given on an empty stomach is not true, but they even make matters worse by interfering with digestion. The most effective method I have found of administering the bacillary milk is to give it with the breakfast. The meal should consist of some kind of cereal, preferably rice or the malted foods, plenty of milk and sugar, a cup of cocoa made with milk, and a couple of slices of bread. With this breakfast there are given about eight ounces of bacillary milk. We here not only get the effects of the bacilli taken in the preparation itself, but the sugar furnishes a fermenting medium to convert the milk taken with the cocoa and cereal, which I believe prolongs the action for a greater period than when taken in the ordinary way. This has been my most successful method of administering either the milk or dry preparations.

I consider the breakfast as given above a very essential feature of diet. The way the food is eaten is also very important. There is no condition in which eating slowly and chewing the food thoroughly has a more beneficial action than in autointoxication. Very little fluid, not more than four or five ounces, should be taken with either the lunch or dinner, but plenty of water should be drunk between meals. I believe it is better in most cases to confine the diet to meat once a day. Yet I must admit I have found no great reduction in the putrefaction by cutting out meat, as evidenced on examination of the feces and urine. Veal and pork should be taken very abstemiously. Whether canned meats or fish are bad in this condition I cannot say as I have had no experience with them. I believe fresh white bread produces more intestinal putrefaction than any other article of diet. If one will take the trouble to make proper laboratory examinations, when one is eating a quantity of fresh white bread and when the patient is eating a limited amount of starch treated bread, such as is used for diabetes, one will be surprised at the great decrease of putrefaction with the latter. Eggs disagree with some people and in such cases should be avoided, but when they are acceptable they may be eaten prepared in any way except hard boiled or fried. I have been unable to discover that one kind of vegetable produces more putrefaction than another. I believe the patient is much better off without beer, wine, or spirits of any kind. Beer markedly increased putrefaction in every case I have observed. The sulpho-ethers and the putrefactive constituents in feces increase more from beer than from any other article of food and drink I have observed. Milk as a rule in large quantities is not tolerated by people suffering from autointoxication. Cream or other fats are not well borne. Cake and pastries should also be avoided.

It is my purpose to give a special form of local treatment for the eradication of this putrefactive condition when located within the large intestine, an eradication which has been found to be more or less permanent in its action, according to the thoroughness of the treatment, and the subsequent care of the patient's diet and hygiene. Starting with the premises that the colon bacilli feed on oxygen, that the putrefactive bacilli are destroyed by this same agent, and that the former must utilize all the available oxygen in the intestine before the latter can materially manifest themselves, I sought some method by which I could thoroughly oxidize, not only the surface of the lining of the large intestine, but also carry this oxidation within the glandular cells and tissues of the membrane. The technique of the treatment should be carefully followed, as it is only by exercising great care in this respect that success will be attained. I first give a high enema to empty the bowel of fecal matter, so that the antiseptic afterward employed will not be utilized solely in destroying this dead matter, as well as to clear the membrane that the action may be unimpeded upon its surface, and thus enable a better osmosis or anaphoresis to take place. A colon rectal tube is employed. In introducing it care should be exercised not to allow it to double up, as in a majority of these cases there is a capacious rectum which readily permits it to do so. The tube should be well lubricated so that it will not impinge upon the sphincter, as its easy passage through this muscle is necessary in determining whether it is progressing straight up the bowel. After it has passed the sphincter for an inch or more, the movement onward should be made by easy stages, not more than an inch or two at a time, and made with a delicate touch. If the tube is well lubricated, and the sphincter is not unduly tight, as soon as it begins to double up owing to obstruction, its elasticity is sufficient to force it back when pressure is relaxed. Rolling the tube slightly may change the position of the point so that it will pass an obstruction. Allowing the fluid to flow will also have a tendency to clear away a slight obstacle, as well as stiffen the tube. The next point is the slow and careful introduction of the water. The bag is placed but little higher than the body of the patient. The water should flow very slowly to prevent a sudden damming up at the end of the tube, but be allowed to work its way back beyond the fecal mass, and at the same time to soften and percolate through it. For this preliminary injection I use only plain water. If possible the patient should rest for a few minutes before going to the closet, where the bowel is thoroughly emptied. The patient is again placed in position and the tube is reintroduced. With this second injection an electric current is employed. A large electrode, which thoroughly covers the abdomen, is placed directly over the line of the transverse colon. To this is attached the positive pole of a continuous current. The other rheophore is attached to an instrument by means of which the current is made to traverse the fluid injected, thus making it the negative pole. One word regarding this instrument. I formerly used a rectal electrode I invented a number of years ago, which I believe was the first electrode used for hydroelectric application, and as it has been before the profession for so many years it need not be described here. This electrode, however, was capable of being introduced into the rectum for the distance only of a few inches. I therefore devised an electrode for the treatment I am about to describe, which also serves as a connection between the leader of the syringe and the colon tube. This consists of a piece of hard rubber tubing, having the usual corrugated ends for the attachment of the rubber tubes, with a sufficiently large opening to allow the fluid to pass freely. In this opening is placed a piece of platinum wire soldered to an ordinary split tip connection which leads up through the side, and to which the rheophore is attached. This instrument is left in permanent connection and serves the purpose of conducting the fluid and the electrification of it admirably well. For this second injection a normal salt solution is used, to which are added two ounces of fresh electrozone per quart of water. There is undoubtedly a certain amount of

chlorine also set free by the passage of the electric current through the normal salt solution. As chlorine is strongly anaphoretic in its electrochemical affinity, we not only get its action upon the surface of the membrane of the intestine, but also carry it within the glands and follicles of the membrane itself, and it is here that its action is most needed. The action of chlorine in this connection is too well understood to call for elaboration here. I may mention, however, that the chemical affinity of hydrogen for chlorine is so much greater than it is for oxygen, that the $H_2O$ is split up, leaving a free oxygen. As stated in the first part of this paper, anaërobic bacilli cannot thrive in the presence of oxygen, and the formation of the different groups of the anaërobic bacilli is because the colon bacilli have first consumed all the available oxygen. The oxygen thus set free in this treatment not only destroys the entire group of anaërobic bacilli, including Welch's bacillus which causes the putrefaction, but it also destroys the medium on which it thrives, and at the same time furnishes food for the normal bacilli, thereby building up a strong family of the normal group.

In properly selected cases I have never seen such positive results as this treatment produces. The number of treatments required varies as to the condition of the patient. In most cases from eight to twenty treatments given daily will suffice. The indican and sulpho-ethers gradually disappear from the urine. The skatol disappears from the feces, the indol is decreased, and the gas volume is reduced to from 12 to 18 per cent. The clinical results are manifest by the disappearance of the insomnia and other conditions depending upon the autointoxication.

I wish to say in conclusion that the laboratory analysis in all these cases have been made by Drs. William McKimmie Higgins and J. J. Connellen.

64 West Fifty-First Street.

## BLUNDERS MADE BY NATURE.

### THE PART PLAYED BY NATURE IN CAUSING DISEASE OF THE GENITOURINARY ORGANS AND THE SKELETON.

By AUGUSTUS MAVERICK, M.D.,

SAN ANTONIO, TEXAS.

### Genitourinary Organs.

In his book, "The Nature of Man," Metchnikoff[1] mentions several natural disharmonies in connection with the sexual organs. He draws attention to the uselessness of the hymen. Placed as a screen before the entrance to the vagina of virgin women it not only serves no useful purpose but sometimes acts as an impediment to the free outflow of the menstrual blood, causing the woman much suffering and allowing bacteria to grow in the stagnated blood clots and retained secretions. The first step in married life is to break the hymen and this may cause so much pain to the woman that she may fear and repulse her marital duties for a long time afterward. The husband on account of the hymen sometimes experiences such great difficulty during the first days or weeks of marriage that this initial sting of discontent may remain as a permanent scar upon his married life—for as much as he may fool himself in not believing it the sexual item is the most important in his marriage if he marries for love. In certain savage tribes it is the duty of the high priest to break the hymen of all brides before turning them over to their husbands, but in our race we do not place the same confidence in the presiding marriage official and prefer to take care of our own troubles from the beginning.

As useless as the hymen in the female is the prepuce in the male. Here is a worthless flap of skin which tends to collect dirt and decomposing secretions and predisposes the individual to venereal disease. Sometimes it is so tight that upon working back it constricts the urethra and hinders the passage of urine. Of the many excellent hygienic rules which Moses handed down to the Jews circumcision of all male infants is one of the best. The only disadvantage claimed against excision of the prepuce is that it lessens the sexual power, but judging from our Hebrew friends this is by no means the case.

Menstruation is one of the crudities of nature which we could readily dispense with and very willingly. "Menstruation," says Matthews Duncan, "is like the red flag outside an auction sale; it shows that something is going on inside." What goes on inside is not only a profuse flow of blood from the over-distended uterine vessels but more or less complete shedding of the inner lining of the womb which must renew itself after each menstrual period.[2] This natural loss of blood each month may act as a drain on weak and ill women which makes their condition steadily worse. There is also usually more or less general illness associated with menstruation—often headache, backache, pimples on the skin, nervousness and depression, and neuralgic pains. In some women there is an exaggeration of these purely natural symptoms, forcing them to bed in agony one week out of every four.

The uterus, as we know, often shifts from its original position, causing trouble by pressing upon the rectum or bladder or sensitive nerve trunks or kinking its neck so that the menstrual blood can only escape under difficulty and with great pain to the woman. The ease with which this displacement takes place is entirely due to insufficient natural support. The uterine ligaments are merely guy ropes which allow the uterus to swing in almost any direction. There is an advantage in this free movement when the uterus becomes pregnant, but it is unsuited for the erect posture of man. Falling of the uterus is also quite common and due to the same cause. Once this organ has become parallel to the vagina there is little to keep it from passing down. Nature's failure to fully develop certain parts of the body at birth is sometimes illustrated in the uterus. Thus the uterus may be double, its interior may be separated by a partition, or it may take other strange shapes which tend to interfere with its function.

In the vicinity of the ovary there are several little remnants of embryonic life and lower animal days, which serve no purpose. The significance of these in the production of disease is that they not rarely become the seat of different kinds of cysts and tumors.

In the male a testicle sometimes fails to pass all the way down to the scrotum but remains in the groin as a sensitive lump causing much discomfort and usually necessitating surgical removal. It would have been much better for us if the testicles had remained altogether in the abdomen and had a place prepared for them there. Situated in the position nature has given them these important and very sensitive little bodies are far too easily injured. The cremaster muscle is intended for drawing the

testicle up out of harm's way, but in man it is entirely too weak for the purpose. The prostate gland in later life has a natural tendency to grow larger, possibly to compensate for the declining sexual power of old age. One-third to one-half of all men over sixty show this hypertrophy of the prostate.[3] If some isolated organ like the testicle cared to enlarge naturally it would excite little inconvenience but the prostate encircling as it does the first part of the urethra causes compression of this tube by its enlargement and dams the urine back in the bladder. Partial or complete suppression of urine is the result unless the gland is surgically removed.

Falling of the kidney from its original position is quite common in women and occasionally causes much distress. Like many other organs the support of the kidney is not entirely suited for the erect position of man. A simple pad of fat plays a large part in keeping it in place, and when the fat wastes away as it is apt to do after childbirth or general emaciation from any cause the kidney passes down like a wedge and gains its freedom. Tight lacing sometimes aids the natural conspiracy. The kidneys have the reputation of being great filters, but we are quickly finding out that they are not perfect by any means. Formerly when the kidneys allowed a little of the albumin in the blood to filter through into the urine we thought they were diseased, but now we know that perfectly healthy kidneys often allow albumin to pass with merely such slight encouragement as a cold bath, a hearty meal, or muscular exercise.

The ease with which pregnancy is prevented has become one of the pleasantries of the family fireside. Some savage tribes are said not to realize any connection between coitus and childbearing, and this is probably the natural way of looking at it, for when nature built the sexual organs it never expected that we would ever trace the spermatozoon to its lair or follow the ovum in its flirtations down the Fallopian tube. As different writers have pointed out, the fertilization of human ova is much inferior to the system of fertilization in plant life. There is an enormous waste of ova and spermatazoa during the life of each individual, for it is usually a thousand to one shot that nature will miss the spot and it must use plenty of bullets to make up for its lack of skill.

Numerous pseudoscientific writers, especially in Germany, have written a metropolitan library full of volumes concerning the discord which often arises in married life from natural causes. This literature often makes interesting reading but has little or no practical value because the writers look at the subject from a purely selfish standpoint. They think nature is at fault because it does not cater to their private tastes, forgetting that what may be agreeable to us may be injurious to nature itself. If we are to find fault with nature we must do so on nature's own ground without consideration of our own selfish ends. Thus we might say that nature blundered when it allowed so many bacteria to nag at us; but we cannot do this because the bacteria serve nature's end to keep thinning out other forms of life; likewise while the bacteria are troublesome to us we must not forget the bacteria's own point of view, since they occupy just as important a place on the scale of living things as we do ourselves. In nature's eyes we are no more important than the bacteria, in our own eyes we are the rulers of the universe and all living things were made especially for our benefit. We are inferior to bacteria in one thing at least, namely, modesty. If we wish to pick fault with nature, therefore, we must consider nature's advantage in the matter rather than our own. Thus when nature takes every precaution to protect our brain from injury and infection from without and then carelessly leaves little holes in the roof of the nasal cavity for the virus of meningitis and infantile paralysis readily to enter the skull, we may fairly say that nature blundered, not because we die or remain paralyzed, but because nature defeats her own efforts to protect the brain. It is in this way, therefore, that writers on the incongruities of sexual life lose their bearing.

In spite of themselves, however, they occasionally hit the right spot. They truthfully point out the disadvantages of the various sexual functions' failing to develop at the same period. Thus a girl is apparently ready for childbearing at the age of puberty but as we all know the sexual instinct comes several years in advance of the proper development of the childbearing organs, so that to follow nature's signal of beginning womanhood would be detrimental to the health of the young girl and to the life of the child. The spermatazoa commonly becomes active before the boy is sexually capable and they may remain so long after the old man has become impotent. The sexual desire may persist for some time after the testicles or ovaries have been destroyed by disease or surgically removed causing considerable nervous disturbance. Nervous symptoms connected with the beginning and end of sexual life in women are purely natural, but as we know they sometimes make the woman a nervous wreck for the time being and may even encourage an outbreak of insanity. The unhappiness to married life which so often arises because of a difference of sexual feeling between man and wife is frequently pointed out as an unnecessary burden placed on us by nature, but we can hardly find fault with nature for this. Nature believes strictly in polygamy and expects us to mate as often as it is necessary to find perfect harmony. To act naturally means to perform rape and adultery and run a harem; if we live unhappily because we do not act naturally we have our own taste to blame and not those of a lascivious and unchristian nature.

### The Skeleton.

When nature allowed man to take the erect posture there were many anatomical structures about the body which were altogether unsuited for the change of position. During the thousands of years that followed, most of these were remedied by nature in its slow and often incomplete way, but not a few remain with us today as glaring examples of nature's lack of enterprise. One of the most conspicuous of these is the arch of the foot. At least one-third, some say one-half, of all adults today have arches too weak to support their weight with more or less flatfoot as a result. Forty per cent. of all applicants rejected by the United States Army fail because they have flatfoot, and these applicants are young men in the prime of life.[4] The ligaments of the arch are in the first place too weak to keep it from flattening out, and as the arch yields the bones of the foot atrophy from pressure; the insertions of the leg muscles beneath the foot are called upon to support the falling arch, but they were not originally arranged for this purpose and their attachments are not suitable to lend much aid. Overde-

veloped leg muscles may compensate to a certain extent for weakening arch ligaments but as a general rule the larger and more robust an individual, the more his arches suffer from the additional weight. Some races like the Arabs are lucky in having naturally high arches while others, especially negroes, have very low ones. Shoes have nothing to do with the cause, for a shoe with a heel really supports the arch. Much of the trouble is due to the fact that the foot is not placed at right angles to the leg as it should be for walking and standing purposes and really needs a little support under the heel to tilt it forward. To stand around barefooted in the natural way will encourage flatfoot quicker than anything else as is so well illustrated among sailors and washerwomen. The suffering and hindrance to standing which flatfoot causes is too well known to need discussion.

Above the first rib in the neck another one sometimes arises on each side and is called the cervical rib. It plays no part in the formation of the chest and is entirely a useless structure. In most cases it remains merely useless but sometimes it is long enough to get in the way of the nerve trunks and vessels of the neck and produce much mischief. Its pressure on a vessel may cause aneurysm or thrombosis; upon a nerve trunk, persistent neuralgic pains, muscular atrophy, or interference with respiration.[5] As pointed out in a previous article[6] a series of little ribs properly arranged around the neck with a plate of bone in front would do much to lessen the frequency of injuries to the windpipe, the large neck vessels and nerves, and the ease with which the neck is broken. An extra upper rib is less frequent than an extra one below; in fact there is a natural tendency for the upper part of the chest to degenerate in order to shorten the trunk and, as before mentioned,[6] this degeneration affecting the lung apex helps predispose this part to tuberculosis. Extra lower ribs are also of course useless supplements, but they are in a good place not to produce harm by interfering with important structures. The lower ribs in the normal thorax could readily be dispensed with since they give little or no protection to internal organs and are useful only for the insertion of such rudimentary muscles as the serratus posticus inferior and part of the latissimus dorsi.

In a previous article[7] the natural tendency of the lower part of the spinal cord to degenerate and how this weakened this part to the virus of locomotor ataxia was also mentioned. There is a lot of useless space lost in the lower part of the vertebral column; the cavity of the spine runs down into the sacrum but the spinal cord itself ends in the lower thoracic vertebræ and only a little strand of nerve fibers runs on toward the end of the passage. This is not due to the tendency of the spinal cord in man to degenerate and allow the brain to do all the heavy work, for the same is found in lower animals and it is said that in such a low animal as the hedgehog the cord ends far up in the anterior thoracic region. The os coccyx representing all we have left of a tail is, of course, vestigial. It sometimes becomes broken during childbirth from sticking itself in the way of human progress and causes quite a little pain afterward, but otherwise it never bothers us by its presence. The wearing of tails is no longer considered fashionable, but that we did once have tails and are prepared to grow them again should the fashion change is shown by remains in our pelvis of tail-wagging muscles now rudimentary and degenerative from lack of use. Wiederscheim[8] divides these muscles into two groups; the ventral, made of the coccygeus and curvator coccygeus, and the dorsal, consisting of the extensor and levator coccygeus, in addition to which is sometimes present the caudofemoralis which flexes and abducts the tail when the thigh is fixed. Wiederscheim also calls attention to the remains of arteries and veins which formally nourished the tail; how the continuation of the abdominal aorta is sometimes represented by a variable weak vestigial vessel, the arteria sacralis media, a duplicate of the caudal artery in some long tail animals. Even today we very rarely hear of a child being born with a tail and there is a picture of one in Gould and Pyle's "Anomalies and Curiosities of Medicine."[9] These modern tails, however, are too short for any use, unless it is to make the father stop drinking.

The skeleton shows many variations in its more intimate anatomy. These make little difference about the trunk and limbs, where the bones are for the most part large and clumsy anyway, but in the face slight changes from the original may be the cause of much trouble. A good example is seen in the frequent tendency of the bony palate to arch too far upwards causing irregularities of the teeth, deflection of the nasal septum, and mouth breathing. The retraction of the jaw in higher races has been a factor in the production of irregularities of the teeth so common among us. Occasionally a natural reversion is seen among our race in which the jaw becomes unduly prominent again, causing the lower row of teeth to stick out beyond the upper row, making perfect chewing impossible.[10] Sometimes there is a natural bending inward of the tip of the shoulder blade causing persistent shoulder pain of obscure origin.[11]

The phalanges of the fifth and less conspicuously of the third and fourth toes are well known to be vestigial, no longer of use and showing a degenerative tendency. This would readily explain the commonness of corns on the little toe. Corns are, of course, caused by shoes, but if nature had not allowed the little toe to degenerate corns would be much rarer, even though we were foolish enough to squeeze a number eight foot in a number seven slipper.

# THE COMPULSORY DETENTION OF THE HOMELESS TUBERCULOUS.*

By EGBERT GUERNSEY RANKIN, M.A., M.D.

NEW YORK.

At the autumn meeting of this society in 1904, I had the honor of presenting a paper in which the above measure was suggested. To-day I will again, with your permission, present the same subject, but in a more definite and positive manner; and at the same time I will endeavor to show sufficient grounds for a stricter application of a law which, if effectively applied, would eliminate one of the most potent sources of the spread of tuberculosis.

It is not generally known that in the City of New York the Department of Health, Sanitary Code, Section No. 139, has the power to detain forcibly homeless, positive cases of tuberculosis. Instead of discussing the application of this law—or rather as matters now stand, its nonapplication—let me state a few conditions which bear upon the situation.

There is no disease which calls for classification and segregation according to social conditions to such a degree as tuberculosis. This is obvious from its very nature, especially from its manifestly greater prevalence among the lower classes. New York has its numerous so-called "lung blocks," and they are located just where one would expect to find them, namely, where the crowded tenements prevail, specially those inhabited by peasants of Eastern Europe and of Sicily, and Jews of a low class.

To designate the mode of living of this type as unhygienic is almost an euphemism to cover harsher words. Joined to squalid surroundings, there is ignorance and indifference to anything better. Cleanliness is not attainable, and if it were, often would not be appreciated.

The tuberculous patient who is well placed in life generally, if not always, seeks restoration in some well-appointed sanatorium and is not a menace to the community. Those of slender means, or none, such as clerks, salesmen, and others of this class, are usually cared for by friends or find refuge in some semi-charitable institution; they, likewise, are not a menace to the public health, for they cannot be regarded as belonging to the class I have in mind, and their habits of living are not such as to constitute them a source of danger.

The class to which I refer is composed of those unfortunates who either have no settled abiding place, or who live in lodging houses of the poorest type, or are members of a family living in a crowded, dark, and unclean tenement apartment. Many of these persons have been laborers of various kinds, workers in the street excavations, sweatshop workers, etc., some of them tramps, some of them "hospital rounders," and most of them enter a hospital in an advanced stage of disease, having refrained from seeking relief until general weakness compelled them to do so. Many of this class, again, are alcoholics. Some go to one tuberculosis hospital for a while, then to another, then out again; then into a hospital once more, then out for a while, and so on, as long as they can continue. This is a matter of record in the Bureau of Dependent Adults of the Department of Public Charities of the City of New York. These are the "rounders." In the intervals of their sojourn in the city does any one suppose that these persons are careful about their sputa? They belong to that large class of public spitters which in New York is allowed by the police to violate the law with the utmost impunity.

I am speaking as the result of experience in the Tuberculosis Division of the Metropolitan Hospital, with its 904 beds. This institution, as is well known, is for the poorest class. While the vast proportion who enter it are in a more or less advanced stage of disease, some so far advanced that they simply come to find a place in which to die, a large majority are ambulatory cases, many of which improve. It is this class which constitutes the chief source of danger.

A daily experience in the Metropolitan Hospital Tuberculosis Division is as follows: A patient applies for discharge, perhaps one of the physically better types, having improved (I am glad to be able to say that many do improve), or a patient desires to leave who has not improved—simply wishes to return to the city. The reason often given is a desire to seek employment, which is genuine in some cases, but in others is sometimes a craving for an alcoholic debauch. In all instances the patients present more or less pronounced evidences of tuberculosis, the majority with abundant bacilli in the sputum. They will be told that they are not in condition to leave, that if they do go it would be dangerous or even fatal, that they will come back much worse, etc.; but no, they will go.

Does any one suppose that persons of this type heed the cards of instructions which are given to everyone on leaving the hospital, which briefly state how to take care of tuberculosis and how to avoid giving it to others? These cards or leaflets are printed in several languages, and in the Yiddish dialect.

Let me cite a case for the sake of illustration. The patient, a fairly intelligent Irish laborer, about fifty years of age, after six months in the hospital, during which time he improved considerably, applied for discharge. Notwithstanding improvement, there were abundant bacilli in the sputum and marked evidences of tuberculous disease in both lungs. He was informed that it would be harmful for him to go out unless he had a home. He had none, but said that he wanted to go to work. After about three weeks he returned, having lost all that he had gained. On being asked what he did, he replied that he had two dollars, and as long as that lasted he slept in lodging houses; after that, in the park squares, the weather being mild. A case like this has a two-fold aspect; it not only is a source of spreading the disease, but the possible chances of recovering are thrown away, which is perhaps the lesser of the evils.

The Tuberculosis Infirmary makes it a rule to notify the Department of Health three days before the discharge of patients. This rule, I believe, has been followed by all the other tuberculosis hospitals in the Department of Public Charities of the City of New York. During this period the home of the patient is investigated by the Health Department to ascertain if it is suitable for the care of the patient. This department, however, only visits regular bona fide residences, not lodging houses. According to the report published last year it had 159 nurses engaged in tracing these patients, and 21,700 visits of this nature were made in 1911. It also sends nurses to visit the homes of tubercu-

*Read at the meeting of the New York State Homœopathic Medical Society, Albany, February 11, 1913.

lous patients to give instruction as to care, and to exercise a general supervision. In 1911, 231,183 visits of all kinds were made. All most excellent as far as it goes; but let us look further.

First, let me call attention to the fact that the Department of Health visits only alleged bona fide home addresses; lodging houses are not visited. According to the Metropolitan Hospital statistics this leaves about 40 per cent. (namely, 328) of the infirmary male patients without any surveillance from the Department of Health after discharge. Some register from lodging houses so as to escape this department.

Again, during the calendar year 1911, there were admitted to the tuberculosis hospitals of the City of New York 15,145 persons. Of this number it was estimated that 3,786 were readmissions, leaving the number of individual cases 11,359. Of this number 6,122—a percentage of 54—were classified as homeless. This is according to the report of Mr. F. S. Mann, secretary of the committee on tuberculosis of the Charity Organization Society.

The Department of Health report shows that on December 31, 1911, there were 32,635 cases of tuberculosis on its register. The total number of different registered cases for the year 1911 is 55,121, though the actual number on the register at any one time is about 32,000. For the year the number not found at the addresses given is stated to be 7,454. In regard to these cases the Health Department says: "They may be grouped under four heads: (a) Patients giving false addresses; (b) Patients giving correct addresses when reported by a hospital, but failing to return to that address upon discharge; (c) Cases moving in the interval between nurses' visits at the addresses given and leaving no address; (d) Cases which reside at the addresses given, but which the nurse cannot find. Often the patients are boarders in a family, the name of which is not given."

It will thus be seen that there is a very large number of tuberculosis sufferers of an irresponsible class, wandering at will, as it were, throughout the city, upon whom there is absolutely no restraint.

In 1911 the number of cases forcibly detained by the Health Department was 54; in 1912 it was 73—a contrast to the number reported as homeless. The Riverside Hospital has a capacity of 160. In this institution there are two new buildings approaching completion, with an additional capacity of 160 (80 each), making a total of 320. Another Department of Health Tuberculosis Hospital, that at Otisville, is for the better class of cases only. In the year 1911 there were admitted to the tuberculosis institutions of New York, not including sanatoria, 11,309 persons, not counting readmissions; of this number 3,359 died in these institutions, leaving that much room for new admissions, but leaving a total of 8,000 to be cared for.*

The present number of tuberculosis beds in New York is 2,635, and about 1,000 more will be added as soon as Sea View Hospital on Staten Island is opened, making a total of 3,635. With over 30,000 registered cases, of which at least over 6,000 are apparently homeless, it is obvious but a small portion could be detained; therefore, the need of a still greater number of beds for tuberculosis is manifest. This number necessarily varies according to different observers; about 7,000 is the figure usually given. The Hon. Homer Folks says that for the State outside the city the number of tuberculosis beds should stand in relation to the number of deaths from tuberculosis in the proportion of two to three, two beds to three deaths; and in the city there should be as many beds as deaths, so according to the number of deaths from tuberculosis in the city in 1911 (10,248) there should have been 10,248 beds, according to this estimate.

It is obvious that under present conditions an effective solution of this problem of caring for the homeless tuberculosis population is impossible. What should be done, however, is plain; namely, an increase of hospital accommodation should be provided, and Riverside Hospital should be made exclusively a place of detention.

The situation may seem hopeless, but it is not so. Something has been accomplished, for in 1905 the death rate from all tuberculous diseases was 2.40, and in 1911 it was 2.20. In the instance of pulmonary tuberculosis the decline was greater, being in 1905, 2.12, and in 1911, 1.76. It should be taken into consideration that during recent years there has been an enormous influx of foreigners into New York of a low type. One has but to observe the streets to note this unwelcome fact. Many of these people represent generations of poverty and bad hygienic conditions, as evidenced in their physiognomies and physique, and they naturally more readily fall victims to tuberculosis. In other words, tuberculosis has decreased, notwithstanding the fact that the class from which it chiefly recruits its ranks has increased.

The number of homeless tuberculosis patients herein given, namely, 6,122, may be too large, for it is difficult to be accurate when computing the number of persons who have no settled homes and whose addresses are sometimes fictitious. However that may be, the fact remains that whatever may be the exact figure there is a large number of persons with tuberculosis in New York upon whom no restraint or surveillance is possible as matters now stand. Why should they be allowed to spread their infection?

226 Central Park, South.

*Report of Mr. F. S. Mann, Secretary Committee on Tuberculosis, Charity Organization Society.

## TUBERCULIDES.

By WILLIAM P. CUNNINGHAM, M.D.,

NEW YORK.

CLINICAL LECTURER ON DERMATOLOGY AT FORDHAM UNIVERSITY, ASSISTANT PHYSICIAN DERMATOLOGICAL DEPARTMENT HARLEM HOSPITAL, CLINICAL ASSISTANT NEW YORK SKIN AND CANCER HOSPITAL.

In attempting to define a tuberculide I am reminded of the banal witticism of our childhood days, to wit, "When is a door not a door? When it is ajar." When is a tuberculosis cutis not a tuberculosis cutis? When it is a tuberculide.

A tuberculide is a disease of the skin, in some unproven and uncertain manner, indirectly and circumferentially, connected with tuberculosis. It is like tuberculosis; but it is not tuberculosis. All this is delightfully vague. The elucidation runs something as follows: In true tuberculosis cutis the bacillus is demonstrable. In a tuberculide it is not. But the tuberculide often occurs in association with tuberculosis elsewhere, and it is assumed that the toxins of the bacillus are responsible for its production. In other words it is a by-product and not a direct product of the bacillus. Examples of

true tuberculosis of the skin are found in lupus vulgaris, tuberculosis verrucosa cutis (really a warty lupus sometimes called lupus verrucosus), verruca necrogenica or anatomical tubercle, and Bazin's disease or erythema induratum. Examples of the tuberculide are found in acne varioloformis, acnitis, folliclis, acne scrofulosorum, and lupus erythematosus. The classification of lupus erythematosus as a tuberculide is vigorously disputed, so we will confine our attention to the admitted tuberculides, leaving acne scrofulosorum for indepepdent consideration at the end.

Acne varioloformis, acnitis, and folliclis are really variants of one disease. They are histologically identical. They differ only in location and sometimes in size. It is as if one should attempt to distinguish ordinary acne into three diseases, namely, acne faciei, acne dorsi, and acne brachii. They would all be acne and nothing else. So with the three titular diseases under consideration. They are simply tuberculides, differently named to the everlasting glory of some discerning dermatologists and the everlasting confusion of most of the profession.

Acne varioloformis occurs mainly in the scalp, on the forehead, on the temples, on the ears, and on the cheeks in front of the ears. Acnitis shows a tendency to fill in the space left vacant by the preceding, namely the chin, cheeks below the orbit, upper lip, and upper eyelids.

Folliclis attacks the limbs, especially the forearms, legs, hands, and feet. The differences between these three conditions are purely arbitrary, largely fanciful and of no practical importance whatever. It is the reproach of specialism that it tends to split the obvious into many trifling antagonisms, obscuring instead of clarifying the subject by unnecessary refinement in diagonsis.

Taking acne varioloformis as the type of the tuberculide it may be stated that it begins with an acne-like papule whose evolution leaves a pitted scar like that of variola. Hence the derivation of the name. On the papule appears a pustular top which dries down into a depressed scab giving the little lesion a saucer-shaped appearance. There is a destruction of tissue accounting for the synonym acne necrotica and the pitted scar. The disease is indolent. The duration of the individual lesion is about three of four weeks, but new lesions continue to appear, so that the disease as a whole may persist for months or years.

The lesions may be sparse or numerous. I have noted one peculiarity that does not seem to have been emphasized before, namely, a rough uniformity in the size of the lesions in each individual case. Small lesions predominate as a rule, but I have seen them as large as the old-fashioned three-cent piece. In the other extreme they may be no larger than a pin-head. The eruption gives little annoyance beyond a slight itching which is not always present.

A fact of some interest in connection with the etiology of this condition is that it is not confined to those with other evidences of tuberculosis, or with a tuberculous history. It is sometimes found in those apparently robust and healthy. Apropos of this, I was much struck by the statement of a physician attached to a prominent tuberculosis sanatorium in New York State, to the effect that tuberculosis cutis and tuberculides were uncommon in his experience. In fact, he was unfamiliar with their manifestations.

The lesion is an infective granuloma. There is a round-celled infiltration about the hair follicles or independent of them, followed by inflammation and necrosis. Tubercle bacilli have not been found in these growths. Their inoculation in the guinea pig has not produced tuberculosis. Sabouraud is of the opinion that the lesions have no relation to tuberculosis at all, but are produced by the conjoint action of the microbacillus of seborrhea and the staphylococcus.

His microbacillus produces the acne papule, and the staphylococcus the suppuration and scarring. Crocker remarks that this explanation is so beautifully clear it ought to be true, but he considers it strange that, if the conjunction of two such common organisms is all that is required, the disease should be so very rare. It might be answered that, if the presence of the tubercle bacillus or its toxins is all that is required, it is strange indeed that the disease is so very rare even in the frankly tuberculous. As the case stands we have to be content with a Scotch verdict "not proven." The only disease it is likely to be confounded with is a tertiary syphilide of almost identical appearance. Very acute differential diagnoses have been made between these cutaneous gemini, but truth to tell the distinction has rested often upon the *ipse dixit* of some eminent dermatologist, upon chance, or upon corroborative evidence of syphilis in the patient's skin or history. Of course if there is the characteristic crescentic grouping of syphilis, the distinction is plain. But in the absence of this it is frequently anything but plain. It is still further obscured by the fact that the therapeutic test, if applied for syphilis, is of little avail, iodide of potassium and Ung. Hydrarg. Ammoniat. operating successfully in both conditions. The Wassermann reaction in this stage of syphilis is positive only in about thirty per cent. of the cases. So the confounding of the two diseases is quite easy. The best means of differentiation are the Wassermann, if it chance to be positive, incriminating scars in other situations, or a history of luetic infection. Obviously there are cases so clearly one thing or the other, by reason of their course, duration, history, and other circumstances, that no mistake is likely. But in the border-line cases great care must be taken to avoid falling into error.

Treatment is effective and comparatively simple. The turberculide will frequently yield to the treatment for tertiary syphilis. It will also yield to applications suitable to acne indurata. If the therapeutic test mentioned above as being frequently misleading should take the form of treatment for the tuberculide instead of for syphilis, results of some value might be achieved; for the tuberculide will respond to the sulphur applications for acne (perhaps because of their antiseptic action) and the syphilide will not.

If the patient is below par suitable up-building remedies are indicated.

Acne scrofulosorum is a tuberculide which is not at all likely to be confounded with the three already considered. It occurs only in young children of strumous or tuberculous make-up. The sites of election are the buttocks, and the back of the thighs, but any part of the lower extremities may be affected. The eruption, as the name implies, consists of acneiform pustules, from the size of a pin's head to that of a pea, on an inflamed base. It comes out in scanty successive crops, leaving purplish stains but no scars. Pruritus is absent.

The treatment is that of the underlying cachexia, cod-liver oil, iron, hypophosphites, and a sustaining diet. Locally resorcin and sulphur ointments in low percentages are indicated. The results are speedily favorable.

Lichen scrofulosorum would appear to be a sort of admixture of acne scrofulosorum and lichen. It is not a real lichen. Some of the lesions resemble lichen papules, having the shape and the burnished top, but lack the lilac color. Other lesions are pustular. The eruption is on the trunk; rarely it extends to the face and limbs. Grouping in circles, and arcs thereof, is a pretty common arrangement. The victims are always children with direct evidence of, or a pronounced tendency to, tuberculosis. There is little likelihood of this rare disease being the cause of any confusion in the differentiation of the tuberculides.

Something has been said, I hope, to simplify the subject of the tuberculides and render their diagnosis less perplexing. As a final word I would reiterate the injunction to keep in mind the identity of type in these nominally different diseases, the type being the papule with the necrotic top eventuating in a depressed scar. Avoid distinction by titles. It makes no difference what else you call the lesion provided you properly call it a tuberculide.

315 West Fourteenth Street.

## THE PREVENTION OF ADENOIDS.

By WILLIAM BRADY, M.D.,

ELMIRA, N. Y.

So far as we are aware, the chief function of the ring of adenoid tissue surrounding the common orifice by which air, food, and water enter the body is that of guarding against the various infections which may gain entrance in the media of air, food, or water. This, from clinical and physiological observation, seems to be the purpose of the pharyngeal tonsils, the lingual tonsil, and the "nasal tonsil" or mass of lymphoid tissue which normally occurs in the nasopharynx of the growing child.

Some authorities, however, question the premises stated. It appears that partial or total extirpation of the ring of lymphoid tissue subjects the patient to no additional susceptibility to disease. The appendix, too, is richly endowed with lymphoid tissue, and while the appendix, like the tonsils, probably has some important function in connection with fetal and infant life and development, we observe no marked indications of injury to the health as a sequence of its surgical removal, even though it be a normal appendix.

The Cause of Adenoid Hypertrophy in Children.—Without denying the possible influence of mouth-breathing as a predisposing factor of hypertrophy of the nasopharyngeal adenoid tissue, it is difficult to believe that a child would acquire such a habit if the nasal chambers were not abnormally contracted. Children are the greatest imitators in the world, it is true, and one mouth-breather in a schoolroom may start a lot of unconscious mimicry, but is it not more logical to consider the habit of mouth-breathing as a result rather than a cause of nasal stenosis? That is to say, is not the child, with his naturally narrow nasal chambers, forced to open his mouth in order to breathe freely whenever the mucosa becomes turgescent from any cause

Anyone who has done special work on the nose and throat must agree that the infant's and young child's nasal chamber is a very restricted canal, and that its lining responds with wonderful alacrity to every temporary alteration of the general physical state. And even the general practitioner who never attempts to make rhinological or nasopharyngeal inspections must be aware of the fact that the lack of "resistance" on the part of the child's nasopharyngeal mucosa accounts for more than half of the diseases of childhood. These truths being admitted, why is the nasal and pharyngeal mucous membrane sought out by the bacteria of so many diseases? And what can be done to increase the local and general resistance of the growing child to these dangerous infections?

The foremost factor of mouth-breathing with its attendant evils is the intolerable atmospheric condition of the average home. We are not harping on the usual string here; we have no complaint whatever to make about draughts—except that there are not enough draughts—nor about unequable heating, excessive dryness of the air, and all that sort of old-fashioned "health" advice. The fault lies not with our methods of heating, but with the ultra-American habit of overheating the dwelling through the greater part of the year. You will find the idea beautifully expressed by a picture in a well known advertisement of steam radiators—a picture of Mr. Luxury-lover enjoying his morning panatella in slippers and pajamas, as he stands gloating with his back to the heat.

Adenoid and tonsillar hypertrophy is merely a concomitant or side issue of the "Indoor Plague." Having coined that horrendous appelation for the so-called common cold, it is but fair to interpret its meaning. By the indoor plague we would understand not only coryza with its manifold complications, medical as well as surgical, but also diphtheria, tonsillitis, and quinsy, influenza (not "grippe"), bronchitis, pleurisy, pneumonia, and pulmonary tuberculosis. These all too common maladies are known to be acquired solely through bacterial infection, whatever be the "predisposing" factors; and every one of them, from coryza to consumption, is caught through personal contact with a victim of the indoor plague or an unrecognized germ-carrier indoors. While it is unnecessary to discuss the pros and cons of the foregoing in this place, we would emphasize the neglected truth that vulgar, everyday, so-called "cold in the head" is just as contagious as is diphtheria or consumption if one comes into intimate contact with the patient indoors.

"Catarrhal tendency" is the vague term that describes the rebellion of the oxygen-starved lining of the nose and throat against excessive warmth in living-rooms or sleeping-rooms. The thickening of the mucosa accompanying that condition is invariably attended with an overgrowth of the mucous glands. The adenoid tissue in the fossa of Rosenmüller and the posterior pharyngeal wall ultimately takes part in the hypertrophy of congestion, and then the child has "adenoids."

Modern progress in therapeutics has demonstrated beyond a doubt the preventive and curative influence of outdoor life, at least in the case of pulmonary tuberculosis. And I am sure the better informed practitioner will agree that the same truth applies with even greater force in the case of pneumonia. If cold air exerts such marvelous effects upon these plagues, how much more powerful must be its preventive and curative influence upon the milder infections of the upper air passages. How much more certain is its

power to prevent the sundry more or less disabling infections which are thoughtlessly grouped under the misleading title, "a simple cold."

In these days of fresh air and common sense, the observing physician cannot help noticing how uncommon that one time disturber of the night has become—croup. The open bedroom window is robbing the night of its terrors for the mother, and robbing the doctor of many a hurried summons from sleep. Adenoids and croup are right-hand partners. Where one is common, the other is invariably present. Nature's germicide-tonic seems to be making good headway against both.

After a few months' incarceration in an overheated house a child becomes very susceptible to "head colds," or infection with the bacteria of the indoor plague. Hence his misguided guardians feel it incumbent to keep him indoors most of the time when he would naturally wish to be out playing in the snow. Thus warmth plus ignorance—for both of which evils the family doctor is to blame—keep the unfortunate youngster ever ripe for fresh "colds," and each acute attack leaves behind it a further thickening of the insulted adenoid tissue, until it finally dawns upon the mystified parents that in spite of their extreme care about exposing the poor child to the weather, there is something serious the matter.

Prevention is Better and Easier than Cure.—Were it only to save the growing child from the esthetic blemishes caused by adenoids, every possible means of prevention should be employed. But the damage to physical beauty and mental efficiency is a minor consideration as compared to the effects of the condition on the child's present and future health.

Since weather-phobia and excessive indoor life in overheated apartments produces the soil upon which adenoids develop, the sensible way to prevent adenoids is to permit and urge the children to play outdoors in all kinds of weather, regardless of grandma or Doctor Coddle, and to send them to schools where the open-air idea is practised. The sole precaution to be observed in keeping the youngsters outdoors in "inclement" weather is the one that any but an idiotic child is fully capable of looking after himself—personal physical comfort. The child who does not know enough to come in when he gets too cold to enjoy himself is not sick, but is weak-minded.

Porch bedrooms or near-porch bedrooms are so rapidly gaining adherents that they need no champions. Families who possess sufficient intelligence to acquire the Arctic bedroom habit seem to be entirely too smart to have coryza, adenoids, and croup in the house.

In view of Dr. Hill's recent investigations and our everyday experience, the principal prophylaxis against adenoids is the avoidance of overheated living-rooms. Instead of the usual temperature of 75° F. or more, the family should be taught to acclimate themselves to an average of 60° to 65° throughout the winter. If the effort is made at the beginning of cold weather in the fall, and the household temperature is regulated by the thermometer and not by personal feelings, such a moderate temperature will be comfortable to everybody, from baby to grandma herself. And with the removal of the enervating, debilitating influence of highly heated air the nasopharyngeal mucosa will have a fighting chance against its daily assailants. This means that there would be no adenoids.

## A DROP METHOD OF GIVING ETHER WITH A CLOSED INHALER.

By CHARLES P. BULL, Jr., M.D.,

CANANEA, SONORA, MEXICO.

PHYSICIAN TO THE CAPOTE HOSPITAL.

Ether, for the present at least, must be the routine anesthetic. The disadvantages of ether have been greatly lessened by the use of ingenious mechanisms, by which the ether vapor is administered and maintained throughout at a very uniform strength. In the few institutions thus equipped, and with a skilled anesthetist perfectly familiar with the mechanism, not only is danger diminished, but ether anesthesia loses much of its, not undeserved, unpleasantness and dread. However, among the large number of anesthesias daily given throughout the country, in how many instances would we find such a comparatively simple apparatus available as a Bennett inhaler? Furthermore, of the great number of anesthesias daily given throughout the land, the majority must be administered by men who owe their living to a time-consuming general practice and who cannot, more than in a general way, become specialists. Simple, indeed, must the device or method be to find its way into more than the most restricted use, and, therefore, become more than a trifling factor in diminishing the danger, ever present in anesthesia, and the disagreeable features of ether anesthesia.

The vehicle, or diluent, of the ether vapor is atmospheric air. Therefore, to secure and to maintain a perfect mixture of air and ether vapor, in the desired proportions, is what we wish to attain. If gasoline were administered to an automobile, for instance, as ether not infrequently is administered to patients, the engine would refuse to work. Not so with our patients, for nature has endowed them with powers of compensation and tolerance sufficient to endure the insult which the man-made machine will not. However, hypersecretion of the muciparous glands, laryngeal spasm, cyanosis, and fluctuations of pulse, blood pressure, and respiration, are among nature's many protests against uneven ether mixtures.

A drop method is apparently necessary to maintain uniform strength of the vapor. The open drop method deserves its popularity because it has been a step forward. It has removed the two great objections to ether, when it was given in a closed cone, namely, anoxemia, and intermittent periods of over concentration of ether vapor, with their numerous very undesirable consequences. Beyond the removal of these two serious objections, what has the open drop method to recommend it?

Gatch says, "When we give ether by the open method we take a very efficient means of producing acapnia." He calls attention to the primary stimulating effect of ether upon the respiratory center, and the consequent over-ventilation of the lungs. The result of this must be a reduction of the carbon dioxide, below the normal proportion, in the complemental and residual air.

When we give ether by the open drop method the current of air expelled during expiration is expelled directly against the surface of the mask, and the expired air is disseminated as lateral air currents and lost. During inspiration some of the inspired air is aspirated through the gauze carrying the ether, but most of it is taken in by the paths of least resistance, the open space around the edges of

the mask. Ether vapor is very light, and in order to give enough of the vapor to induce anesthesia the mask is frequently held very close to the patient's face. This diminishes the amount of air dilution from the open space around the mask, but when the mask, wet with ether, is held close to the face the small air space intervening affords a very inadequate mixing chamber. The rapid evaporation of the ether greatly chills the inspired air, and furthermore, the cold, concentrated vapor has no opportunity to become evenly mixed with the inspired air. Warming the anesthetic (by placing the can or bottle in warm water) by increasing volatility, enhances the change from a liquid to a gaseous state. With ether, however, this transition occurs so quickly and utilizes so much of the latent heat of the surrounding air that after warming the liquid anesthetic as much as practical, the vapor will still be cold and therefore concentrated.

Frequently a towel is placed around the edges of the mask, shutting off the lateral air currents, and practically converting the mask into a cone. The objection to this procedure is that the mask is nearly always held close to the patient's face, and the ether vapor traverses too small an air space, before being taken into the lungs, to allow it to become warmed and well mixed with air.

Suppose, instead of a towel, that the lateral air currents are shut off by a cone, like the old closed cone made of a newspaper and a towel, and about the size of a quart tomato can, with ends removed and sides flattened enough to give the desired oval shape. Suppose the top of the cone is closed by laying several layers of gauze over it, and that onto this gauze the ether is dropped. The gauze then becomes the mask. What results? The ether is still administered by dropping it onto a mask. The current of tidal air expelled during expiration leaves the cone filled with warm expired air. During inspiration the ether on the gauze is aspired through an air chamber already filled with warm air, in which the vapor readily diffuses. By the time the ether vapor traverses five or six inches of warm air space, and reaches the mouth and nostrils of the patient, it has been pretty thoroughly mixed with air and is warm.

The Allis inhaler is somewhat similar to the cone I have described, but the air chamber is not sufficiently deep to accomplish my purpose, and is only partially closed above by folds of gauze arranged like a window shutter when the slats are open. It, therefore, fails to retard the diffusion and loss of the expired air as does the cone I have described. I purposely close the top of the cone with a flat roof of gauze. This is sufficiently porous to allow the act of inspiration to aspirate the ether vapor readily into the cone. It also offers just enough obstruction to the current of expired air to keep the cone full of warm expired air for the ether vapor to diffuse into during the following inspiration. The number of respirations are considerably increased during ether anesthesia. The lungs are, therefore, more or less over-ventilated, and the amount of carbon dioxide, in the complemental and residual air, is below the normal.

The gauze roof of the chamber offers sufficient obstruction to the expired air so that at the beginning of inspiration the air chamber is full of expired air. Rebreathing, in a considerable degree, is thus accomplished without causing anoxemia, because a few layers of gauze offer very little obstruction to the patient's breathing. Rebreathing aids in conserving the normal amount of carbon dioxide in the lungs and, therefore, in diminishing the danger of acapnia and shock.

If the anesthetist wishes to concentrate the ether vapor, additional layers of gauze, permitting the use of more ether, may be used, or, the cone may easily be closed, partially or completely, by a towel over the gauze top.

## Medicolegal Notes.

**Expert Evidence of Physicians Examining Plaintiff to Testify as to Injuries.**—In an action for injuries received by a passenger traveling in the caboose of a train when a collision occurred, it appeared that the plaintiff was thrown eight or ten feet from his seat against a wooden partition, striking it with his head. He was rendered unconscious for a time; received cuts and bruises; several of his teeth were broken or knocked loose; and he was injured in the back of his neck and in the region of his stomach. There was evidence tending to show that for almost eighteen months, and up to the date of the trial, he was incapacitated from following his employment as a traveling salesman; and that, besides his health being affected in various ways, he had many of the symptoms that precede paralysis. The chief point in the case was whether the evidence received as to the possible permanence of his injuries and consequent damages was competent. It consisted almost entirely of the testimony of physicians who had examined him, not in the regular course of treatment, but for the purpose of qualifying themselves as witnesses upon the trial. One of these witnesses, who had in this way examined the plaintiff on three different occasions, was permitted to state, over objection, that the muscles of the plaintiff's neck were rigid and stiff, and of limited motion; to state to what extent the motion of the head was affected by the muscular condition which he found; that the motion of the plaintiff's left arm was limited and painful, and the motion of the right arm much better; that he tested the motion of the arm by taking the patient by one hand and shoulder and rotating the arm; that the superficial reflexes were tested by pricking the skin with a pin and that they were sluggish and nonresponsive. He was also permitted, over objection, to elaborate that symptom, and upon it, in conjunction with others, to express his opinion that the conditions indicated by such symptoms were the natural result of some kind of a concussion. He was also permitted to state, over objection, that at an examination of the plaintiff on the day previous, "the perspiration just oozed out of him and streamed down the side of his face and all over him"; that a man could not simulate sweating; that the plaintiff was stripped at the time and that "he was doing as we told him and standing up and attempting to bend his body, or whatever else we told him"; and that in the opinion of the witness the cause of the sweating was "exhaustion." He was further permitted to give his opinion, based upon the symptoms narrated by him, that there was an injury to the plaintiff's spinal column and to the medulla oblongata and the muscles of the back, and that in his opinion the injuries indicated by the symptoms mentioned by him were growing worse, and that in the future the plaintiff would be paralyzed on the left side and his life shortened.

It was held to be improper to permit these witnesses to express their opinions to the jury based upon subjective conditions, and then to fortify such opinions by stating to the jury acts of the injured party which could apparently have been voluntary and under the injured party's control, and which might have rested upon another basis than the truthfulness of the injured party. In Illinois the law is that a physician who has not treated the injured person, but has made an examination to enable him to testify on a trial as to his condition, must base his opinion on objective and not subjective conditions. He cannot relate nor take into consideration the self-serving statements of the injured person made to him, not with reference to his treatment, but with reference to his trial. The law admits in evidence the declarations of an injured party as to his physical condition given to physicians during treatment, because it is presumed that the injured party will not falsify in his statements made to the physician when he expects and hopes to receive medical aid; but no such presumption arises when he is examined by an expert for the purpose of giving evidence in a case about to be tried.—Edward v. Illinois Central R. R. Co., 161 Ill. App. 630.

## DIPHTHERIA AND ITS PRESENT-DAY PROBLEMS.

THERE are many problems relating to diphtheria that still remain unsolved. The remarkable reduction in mortality that followed the general use of the specific serum aroused the hope that the absolute control of diphtheria was close at hand. Nevertheless the conviction soon dawned that the antitoxin was not a specific in the strictest sense. It is efficacious only during the first three days of the disease. There are severe cases in which the overwhelming infection cannot be subdued even by massive doses of the serum. The immunity, whether active or passive, is only of short duration. The incidence of cardiac complications and of postdiphtheritic paralyses apparently has not been affected by the antitoxic treatment. Moreover, this has little or no influence over the persistence of the diphtheria bacilli in the throats of convalescents and of healthy individuals, so that the problem of the carrier is still an important one. However, one must recognize the fact that the prompt and liberal administration of the antitoxic serum has robbed diphtheria of most of its terrors, has diminished its prevalence, and has saved many lives. The army of research is now no longer engaged in resisting the main body of the enemy, but is able to turn its attention to the flanking columns.

Until recently the chief point of attack in the investigaion of the pathogenic properties of the Klebs-Loeffler bacillus was its soluble toxins. Little or no heed was paid to its insoluble poisons or endotoxins, for it was thought that these take no part in the production of the morbid phenomena of diphtheria. Moreover, they play no rôle in the mechanism of immunity and cure dependent upon the elaboration and use of the curative serum of Behring and Roux. The pendulum, however, is now swinging in the direction of a discovery of the actual pathogenic properties of the endotoxins of the diphtheria bacillus, and of a possible therapy based partly upon these endotoxins.

One of the pioneers in the investigation of the latter was E. Rist of France, who in 1903 showed that the endotoxins of the diphtheria bacillus have pathogenic properties, for he was able to produce, by means of intraperitoneal inoculations of these endotoxins into guinea-pigs, paralyses similar to the clinical forms. The next important contribution to this subject was that made by Hewlett and Nankivell (*Lancet*, July 20, 1912), who utilized the injections of diphtheria endotoxins in the treatment of diphtheria carriers or of chronic cases of diphtheria (see MEDICAL RECORD, August 10, 1912). The latest and apparently an epoch-making announcement along this line is the recent report from Behring that he has found a combination of diphtheria antitoxin and toxin to be the ideal means of creating active immunity, and the ideal remedy in combating this disease.

During the past few years there has been a pronounced recrudescence of diphtheria in Germany, a circumstance which is apparently inexplicable in view of the improved sanitary conditions and the widespread use of antitoxin. This epidemic has, however, furnished the opportunity for important clinical and pathological studies. One of the latest of these was that made by William H. Leede of the Hamburg-Eppendorf General Hospital, and reported in the *Zeitschrift für klinische Medizin*, Vol. 77, Nos. 3 and 4. This study was concerned chiefly with the pathological and post-morten bacteriological findings in relation to the clinical picture. The material that formed the basis of this investigation was a large one, comprising 3,671 cases that were under treatment in the hospital during 1910 and 1911. It was noted that the period of greatest incidence of this disease is between the fifth and fifteenth years of life. Females, particularly, after the fifteenth year, provide the larger number of cases, the latter circumstance apparently being explained by the opportunities of contact infection to which nurses and other female attendants are exposed. Cardiac disturbances were apparent in more than ten per cent. of the cases and were detected during the first few days of the disease. Indeed, heart failure in diphtheria does not come on suddenly as is commonly taught but gives early warning in unmistakable constitutional and cardiovascular symptoms. Since involvement of the heart is to be expected in the severe cases, heart stimulants should be administered to the latter from the very beginning. Leede obtained the best results with a combination of strychnine and suprarenal extract.

In spite of the severity of the Hamburg epidemic, the mortality of the author's 3671 cases was 12.47 per cent., a good showing in comparison with the appalling mortality of twenty and thirty years ago. The causes of death are classified as follows: (1) The entrance of an overwhelming amount of toxin into the bloodstream, with the resulting disastrous effects on the vasomotor centers, heart, and suprarenal capsules; (2) changes in the heart muscle chiefly of a parenchymatous nature, interstitial changes playing only a subordinate rôle; (3) affections of the bundle of His; and (4) bronchopneumonia, which is a more important factor than is generally recognized. Diphtheritic involvement of the lower air passages occurs very frequently at the present day though not to as great an extent as formerly. The hemorrhagic forms of the disease are apparently the result of a toxic damage of the endothelium.

The author made a systematic examination of the blood in all cases that came to autopsy, and

in 63 per cent. of these demonstrated a bacteriemia, the microorganism most frequently present being the streptococcus. In a few instances diphtheria bacilli were isolated. The positive results were found mostly in cases that presented evidences of bronchopneumonia. The author does not attribute any great importance to this bacteriemia and believes that at any rate it is rarely responsible for the lethal outcome.

It is curious to note that the Germans still employ tracheotomy in preference to intubation. Of the 3,671 cases, 271 or 7.38 per cent. were subjected to the former operation, with a mortality of 53 per cent. This high death rate either speaks against the value of tracheotomy, or else indicates the desperate nature of the cases that were subjected to this operation. The mortality from the latter was greatest during the first year (88 per cent.) and after the fifteenth year (62 to 66 per cent.). These figures were all the more significant in view of the fact that many of the cases received early in the disease large doses of antitoxin. There are certain personal factors in the evolution of laryngeal stenosis that baffle all therapeutic efforts.

One important lesson learned in the Hamburg epidemic was that the effective treatment of severe cases of diphtheria requires the early administration of large doses of antitoxin, preferably by the intravenous route.

## MORAL DEVELOPMENT IN MEDICAL EDUCATION.

We hear much of the necessity of increasing the moral tone of the medical profession, and recently we referred to a bill introduced into our legislature which proposes giving to the Board of Regents the power to revoke medical licenses for any conduct not consonant with good morals. Almost every State board requires a certificate of moral character and no one, we are quite sure, would deny the wisdom of this. The privacy of medical practice makes it impossible to observe how the obligations are fulfilled, and it is on account of this privacy that a greater degree of confidence and trust is called for than in any other profession. In law, for instance, one's true character is known sooner or later because there is not the protection of privacy or the opportunity of being excused by a possible change of conditions in the case as in medicine. Considering, then, how important it is that every member of the medical profession should be of the very highest moral character, it is strange that so little thought has been given to the subject of how moral development might be quickened during the course of medical education.

The physician's is a high calling. It should attract only those who are innately moral. But should nothing then be done to further the growth of this moral disposition? How shall the moral nature be promoted in the medical school? It goes without saying that the conduct of the teachers should be exemplary and that the prevailing spirit of the school should be for righteous conduct and a keen perception of duty; but it is in the method of teaching that we should be able to find concrete instances of the perfection of the moral sense if we are to avoid mere cant. In the average medical school, scabies, for instance, is taught by showing a case in the clinic and probably by demonstrating at some other time and some other place a cabinet specimen of the itch mite. In fact, the student is told only that the lesions observed are caused by the itch mite. Simply having been told he may have but a hazy recollection of the appearance of these lesions when, in later life, a case may present itself to him. Then, if he be given to moral obliquity, how easy it would be for him to yield to temptation and give himself the benefit of the doubt because he really does not know—telling the patient that it is eczema and treatment will have to be taken for a long period—so that he may gain more fees. But if, on the other hand, he had been practically trained and had been required to prove, to his own satisfaction, through finding in one of the lesions that the itch is caused by the mite, he would then know absolutely a case when it presented itself, and it would only be by the veriest kind of a moral upheaval that he would go contrary to his absolute knowledge of the case and his natural desire to tell the patient that it was caused by the mite and what he must do to get rid of it. This phase of teaching, the absolute presentation and demonstration of the *truth* to the student has a positive effect on his whole nature. It creates interest and enthusiasm; it develops manual skill, and the knowledge acquired besides giving a lasting personal satisfaction remains so indelible as to determine the course of action throughout the whole of life without permitting any equivocation.

The next phase of teaching which affords a concrete instance, as developing the moral sense, is practical work in the out-patient department. Here the student not only sees, but feels his responsibility and learns better than in any other place how much depends upon his doing his duty. If a case of lead poisoning is shown to him at the dispensary and he is taught to work up the case fully—visiting the home or factory if need be—he soon solves the problem of etiology. The satisfaction of having done so will last through all his years and the experience will show him how much depended upon his own initiative in finding out the cause and gaining relief for the patient by having it corrected. Nothing could stop him, when, in later life, a suspicious case presented itself, from leaving no stone unturned until he finds the cause. He again must have not only the pleasure of solving the problem, but he *feels* his duty to find the absolute cause, as no amount of *telling* could have made him. He must find the cause and then see to it that it is corrected! Other and numerous instances of the enlivening of the moral sense by this method will readily suggest themselves.

Another phase of teaching, which is especially conducive to developing deep feelings of responsibility on the part of the student in relation to his profession, is by showing mistaken diagnosis on the autopsy table. Each case in such teaching points a moral, but above this is the magnanimous attitude and honesty of his teacher, the memory of which will always serve as a guide to right conduct and will give strength in hours of temptation.

The moral development of medical students, like that of children, is brought about less by precept than by all of the subtle influences which make up their daily life. It is the foregoing phases of teaching in a medical school that enrich that life.

## THE CURABILITY OF INSANITY.

At one time American alienists were enthusiastic concerning the curability of insanity, and their figures seemed to show that their enthusiasm had a sound basis on which to rest. Statistics used to be cited to the effect that 80, 90, and even a larger percentage had been discharged cured. Cold reason has now taken the place of enthusiasm and statistics of the present time give evidence that the percentage of cures in American hospitals is nearer 20 than 90. In a paper contributed to the *American Journal of Insanity* for April, 1913, Dr. A. J. Noble of Kalamazoo, Mich., points out that statistics given out by different institutions for the treatment of the insane are not wholly to be depended upon, and he goes on to give the figures of the Kalamazoo State Hospital during the two years between July 1, 1910, to June 30, 1912, assuming that Kalamazoo State Hospital in point of efficiency occupies an average place with respect to the other institutions of the state and county. There were committed to the hospital during the period referred to 960 patients. Of these 381, or about 40 per cent. were suffering from what might be termed curable forms of disease, and 579 from incurable forms. The recovered tabulated in the two years were 93, or 9.5 per cent. of the admissions, those discharged as improved 10.19 per cent., unimproved 7.22 per cent., while 20.79 per cent. died, and 48.87 per cent. remained in the hospital. In the six months following the period the remnant was reduced to 35.44 per cent. and the cured had been increased by 2.40 per cent., making the total cures in two and a half years 11.9 per cent. of the original admissions. Moreover, there was a probability that 2.58 per cent. more of these patients would eventually recover. Disregarding the small and uncertain percentage of patients who may have recovered at home, this would make possible, so far as these particular patients are concerned, a complete recovery rate of 46.48 per cent., and applying Thurman's rule, a permanent recovery rate of approximately 16 per cent. Thurman deduced the following general rule: "In round numbers, of ten persons attacked by insanity, five recover and five die sooner or later during the attack. Of the five who recover, not more than two remain well during the rest of their lives, the other three sustain subsequent attacks, during which at least two of them die."

Noble believes that the rate will not be materially bettered. He further is of the opinion that alcohol, directly or indirectly, is a potent factor in the production of insanity and the various neurotic conditions which are so apt to develop into psychoses. Finally Noble propounds the radical opinion, that alcoholics should be colonized, that the epileptics and feeble-minded should be segregated, colonized, and sterilized, and that this should be done at once.

## The Cocaine Law in Canada.

A few years ago in Montreal and in some other parts of Canada, the abuse of cocaine had reached such heights and the evil wrought had become so obvious that the aid of law was called in to check the fast-growing menace. An act was put into force in Canada in 1908, whereby the presence of cocaine in proprietary or patent medicine was absolutely forbidden. However, it appears that politics are strong in the Dominion as well as elsewhere, for this wise act has been set aside in favor of a proprietary medicine. A popular so-called specific for asthma had been retailed far and wide in Canada, but when the act came into force the sale of the remedy, one of the main ingredients of which was cocaine, was stopped. At once a cry went up from the many users of the drug and protests and pleas rained in on members of parliament. So strong does the pressure seem to have been, that instructions have been issued to collectors of customs throughout Canada to permit importations of the proprietary medicine in question. The *Canadian Medical Association Journal* comments on this action as follows: "With the legal aspects of the case we are not concerned at the moment, although it is worth remarking that there is no provision in the act which warrants any minister, or the Government itself, in breaking it. We have the utmost sympathy for sufferers from asthma, and even more if possible, for sufferers from the cocaine habit. At a time when the use of cocaine is so widespread, and when the courts are making such desperate efforts to check it, it is an ill-timed procedure, this flooding of the country with the drug through a legalized channel. Sufferers from asthma have still the services of the profession at their command, and can procure cocaine for a legitimate purpose in a legitimate way."

## Influence of the Upright Posture Upon Mankind.

Despite the great antiquity of man it does not appear that he has yet succeeded in adapting himself thoroughly to the change from the quadrupedal state. Or perhaps it is better to assume that he had at one period succeeded in such adaptation, but that under the influence of civilization the structures most active therein began to lose the power of compensation, so that all the original drawbacks of the bipedal state have once more reasserted themselves. At a recent session of the medical section of the silesian Society for National Culture held at Breslau (*Berliner klinische Wochenschrift,* April 14), Klaatsch read a paper on this subject. Numerous affections of mankind which have no analogues among quadrupeds are distinctly favored if not essentially determined by the upright posture which allows a pull of gravity not experienced in a virtually prone position. Here belong especially hernias, hemorrhoids, varicose veins, enteroptosis, intestinal stasis, and conditions peculiar to women, gravid and nongravid. The backache of delicate women is no doubt due to the insufficiency of the trunk muscles for the maintenance of the upright attitude. The conditions which result in mankind are in striking contrast, Klaatsch assumes, to those seen in the bipedal kangaroo, which has apparently succeeded completely in adapting itself to the upright posture.

### "Rheumatoses" of Nasal Origin.

The expression "rheumatoses" is sometimes heard in connection with minor affections which have a distinct rheumatic component, such as erythema nodosum, peliosis rheumatica, and chorea minor. The term serves to distinguish these from the frankly rheumatic affections of the synovial membranes, tendon sheaths, endocardium, etc. At a recent meeting of the Freiburg Medical Society (*Münchener medizinische Wochenschrift*, April 8), Senator, who has identified himself with the occasional endonasal origin of rheumatism *per se*, made the claim that the "rheumatoses" may exhibit a similar origin. A case of a child was cited in which the removal of adenoids was followed by chorea minor. It is known that this operation is not infrequently followed by infection. The author has seen one case analogous to the preceding. The recorded cases of rheumatic or at least rheumatoid infection, and of rheumatoses, which have been noted after tonsillitis, sinusitis, and other spontaneous conditions, as well as after endonasal and endopharyngeal operations, while few in number, possess an unequivocal character which should form a datum for future studies.

## News of the Week.

**Health Reform Bills.**—On May 17 Governor Sulzer of New York signed the bill known as the Seeley-McDaniels bill, which was passed recently by the New York State Legislature, and is designed to carry into effect the recommendations of the special Public Health Commission appointed by the Governor last January. The chief provisions of the bill are as follows: A public health council is created to consist of the State Health Commissioner and six members appointed by the Governor, which shall have power to enact and amend the sanitary code. Three new divisions, each in charge of a director (Child Hygiene, Public Health Nursing, and Tuberculosis) are added to the Department of Health, and the six divisions (Administration, Sanitary Engineering, Laboratories and Research, Communicable Diseases, Vital Statistics, and Publicity and Education) already established, are written into the statute. The State is to be divided into twenty or more sanitary districts, each under a sanitary supervisor who shall be a physician and whose duties are detailed. The Health Commissioner is given a six years' term of office with an annual salary of $8,000, and the health officers throughout the State are ensured a respectable compensation, and their duties are plainly defined. The regulations regarding the registration of cases of tuberculosis are to be more strictly enforced, and health authorities are given control over "persistently dangerous and careless persons, afflicted with an infectious, contagious, or communicable disease, the law providing for the commitment of such a patient to a hospital by a magistrate upon proof that he is a menace to the community.

The Governor also signed the Seeley bill giving the State Health Department increased powers over cold storage plants, and the Foley bill providing for an inspection by the Health Commissioner of the kitchens of all hotels, restaurants and other public places.

**Changes at Ellis Island.**—Surgeon L. L. Williams of the United States Public Health Service assumed the duties of chief medical officer at Ellis Island on May 15, relieving Dr. George W. Stoner, who has been assigned the command of the U. S. Marine Hospital at Stapleton, S. I. Dr. Stoner has completed twelve years' service at Ellis Island. Dr. Williams has had previous experience on the Island, having been in charge there in 1900-01, and has had much to do with immigration and public health work in this country and abroad.

**Quarantine Station.**—Dr. John R. Hicks has been appointed chief medical officer of the Detention Hospital on Hoffman Island, and Dr. Albert A. Mendez has been selected as chief medical officer of the Contagious Diseases Station on Swinburne Island. Dr. F. C. Clark and Dr. C. S. Hudson, after three years' service on the quarantine islands, have been promoted to the positions of Deputy Health Officers, and are now assigned to boarding duty at Rosebank.

**City Death Rate.**—During the week ending May 10, there were in New York City 1,543 deaths, giving a death rate of 14.98 per thousand of population, as compared with a rate of 14.73 per thousand, and a total of 1,461 deaths for the corresponding week of last year. The mortality of children under five years of age was decreased as compared with last year, but in all the other age groups an increase occurred.

Statistics recently compiled by the New York City Department of Health show that the incidence of typhoid fever was much less during 1912 than during any year since records have been kept. The total number of cases in the city during the year was 3,076, and there were 499 deaths, giving a case incidence of 59 and a death rate of 10 per 1,000 of population. In 1911 the case incidence was 10 points greater.

**No License for Friedmann.**—The Commissioners of the District of Columbia have decided that the efficiency of the Friedmann treatment of tuberculosis has not been sufficiently established to warrant the granting without examination to Dr. Friedmann of a license to practise medicine in the District. In a report of Congress they state that they are opposed to the bill introduced by Senator Hughes of New Jersey, directing that such a license be granted.

Four of the patients in whom the Friedmann culture was injected have died. If many more fatalities occur the question may be raised whether the hospital authorities are justified in exposing their patients to the danger of these experiments.

**Health of the Canal Zone.**—The report of the Department of Sanitation of the Isthmian Canal Commission for the month of March gives the total number of deaths from all causes among employees as 32, of which 19 were due to disease and 13 to violence. The annual average death rate per thousand is given as 6.82, as compared with 10.76 in March, 1911, and 8.45 in March, 1912. The annual average death rate per thousand in the cities of Panama and the Canal Zone, including both employees and civil population, however, was considerably higher as compared with last year, being 19.32 in March, 1913, and 14.67 in March, 1912. Among employees the principal causes of death were lobar pneumonia, 3; tuberculosis, 7, and duodenal ulcer, 2. No cases of yellow fever, smallpox, or plague originated on or were brought to the Isthmus during the month.

**An Investigation of Fractures.**—Dr. John B. Roberts, 315 South 17th Street, Philadelphia, chairman of the Committee on Fractures of the American Surgical Association, writes that the committee

desires to have two reprints of any paper dealing with the nonoperative or operative treatment of open or compound fractures which has been published within the last five years. The committee also desires papers on the medicolegal relations of radiography to the diagnosis and treatment of fractures. If authors on these subjects have no reprints the committee would be pleased to receive memoranda of the places of publication of such papers.

**Osler's Practice of Medicine.**—In a review of this work recently published in the MEDICAL RECORD it was stated that the book was in its twelfth edition; this was an error, the latest edition and the one noticed in the review being the eighth.

**Bequests by Dr. Duhring.**—By the will of the late Dr. Louis A. Duhring, formerly professor of diseases of the skin in the University of Pennsylvania, his manuscripts on cutaneous diseases, as well as his notes of medical cases have been devised to the university, with directions that they be edited by an expert and published. His medical library also is bequeathed to the university, with the proviso that duplicate volumes are to be given to the College of Physicians of Philadelphia, and the sum of $3,000 is devised to the University library without stipulation. The sum of $3,000 is bequeathed to the trustees of the university as a permanent fund for the care of his medical works, portraits, drawings, photographs, and models. To the Department of Diseases of the Skin of the university are bequeathed all drawings, paintings, lithographs, plates and photographs relating to medicine. The College of Physicians of Philadelphia is to receive $5,000 in trust for the purchase of works on the subjects of cutaneous medicine and surgery. A trust fund of $25,000 is created, and the income from this is to be used for the benefit of the Department of Cutaneous Medicine at the university, and in which there is to be established a museum for the study and observation of skin diseases. If any of the income from this source becomes available for other purposes it is to be used for lectures, prizes, scholarships and methods of promoting a knowledge of the nature, pathology, and treatment of cutaneous disorders. To the managers of the Hospital of the University of Pennsylvania the sum of $50,000 is bequeathed for the establishment and maintenance of wards containing free beds for the treatment of "cutaneous, cancerous, and allied affections." The sum of $5,000 is devised to the Mutual Aid Association of the Philadelphia County Medical Society. The residue of the estate is bequeathed to the trustees of the University of Pennsylvania and to be devoted in equal parts as follows: One-third for the general library, one-third for the maintenance of free beds for the treatment of diseases of the skin, and one-third to the Department of Cutaneous Medicine for the advancement of the study of diseases of the skin.

**Charitable Bequests.**—By the will of the late Mr. Hugh D. Auchincloss of New York the Presbyterian Hospital receives a bequest of $7,500 for the endowment of a bed in memory of the testator's mother.

The Montefiore Home, Mount Sinai Hospital, the German Hospital, the Skin and Cancer Hospital, and the Society for the Ruptured and Crippled, all of New York, will receive $1,000 each from the estate of the late Mr. Charles Schoolhouse.

The Montefiore Home and Mount Sinai Hospital receive bequests of $1,000 each under the will of Moritz H. Rosenstein, and of $2,500 each under the will of the late Emanuel Heilner.

Bequests of $100 each are made to Beth Israel Hospital and Mount Sinai Hospital in the will of the late Mr. Morris Rothman of this city.

**To Endow Medical Research.**—The University of California has received a gift of $1,000,000 for the establishment of an institution for research in connection with the Medical Department of the university. The gift is made by Mrs. George William Hooper of San Francisco in memory of her husband.

The University of Cincinnati has received from Mrs. M. M. Emory of that city a gift of $125,000, to be used for the endowment of a chair of pathology in the Department of Medicine.

**A Correction.**—Dr. Mary Sutton Macy writes that, in the report of the Pediatric Section of the State Medical Society on p. 918 in the issue of May 17, the statistics of 10,000 cases of physical defects in children, quoted by her, should have been credited to Dr. Smart by whom they were originally presented at the Congress on Hygiene and Demography.

**Milwaukee Law Upheld.**—The Supreme Court of the United States has declared valid the Milwaukee city ordinance prescribing standards of pure milk. The dairymen of the State had been refused an injunction against the enforcement of the ordinance in the lower courts and had carried the fight into the Supreme Court. The ordinance prohibits dairymen from supplying milk to Milwaukee unless their cows are subjected annually to the tuberculin test and passed by a veterinarian, requires that every bottle be tagged with the name and address of the dairy, and gives to the Health Commissioner the authority to seize and destroy milk sold in violation of the ordinance.

**International Dental Congress.**—By invitation of the British Dental Association the Sixth International Dental Congress will be held in London from August 3 to 8, 1914, under the patronage of King George. The offices of the congress are at 19 Hanover Square, London, W., to which address all communications and requests for information should be sent.

**Massachusetts State Medical Society.**—The 132d anniversary of the Massachusetts State Medical Society will be celebrated by a meeting of the society in Boston on June 10 and 11, for which an elaborate program has been prepared. On the evening of the first day Dr. Harvey Cushing will deliver the annual Shattuck lecture on "Diabetes," and on the following evening the annual dinner will be given at the Copley-Plaza.

**Iowa State Medical Association.**—At the closing session of the 62d annual meeting of the Iowa State Medical Society on May 9 the following officers were elected: *President*, Dr. L. W. Dean, Iowa City; *Vice-Presidents*, Dr. F. S. Smith, Nevada, and Dr. F. A. Stettman, Ottumwa; *Treasurer*, Dr. W. B. Smith, Waterloo. The next meeting will be held at Sioux City.

**West Tennessee Medical and Surgical Association.**—At the annual meeting held in Jackson on May 9 the following officers were elected for the ensuing year: *President*, Dr. J. R. Carroll, Henderson; *Vice-Presidents*, Dr. I. C. Rawls, Dyersburg, and Dr. O. S. McCown, Memphis; *Secretary and Treasurer*, Dr. I. A. McSwain, Paris.

**North Dakota Medical Association.**—The following officers were elected at the 26th annual meet-

ing of the North Dakota State Medical Society on May 7: *President*, Dr. Murdock McGregor, Fargo; *Vice-Presidents*, Dr. R. H. Beek, Lakota; Dr. Victor H. Stickney, Dickinson, and Dr. A. Carr, Minot; *Secretary*, Dr. H. J. Rowe, Casselton; *Treasurer*, Dr. C. S. Crane, Grand Forks.

**McPherson County (Kan.) Medical Society.**—At a meeting of the physicians of McPherson County held on May 2 a county medical society was organized with the following officers: *President*, Dr. L. A. Bradbury, McPherson; *Vice-President*, Dr. Harry Edgerton, Canton; *Secretary-Treasurer*, Dr. G. R. Dean, McPherson.

**Atchison County (Kan.) Medical Society.**—After being dormant for several years this society was revived at a meeting held at Atchison on May 5, the following officers being elected: *President*, Dr. M. T. Dingess; *Vice-President*, Dr. G. E. White; *Secretary-Treasurer*, Dr. E. T. Shelly.

**The Late Dr. Morrow.**—At a meeting of the Medical Board of the City Hospital, held May 1, 1913, it was directed that a copy of the following resolution be sent to the family of the late Dr. Morrow, to the MEDICAL RECORD, also to the *Medical Journal*, and the resolution spread on the minutes of the meeting: "The Medical Board of the City Hospital records with sorrow the death of Dr. Prince A. Morrow. Dr. Morrow was appointed dermatologist to the City, then Charity, Hospital in 1884, and was connected with the Dermatological Department up to the time of his passing away, the last few years as consulting dermatologist. The Medical Board wishes to record and express its appreciation of Dr. Morrow as a fellow member, and its sense of loss in his death. The Medical Board wishes to extend to the immediate members of Dr. Morrow's family its sympathy and sorrow." Signed WILLIAM B. PRITCHARD, President; DANIEL H. WIESNER, Secretary.

**Obituary Notes.**— Dr. GEORGE H. POWERS of San Francisco, emeritus professor of ophthalmology in the University of California, a graduate of the Harvard Medical School, Boston, in 1865; a surgeon in the United States Army during the Civil War; professor of ophthalmology and oto'ogy in the Toland Medical School and later in the Medical Department of the University of California after the amalgamation of the two; a member of the American Medical Association, the California State and San Francisco County Medical Societies, and the Section on Eye, Ear, Nose, and Throat, San Francisco, died at the home of his daughter in Detroit, Mich., from disease of the heart, on May 4, aged 72 years.

Dr. LEONARD BAILEY of Middletown, Conn., a graduate of the Eclectic Medical College of Pennsylvania, Philadelphia, in 1857, and president of the Connecticut State Eclectic Medical Association, died at his home on April 28, aged 77 years.

Dr. ADDISON MCARTHUR BOURLAND of Van Buren, Ark., a graduate of the Medical Department of the University of Tennessee in 1857, died at his home on April 23, aged 87 years.

Dr. ROBERT WATTS EASTMAN of New York, a graduate of the College of Physicians and Surgeons, Homeopathic, Buffalo, in 1879, and a member of the Greater New York Medical Society, died at his home on May 5, aged 60 years.

Dr. ARTHUR AMES BLISS of Philadelphia, a graduate of the University of Pennsylvania, Department of Medicine, in 1883, for twenty years laryngologist at the German Hospital and the Mary J. Drexel Home, and a member of the Pennsylvania State and Philadelphia County Medical Societies, the American Laryngological Association, and the Section on Otology and Laryngology of the College of Physicians of Philadelphia, died suddenly at his home on May 2, aged 54 years.

Dr. BENJAMIN BARR of Burlington, N. J., a graduate of the Homeopathic Medical College of Pennsylvania, Philadelphia, in 1855, a veteran of the Civil War, and for many years a practitioner of Philadelphia, died at his home on May 5, aged 85 years.

Dr. FREDERICK L. PRESTON of Chester, Pa., a graduate of the Hahnemann Medical College and Hospital, Philadelphia, in 1877, died at his home from paralysis on April 21, aged 70 years.

Dr. WILLIAM GOMEZ WARD of Mobile, Ala., a graduate of the University of Alabama, Medical Department, Mobile, in 1895, and a member of the Alabama State and Mobile County Medical Societies, died at his home on April 26.

Dr. GEORGE THOMAS CARSON of Chatsworth, Ill., a graduate of the Rush Medical College, Chicago, in 1896, and a member of the American Medical Association and the Illinois State and Livingston County Medical Societies, died at his home from pneumonia on April 25, aged 43 years.

Dr. RUFFIN C. CLAIBORNE of New Roads, La., a graduate of the Medical Department of the Tulane University of Louisiana in 1905, died at his home after a short illness on April 27, aged 33 years.

Dr. JACOB L. NOBLE of Preston, Md., a graduate of the University of Maryland School of Medicine, Baltimore, in 1876, and a member of the Maryland State and Caroline County Medical Societies, died at his home on April 29, aged 64 years.

Dr. GEORGE HANCOCK INGALLS of Boston, Mass., a graduate of the University of Vermont College of Medicine, Burlington, in 1885, and a member of the Massachusetts State and Suffolk County Medical Societies, died at his country ho ne in East Kingston, N. H., after a long illness, on May 4, aged 53 years.

Dr. PATRICK J. TIMMINS of Boston, Mass, a graduate of the Georgetown University School of Medicine, Washington, in 1878, died at his home on May 4, aged 62 years.

Dr. JAMES E. PAYNE of Normangee, Texas, a graduate of the Barnes Medical College, St. Louis, in 1901, died recently in a sanatorium at Houston, Texas.

Dr. GUSTAF BJORKMAN of Racine, Wis., a graduate of the University of Upsala, Sweden, in 1878, and of the University of Stockholm in 1887, died at his home after a long illness on April 27, aged 58 years.

Dr. H. M. CRAWFORD of New York, a graduate of the College of Physicians and Surgeons, New York, in 1896, died at his home on May 7.

Dr. WILLIAM HENRY MEREDITH died at Quakertown, Pa., on May 9, at the age of 70 years. He was graduated from Jefferson Medical College in the class of 1866.

Dr. ARTHUR E. SPOHN of Corpus Christi, Tex., a graduate of the Long Island College Hospital, Brooklyn, in 1867, and of the Bellevue Hospital Medical College, New York, in 1879, died at his home after a short illness, on May 5.

Dr. FRED HOYT PILCHER of Winfield, Kan., a graduate of the Ensworth Medical College, St. Joseph, Mo., in 1893, and formerly superintendent of the Kansas State School for the Feeble Minded, died recently, in Eureka Springs, Ark.

## OUR LONDON LETTER.

(From Our Regular Correspondent.)

ROYAL MEDICAL FUND—YELLOW FEVER COMMISSION—PLAGUE COMMITTEE REPORT—ANKYLOSTOMIASIS—NURSES ASK FOR REGISTRATION—BIRMINGHAM HEALTH WEEK—CONGRESS—OBITUARY.

LONDON, May 2, 1913.

THE Royal Medical Benevolent Fund held a dinner on Wednesday to celebrate the fact that the prefix "Royal" was added to its name by permission of the King, who has consented to become patron of the charity. Prince Arthur of Connaught had promised to preside on this occasion, but was prevented by the grave condition of his mother, the Duchess of Connaught. Sir John Tweedy took the chair and read to the company the draft of a speech which the Prince had sent to him to signify what he had hoped to say. It contained a sympathetic acknowledgment of the benefits the royal family had received from the noble profession of medicine and alluded to the crisis from which his mother was being restored, but which on that date the relapse had rendered inappropriate.

The Yellow Fever Commission differs somewhat from the bodies usually so termed and is rather a committee of experts for examining and reporting on investigations made for it by competent persons in West Africa. In 1909 an advisory committee was set up in consequence of Professor Simpson's investigations, to advise the Colonial Secretary on the medical and sanitary conditions of tropical Africa. Very soon afterward a sanitary department was at work in the West African colonies, for each of which an expert was appointed. The results of its work are most encouraging. The "white man's grave" is no longer a phrase applied to these parts. The death rate among European officials has of late been not much higher than in some English localities. In 1905 it was 28 per 1000 and in the next three years fell to 21 and 18, rose to 20 again in 1910, fell to 14 in 1911 and to 12 in 1912. These are the figures for the full body of officials, above 2,400 in number, scattered over Gambia, Sierra Leone, the gold coast and Northern and Southern Nigeria. Even more encouraging is the diminution of invaliding; in 1904 there were 67 per 1,000; in 1908 they fell to 46, in 1910 to 39, in 1911 to 37, in 1912 to 28. It should be stated that officials now sent out are required to undergo a course of instruction at the Imperial Institute so that they are equipped with a knowledge of the sanitary conditions they may have to meet. The commission mentioned above consists of Sir J. K. Fowler, Major Sir R. Ross, Sir W. Leishman and Professor W. J. R. Simpson, and to some extent their appointment is due to the recommendation of the advisory committee and the controversy on the views of the late Sir Rubert Boyce, who went to Africa in 1910 to inquire into the simultaneous outbreak of yellow fever in Sekondi and Freetown. You will remember that he believed he had traced the disease to a mosquito and held that the insect could be exterminated or "easily tackled," as he put it. Further he concluded that the fever was always endemic among the natives in a mild form and this had been confused with malaria. Many deaths on the coast attributed to malaria had, he felt certain, been due to mild yellow fever, the "disease of the newcomers," as the natives called it. Discussion of this view was unhappily interrupted by his death in 1911, but is again being renewed and will claim consideration from the commission, which is to examine and report on the work now being carried on in Freetown, Acera and Sekondi by a special staff including officers of the R. A. M. C., the West African medical staff, the Lagos Medical Institute and the London School of Tropical Medicine. Most of the members of this special staff are already on the coast. Besides their own individual work, they will seek the co-operation of resident government medical officers and any other medical gentlemen practicing in West Africa. The details and results of their observations and inquiries they will forward to the commission in this country.

The plague investigation committee, in their seventh report, state that in the city of Madras plague has never gained a foothold, except in one epidemic in 1905-6. Yet there is much overcrowding in some of the Indian quarters of this city of 509,346 inhabitants. The corporation has for some years offered a reward of one farthing for every rat brought in, with the result that since 1906 (February), 1,220,686 have been destroyed. Statistics are given showing that in Madras there is a seasonal fluctuation in the number of rats and rat fleas. Neither were so abundant as in other infested places in India, but there were probably plenty to maintain plague if introduced, though possibly few enough to render implantation difficult. From statistics of the disease in man and in rats in Bombay, 1907-11, the collection of rats had been carried out on a large scale by the Health Department of Bombay and careful examination made. It appeared that the rat epidemic always precedes the human. The mice of Madras harbor fled from fleas. The report contains articles on chronic or resolving plague, on serum treatment, on experimental production of plague in rats, on the immunity of the wild rat in India and on flea-breeding in Poona.

Ankylostomiasis was supposed not to be prevalent in Grenada, but Dr. Cockin, who has been in charge of hospitals there and now returned, reports in *Parasitology* over 80 per cent. of hospital patients suffered from it. To get rid of it he recommends incineration of sewage, compulsory use of boots for laborers on land, application of lime to infected ground, leaving sufficient space between rows of trees, drainage, and free dispensaries. A pretty full list of requirements, but if all these methods were vigorously resorted to Dr. Cockin thinks the disease would be eradicated.

Nurses are making another attempt to secure state registration. On Monday the Prime Minister received at the House of Commons a deputation from the central committee, which represents some half dozen societies engaged in the effort to set up a register of trained and qualified nurses and so enable the public to distinguish them from the untrained and unqualified. Dr. W. A. Chapple, M. P., introduced the deputation and told the Premier that two vested interests were opposed. One the unqualified, the other one or two hospitals which exploited nurses for their own financial advantage. He declared trained and skilled nurses as necessary as medical men and untrained ones as dangerous as unqualified doctors. He did not ask any exclusive rights, but only a means of distinguishing those who were qualified from those who were not. Sir V. Horsley supported the proposal, as he said, on behalf of the British Medical Association, which he asserted was the only society which could be said to

represent the medical profession. This is rather a large claim, considering that though on this question it may do so, on others it has sometimes misrepresented the prevailing opinions. Drs. Mackintosh and McGregor addressed the Premier, as did three ladies, who dwelt on the project as it affected the public.

In his reply Mr. Asquith said he was much impressed by the arguments put forward, but thought Dr. Chapple took too sanguine a view of the opposition to their proposals, which was more formidable than four years ago, when he received a similar deputation. This opposition, he was informed on the best of authority, was now taken part in by 91 chairmen and 66 matrons of London hospitals, 178 matrons of provincial hospitals, 1,332 nurses and 342 doctors. He must say, in view of the figures, there was not unanimity among doctors or nurses for they must count matrons as among the most skilled.

He thought such a measure as they proposed would be vigorously opposed in parliament. He was not expressing hostility or even want of sympathy, but suggested they should negotiate with their opponents or so modify their plans as to command the support of the medical and nursing professions. If they would do that the Government would ardently sympathize—cold comfort, perhaps, but all he could give at present. Dr. Chapple said they had got unanimity among the societies, but could not possibly do so among individuals. He complained of the action of one hospital as to their nurses and the Premier said he would communicate the statement to the chairman.

This is Birmingham Health Week and has been kept with the usual spirit of the Midland capital. It opened on Sunday with sermons in about 150 churches and chapels in the city. Besides the leaders of various organizations for the betterment of the people, the Lord Mayor, the Medical Officer of Health and the Health Committee, the vice-chancellor of the university and chairmen of the several hospitals and an array of medical men and other speakers have been actively engaged all the week in pushing the claims of civic hygiene. A pamphlet has been issued showing what ought to be done in clearing away slums and many addresses have dwelt on the housing of the poor in the central and older parts of the city. Numerous public meetings in the Town Hall and the various council schools have been held daily.

The arrangements for the International Medical Congress in London from the 6th to 12th of August next are well advanced and the twenty-three sections all promise to be interesting.

Dr. William Huntley, superintendent of the Agra Medical Missionary Institution, died on the 11th of April in his fifty-fourth year. He had passed nearly all his medical life in India as a medical missionary and his services in several districts as such and in times of famine were greatly appreciated. In 1902 he took up the important post at Agra, where native Christians were trained for hospital assistants. He was educated at Glasgow University and took the degrees of M. A. and B. Sc., as well as the bachelorship of medicine and surgery followed by the M. D.

Dr. S. W. Cheeham, a well known practitioner of Forest Gate, died suddenly on the 27th of April, aged 49, while on a visit to a patient to whom he had hurried on his tricycle.

## OUR LETTER FROM THE PHILIPPINES.

(From Our Regular Correspondent.)

DISPOSAL OF EXCRETA—THE HOG AS A CARRIER OF HUMAN INTESTINAL DISEASE—MINNOWS AS DESTROYERS OF MOSQUITO LARVÆ—PLAGUE-INFECTED RATS.

MANILA, P. I., March 15, 1913.

IN order to deal more intelligently with the problem of the disposal of human excreta in the provinces, where no water carriage of sewage is practicable, and for the purpose of ascertaining whether the hog, which is the universal scavenger in the Philippines, might be concerned in the transmission of diseases to human beings, the Bureau of Health has had an interesting series of experiments made by the Bureau of Science, and these have just been completed.

The intestinal discharges of pigs were found to contain an entameba which closely resembled the pathogenic entameba of man, but this was finally determined not to be identical with the *Entamœba histolytica*. Four young pigs, used in the experiments, were naturally infected with human stools containing many encysted *Entameba histolytica*, and these were mixed with boiled rice and fed to the pigs. Daily stool examinations, which were begun the day of the feeding, were made for a period of 58 days. They constantly showed cysts of the pig entameba, but never the *Entameba histolytica*. Attempts were then made to infect monkeys with the pig entameba, but these experiments resulted negatively.

Feeding experiments were then made with hookworms which were obtained by making cultures of human feces containing the eggs of the hookworm. A pig was then fed on a six-day culture, an eight-day culture, a thirteen-day culture, and a fifteen-day culture. Stools of this pig were examined daily for a period of two months, with negative results.

Seven monkeys were then fed feces of a pig which contained many encysted balantidia and these were mixed with rice and fed to the animals. One monkey received direct rectal injection of the fluid stool from a man, containing many motile balantidia. The immediate result of these feeding and injection experiments appeared to be negative. However, by following the cases with daily stool examinations, and ultimately by necropsies, it was found that every one of the experimental animals became infected, that is to say, the pig-balantidia behaved in the monkey like the *Balantidia coli* does in man, it only appearing in the stools at rare intervals. In two of the cases they were never found constantly in the stools until the necropsies were made. Monkeys that were killed one month after the feeding experiments were begun, showed portions of the large intestine congested and reddened, but there were no ulcerations present. Sections of such areas showed the balantidia penetrating the sound tissue into the submucosa as far as the muscularis.

From the foregoing it was concluded that the pig-balantidia is identical with the *Balantidium coli*, and the primary etiological agent in balantidial dysentery of man. The experiments with *Strongyloides stercoralis* resulted almost identically with those of the *Balantidia coli*. The conclusions deduced from all of the experiments were, that the domestic pig plays no rôle in the dissemination of amebic dysentery or hookworm infection, but that it may be the source of infection in man of *Balantidia coli* and *Strongyloides stercoralis*, in the Philippine Islands.

In order to ascertain whether the pig in the Philippines is concerned in the dissemination of cholera, and especially whether the pig may not be an important agent in aiding in the suppression of cholera, a number of experiments were carried out. A hog was fed on rice mixed with a 24-hour old agar culture of cholera vibrio, at 8:45 in the morning, and the rectum was swabbed a day later and the specimen planted in 300 c.c. of cholera peptone the following morning. The peptone culture was examined by the hanging drop method, and found to contain a motile organism. It was then plated on Dieudonné's medium, and on lactose litmus agar. The following day the rectum was again swabbed and cultures made, and these were examined by the agglutination test with anti-cholera serum, but no positive reaction resulted. On the fourth day, plates and peptone cultures of the third day were examined, but no cholera vibrios were found. These experiments were repeated a number of times, and finally cholera cultures were injected into the rectum of the pig and high rectal enemas were given. In some of the experiments cholera cultures with rice were given in connection with sodium carbonate, with the view to neutralizing the hydrochloric acid of the stomach; the results were, however, negative.

Similar experiments were carried out with the *Bacillus dysenteriæ* of Flexner, and the results were practically identical with those of cholera, although in one instance, in which sodium carbonate was given, an agglutination was obtained.

The conclusions reached were, that the experiments directed to make hogs carriers of cholera vibrio and bacillus of dysentery met with negative results, as the attempt to recover the bacteria in question always resulted negatively after a period of 24 hours.

After considerable difficulty, Mr. A. Seale, of the Icthyological Section of the Bureau of Science, finally succeeded in importing some top minnows (*Gambusia affinis*) from Honolulu. These are now being used by the Bureau of Health in the swampy lowlands around Manila. In the experiments which were conducted in the laboratory, these minnows consumed enormous numbers of all forms of mosquito larvæ that were placed in the tanks with them.

Until recently, the rat campaign which has been conducted in the city of Manila has only resulted, at the rarest intervals, in the finding of plague-infected rats, in spite of the fact that a careful autopsy was made of each rat, and cultures made from all those that were doubtful. The number of rats caught frequently amounted to more than 7,000 per month. Within the past week, however, there has been a decided increase in the number of plague-infected rats found, no less than four having been encountered in as many houses. Three of these were in the Tondo district. An investigation made of the premises at 319 Estero Cegado, from which the first of these rats came, showed them to be a bottling establishment in which wine, olives, pickles, etc., are placed in bottles and then packed for shipment to the various parts of the Philippines. The empty bottles and the straw containers used to pack them in order to prevent breakage, were imported from Osaka, Japan. Human, or rat, plague has been more or less constantly present at Osaka during the past five years, and it has been assumed that plague-infected rats or fleas may have been imported with the straw.

Another plague-infected rat was found at 204 Calle Concha. An investigation showed that this address was a tenement house only recently completed, and built in accordance with modern rat-proof construction. A careful inspection did not reveal any rat-breeding places at number 204, but at number 200, which is in the same house, it was found that one of the tenements was used as a bottling place for soft drinks which are sent to the provinces. These are packed in identically the same straw containers which are mentioned above and are obtained from Japan. An investigation of a bale of containers resulted in the discovery of twenty-eight rats, none of which showed any evidence of plague infection by autopsy. A curious incident in connection with the rat plague is the fact that so far no rats dead of plague have been found. All of the rat plague has been among animals that were either trapped or poisoned. It is also a noteworthy fact that the first rat caught at 204 Calle Concha should be plague-infected and that the next twenty-eight caught in the same premises should be free of the disease. This gives another instance in which it might have seemed, at first, that the rat-proof construction was at fault, whereas, the difficulty lay with the quality and kind of material which was stored in the rat-proof house. The rats in question were easily killed, and afforded a most striking example of the ease with which rats can be destroyed provided the building offers no harboring places for them.

The rat plague-infection seems to be heaviest in the Tondo district. Fifty extra men have been employed by the Bureau of Health to aid in the destruction of rats, and particularly the rat nests, especially where they are in close proximity to man.

7. Non-Union of the Clavicle in a Child. W. P. Coues.
8. A Case of Blood Cyst of the Chest Wall. W. P. Coues.

1. **Diagnosis of the Tuberculous Nature of Joint Disease.**—E. G. Brackett outlines the following as characteristic signs of the tuberculous nature of an arthritis: The affection is almost always monarticular, and if it involves a second joint, the process in the latter follows tardily on the first, is much less severe, and of a less destructive course. The development of a tuberculous arthritis is slow, extending over a period of months or years. Remissions are usual, but during them the disability never entirely disappears, and there are one or more of the following residual symptoms: deformity, limp, slight disability, and swelling. Pain is not a prominent symptom. During the attacks pain is most noticeable as sensitiveness, and disappears with the acuteness of the attack. Fluid in the tuberculous joints is not usual, unless it be pus, and this naturally occurs as a late symptom, and when destruction has already begun and when the diagnosis is no longer in doubt. The swelling in superficial joints has much the feel of fluid, but is due to the thick, vascular, velvety synovial membrane which gives an elastic feel closely resembling that of fluid, and varies with the vascularity. A rise of temperature is not to be expected in the slowly developing and quiet joints.

2. **Infantile Beriberi in the Philippines.**—D. Gregg

concludes from his investigations that infantile beriberi in the Philippines is a nutritional disease which occurs among native breast-fed infants. It causes about 25 per cent. of the total native mortality in the city of Manila. It is due to the absence of some, as yet unknown nutritional substance in the breast milk of the nursing mother. It has been successfully treated by the giving of an extract of rice polishings, which is believed to supply the nutritional substance absent in the mother's milk. In the Philippines, where babies are almost always of necessity breast-fed, the reduction of the infantile mortality is dependent, even more than in other countries, upon the care and proper nourishmnet of the nursing mother.

3. **Gestational Cholecystitis and Cholelithiasis.**—R. M. Green refers to a definite causal association of cholecystitis and cholelithiasis with pregnancy. Symptoms due to either of these conditions may occur during pregnancy, during the puerperium following labor at term, or after miscarriage. The existence of gall-bladder disease is not in itself a cause of miscarriage, but miscarriage may induce the development of active symptoms from a process previously latent. Cholecystitis or cholelithiasis occurring during convalescence from miscarriage should receive the same surgical treatment and bear the same prognosis as in cases not associated with pregnancy.

4. **Subdural Lipomatosis of the Spinal Cord.**—S. B. Wolbach and J. H. P. Millett state that subdural lipomata are not uncommonly seen in cases of spina bifida and spina bifida occulta. Von Recklinghausen has shown the significance of these tumors, and has called attention to the fact that they are almost invariably mixed tumors, rather than true lipomata: usually myolipomata or fibrolipomata. These mixed tumors either spring from the subcutaneous tissue and stretch toward the cystic myelomeningocele, or are true intradural growths, springing from the spinal membranes and projecting free into the cyst. Fatty tumors may also appear when there is no marked cystic enlargement of the spinal canal, but only a flattened serous canal, the remains of a shrunken cyst that had formerly existed over the sacral region. It is noteworthy that in such cases clubfoot, a symptom so often associated with spina bifida, has occasionally been observed. Cases of intradural lipomata not connected with spina bifida are, on the other hand, extremely rare.

5. **Abuse of X-Rays in Dermatology.**—J. T. Bowen notes that a great many cases of unnecessary disfigurement, more obvious than the original affection, are caused by an improper use of the *x*-rays. The cases suitable for this treatment can be selected only by those who have considerable knowledge of skin affections. This method of treatment requires especial study and training and should not be regarded as an easy and safe procedure by those unskilled in its use.

6. **Remissions in Paresis.**—H. L. Paine finds from a study of unselected and consecutive cases of general paralysis admitted to a hospital during a period of thirty-four years that only one case with a history of a paralytic seizure showed a remission, and only six cases with a history of any form of cerebral insult showed a remission. Inversely, then, it may be said that if a case of general paralysis in its early stage has a paralytic seizure, the chances are very small that that case will have a remission.

7. **Non-Union of the Clavicle in a Child.**—W. P. Coues reports the case of a girl eleven years of age who five weeks after the receipt of an injury resulting in fracture of the right clavicle, still showed no real bony union at the site of fracture but only soft callus. There was a persistent slough over the olecranon resulting from the pressure of a modified Sayre dressing. *X*-ray examination of the child's leg bones showed a well-marked periostitis of the tibiæ. This indicated a syphilitic cause for the failure of bony union. Mixed treatment resulted in rapid improvement, and in six weeks the clavicle was practically solid.

12. Biostatistics of the Jewish Race. L. Levyn.

1. **Insane Aliens.**—G. W. Stoner states that a more careful inquiry into matters pertaining to the medical office or the Immigration Service proper at Ellis Island would probably convince any fair-minded person that remarkably good work is being done there, in behalf of the immigrant as well as for the good of the State, but all agree that the space now occupied as medical examination rooms should be largely increased, that the number of medical officers should be at least doubled, and that a sufficient force of interpreters should be employed to meet all requirements; also that in the question of deportation no limit as to length of residence in this country should apply to any defective or otherwise excludable unnaturalized immigrant.

3. **High Tension, High Frequency Currents.**—By J. H. Branth. (See MEDICAL RECORD, March 22, 1913, page 547.)

4. **The Wassermann Reaction.**—G. A. Wyeth calls attention to the fact that the Wassermann reaction is not a test for the presence or absence of the exciting cause of syphilis, but is a test for the *antibodies* of this cause. This is shown by the fact that the Wassermann reaction is seldom positive in a fresh case of syphilis until toward the end of the first month after infection, that is, until the antibodies have had time to form. Verification of the clinical diagnosis in the first few weeks, therefore, is better made by examining scrapings from the depths of the suspected lesion under dark field illumination for the *Treponema pallidum*. In secondary, untreated, tertiary, and florid hereditary syphilis, and in paresis the percentage of positive reactions is very high, while in latent hereditary syphilis and in tabes dorsalis the author has been unable to obtain a positive reaction from the blood in more than fifty per cent. of the cases. In treated tertiary cases the reaction varies greatly, depending upon the amount of treatment previously administered, the date of the last treatment, etc. In syphilis of the cerebrospinal axis, and particularly in tabes dorsalis, the cerebrospinal fluid should be examined, for a positive Wassermann reaction may be present in this fluid even though absent from the blood. By way of preliminary precautions, one should bear in mind that a positive Wassermann reaction may occur in recent malaria, yaws, and leprosy; that alcohol taken in considerable quantities may mask an otherwise positive Wassermann reaction by rendering it negative; and that antisyphilitic therapy, when given in sufficient doses, generally renders the reaction negative, so that it is well to suspend all treatment for from three to six weeks before having the reaction made.

6. **Eyestrain in General Practice.**—By I. Hartshorne. (See MEDICAL RECORD, April 22, 1913, page 685.)

8. **Hospital Prophylaxis.**—L. D. Frescoln makes a plea for the maintenance of ideals in hospital work, which should represent the most advanced medical thought pertaining to all bodily states. Every precaution should be taken to prevent hospital epidemics; accidents should be carefully guarded against. Every individual connected

with the hospital should know how to prevent and extinguish an ordinary fire. There should be a careful choice of the anesthetic used, and economy may be effected in the less lavish use of the latter. All safeguards should be taken against the possibility of mistakes in the giving of medicines. Systematic regulations requiring proper ventilation, proper bathing, boiled water, pure foods, and graduated exercises all go to keep the institution as a whole in a state of less vulnerability than would otherwise exist. Points of seeming insignificance are to be borne in mind, such as the early outfitting with screens and killing of flies to prevent spreading of noxious diseases; removal of garbage and material upon which germs breed; the control of visitors to prevent bringing in contagions; and the control over the house staff to get prompt, serious, and efficient service.

10. **Tuberculosis of the Liver with Jaundice.**—L. S. Milne states that tuberculosis of the liver occurring in the course of general acute miliary tuberculosis, or secondary to tuberculous disease of the lungs or intestines, is by no means uncommon. It may indeed be very extensive, the liver being crowded with tubercles, yet only rarely is it of sufficient degree to be associated with jaundice. Still less common are those cases in which the liver is the only, or the most affected organ. The condition of jaundice produced by tuberculosis of the liver does, however, occasionally occur. The clinical picture seems to be fairly definite, although it has received only very scant attention in the literature of tuberculosis. The author records two cases, in which there was severe jaundice and in which the liver was the seat of extensive tuberculosis. The physical signs which were manifested were chiefly referable to the liver, yet the true condition responsible for the jaundice was not recognized during life in either case.

11. **Use of the Duodenal Tubes.**—L. A. Doroff enumerates and describes the following diagnostic and therapeutic uses of the duodenal tube: the differentiation between duodenal and pyloric stenosis; the diagnosis of duodenal ulcer; the diagnosis of duodenitis; transduodenal lavage; duodenal alimentation; the introduction and local application of remedies; the introduction of oxygen into the intestine for antiseptic purposes; the relief of persistent flatulency by the removal of gas from the duodenum.

9. Pellagra: Some Facts in Its Epidemiology. R. M. Grimm.

1. **Devices for Artificial Respiration.**—S. J. Meltzer recalls the fact that in a preliminary note about a year ago he described a simple method of artificial respiration by means of which air was driven rhythmically by a bellows through a tube introduced into the pharynx. While this proved effective in dogs, rabbits, cats, and monkeys it failed in human beings, since in them the pressure on the superhyoid region did not sufficiently restrict the escape of air through the mouth and nose. In the present article the author describes two methods of causing the rhythmic introduction of air into the lungs in man and even in the rigid or frozen cadaver. He calls these methods the pharyngeal and mask devices. In the case of the first method the apparatus consists of a metal pharyngeal tube, a respiratory valve, a foot bellows or oxygen tank, and a safety valve; and, as accessories, a tongue forceps, a stomach tube, heavy weights and a belt. The heavy weight is placed on the abdomen to prevent the entrance of air into the stomach to any great extent and the belt is used to reinforce the pressure. When for any reason the weight cannot be used, a stomach tube of large diameter should be passed through the esophagus into the stomach for the escape of air. The pharyngeal end of the tube is shaped so as to fit into the pharynx, but a hole is provided for the stomach tube if needed, which can be closed by a movable plate. With the mask method every other part is the same as in the pharyngeal tube, except that instead of introducing a tube into the pharynx a well fitting mask is tied to the face. It is more especially suited for emergency cases than the pharyngeal method. The devices can be readily combined with the Schafer method of manual artificial respiration and are simple and inexpensive. While the use of the pharyngeal method requires some training, the mask method is so simple that laymen can be intrusted with its use.

2. **Carbohydrate Treatment in Diabetes.**—H. Strauss states that the oatmeal treatment does not act by virtue of any special property of oatmeal different from the properties of other flours. Under the same conditions of a diet without meat and with only a small amount of albumin, wheat flour does equally well. In the reduction of the quantity of albumin the author does not go as far as Blum, and for long periods of treatment he recommends not less than from fifty to sixty grams. A certain quantity of carbohydrate agrees with the diabetic the more slowly it is absorbed. In grave cases the author recommends inulin, especially for those with acidosis. It is clear that a carbohydrate treatment can be used only periodically and then only in grave cases, the lighter cases being treated on the old and tried principles. The later researches have shown that among grave cases there are those which are sensitive to albumin and, in these at least, the old method of giving unmeasured quantities of albumin is wrong. It is of special importance to know that in grave cases meat endangers the tolerance. It has also been proved that a certain scarcity of calories is useful; twenty-five calories per kilogram is sufficient for many diabetics. The carbohydrates of plants are slowly absorbed, thus favoring tolerance, and it may be that the intestinal flora is also favorably affected. It must be noted, however, that not every form of vegetable diet is suitable; it must be poor in carbohydrates and rich in fats, and those carbohydrates must be preferred for which the patient has the greatest tolerance.

4. **Tuberculosis of Large Arteries.**—S. R. Haythorn states that four types of tuberculous lesions of the aorta and its main branches have been described: (1) miliary tuberculosis of the intima; (2) polypi of tuberculous tissue attached to the intima; (3) tuberculosis of the wall, involving the several layers; and (4) aneurysms, the walls of which are composed of tuberculous tissue. The first is by far the most common, usually alone but sometimes combined with the other types. Under the third type are included all the tuberculous lesions affecting the several layers of the wall. Of the fourth and the last group the author has been able to find only four cases on record and these are noticed more fully for the purpose of comparison with the case he reports himself.

5. **Treatment of Felons.**—G. M. Dorrance describes his method of treatment as follows: The incision starts at the level of the base of the nail on one side and extends in the line of the skin furrows over the tip of the finger, up the opposite side to a point on the level with the beginning of the incision, in that way making a flap of the tip of the finger. A piece of rubber tissue or gauze impregnated with petrolatum is placed in the uppermost angle of the wound. The wound is dressed in normal salt solution and the dressings, which are kept moist, are renewed each

day. The rubber tissue will come away about the third day and no subsequent packing will be needed. A general anesthetic is advised, preferably nitrous oxide.

6. **Later Histories of Four Surgical Cases.**—W. W. Keen describes the later histories of four surgical cases. One was his first case of modern cerebral surgery in which he removed, in December, 1887, a large tumor from the brain. The patient is still living at the age of 50 years and bids fair to live for some years more. His sight is poor, but he can find his way about and he has an epileptic attack about once a year. Two cases are of cancer of the rectum, in one of which 6 inches was excised and in the other 9½ inches. The first patient lived fourteen years and died without known recurrence. He was able to enter into business and social life as before. The second patient is still living with an inguinal anus which causes little inconvenience, and he gives the details of the method of dressing which is attended to by the patient himself. A "dummy" truss suggested by this patient has been of great service in other cases. The last patient was a naval officer who had a traumatic rupture from the middle meningeal artery. After trephining, nine tablespoons of blood were removed. The patient made a perfect recovery and was in excellent condition six years after the accident when he was killed by an explosion on the vessel on which he was serving.

9. **Pellagra.**—R. M. Grimm concludes from his observations that more cases of this disease develop among the whites than among the negroes. More cases occur among the females of both races than among the males. More cases develop between the ages of 20 and 40 years than at other ages. Among the married and widowed pellagrins the females predominate; the single pellagrins are equally divided between the sexes. More of the author's cases had their onset during the months of May and June than in other months, and more in 1911 than in any previous year. More cases developed under conditions of poverty than of comfort, and more under conditions of comfort than of affluence. More cases developed in the vicinity of other cases than otherwise. None of the facts seems to indicate that pellagra is hereditary. The food used by the people in whom pellagra is prevalent deserves consideration as a possible etiological factor. The most promising field for the investigation of the etiology of pellagra is the food being used by the people in whom pellagra is developing.

6. Protozoal-Like Structures in the Blood in a Case of Black-Water Fever. A. C. Coles.
7. Man's Mental Evolution, Past and Future. H. Campbell.

1. **Birth Palsy with Subluxation of the Shoulder-Joint.**—H. A. T. Fairbank notes that subluxation of the shoulder-joint has received very little attention as a result of birth paralysis. In the treatment of the latter condition the most important measure is to obtain relaxation of the paralyzed muscles. If the joints of the paralyzed limb are placed in the correct position and if massage is ordered, nature will do the rest unless the nerve lesion is beyond recall. The author uses a special splint which is designed to keep the arm abducted to a right angle at the shoulder, with the forearm at a right angle with the arm, and the forearm supinated. The splint is taken off at least twice daily for massage of the whole arm and shoulder and passive movements of the joints. If after three months' careful treatment there is no sign of recovery the muscles should be treated electrically under an anesthetic, and if they do not respond to faradism operation upon the plexus is advisable. If subluxation of the shoulder-joint is present the reduction should be effected according to the method recommended by Royal Whitman.

3. **Radium Emanation Therapy.**—W. Engelmann states that radium emanation has an intensely stimulating effect on all the factors of assimilation. The emanation may be administered by means of baths, inhalation, drinking, enemata, or compresses. The diseases in which this form of therapy is useful are the following: Gout, articular rheumatism, sciatica and other forms of neuritis and neuralgia, bronchial asthma, arteriosclerosis, chronic pelvic exudates in the pelvis in women, etc.

5. **Treatment of Confirmed Cases of High Blood Pressure.**—A. Mantle quotes Oliver as follows: "The fact should be emphasized that supernormal arterial pressure is not itself a primary condition to be attacked or controlled as such. It is invariably a result of some pathological cause or causes, and it is, moreover, often a necessary evil the result of conditions we cannot remove, and then it must be looked upon as a compensatory effort, as one of the natural defences of the body." The author proposes the question: How is one to determine the true position of a case of supernormal pressure? There are two dangers: with one eye one sees visions of a possible catastrophe through the rupture of a weak vessel by doing too little, and with the other the danger of doing too much in lowering the pressure and weakening the cardiac force. The author's reply to the above question is as follows: One should take a careful history of the case and observe the condition of the cardiovascular, the renal, and the alimentary systems, and try to find out the cause of the high pressure, such as errors in diet, alcohol, syphilis, lead, and excessive worry, remembering that supernormal pressure is not a disease *per se*, but a symptom only. If the left ventricle is hypertrophied, it suggests that the pressure has been persistently high for some months or years. Experience teaches us that with a restriction of red meats and alcoholic drinks from the dietary of those who take them freely the pressure, if not a permanently high one, usually diminishes, and this argues that purin bodies and alcohol probably act as vasoconstrictors. Waste is constantly going on in the body, and it is important to get rid of the products of waste whatever they may be. The proof of the splanchnic vessels being some of the earliest to become affected in arteriosclerosis suggests that one should relieve the congestion of the visceral vessels, which can be done by judicious purgation. One-gram doses of calomel and saline purgatives are most useful two or three times a week. One of the greatest outlets for waste products is the skin, and when inactive a free action of this organ must be encouraged by artificial means, such as by massage-douche and Nauheim baths, when these can be obtained, and intestinal lavation is also very desirable in cases with constipation. It is a common observation that with a dilated periphery causing an active skin there is a lower range of blood pressure, which leads one to suggest to those who can afford it to follow the sun. If in spite of all régime and treatment the pressure continues high after the case has been watched carefully for some months, one concludes that this is a case in which the pressure is permanently supernormal. In any event the general régime should be continued, and as long as no urgent symptoms arise the patient may do his work in life if he avoids excitement and sudden strain. Lastly, one must not use any active means to reduce the pressure, remembering that it is probably an advantage and necessary that the pressure should be high for the maintenance of an adequate supply of blood to vital organs. As for drugs of the vasodilator type, the nitrite group, I use them

very little except in emergencies, for the author believes it is sounder treatment to get rid of the bodies in the system which contract the periphery by the means he has mentioned, rather than by dilating the blood-vessels with the offending poisons still intact. He gives iodides very carefully, if at all, but if there is any syphilitic history they may be pushed.

7. Removal of Intrathecal Tumor from Lumbar Region of Spinal Cord. J. M. Clarke and C. A. Morton.
8. Classification of Tumors of the Pituitary Body. Gerhardt von Bonin.

1. **Tuberculin as a Specific Cure.**—H. Batty Shaw believes it is certain that if any remedy were applied to cases of pulmonary tuberculosis, some of the individuals would get better after its use. The same may be said of tuberculin. There have been many series of cases reported in which it is said there is evidence that tuberculin is a specific cure. Bandelier has published results of tuberculin treatment; he found that 100 per cent. of the cases in Turban's first stage lost their tubercle bacilli; 87 per cent. of the cases in Turban's second stage, and 44.2 per cent. of the cases in Turban's third stage also lost their tubercle bacilli. The total cases treated numbered 202. One has a right to ask, What would such cases have done without tuberculin? It is right to object that the disappearance of tubercle bacilli from the sputum is too often but a temporary phenomenon. Like all vaccine treatment, tuberculin is certainly capable of effecting a change in the aspects of the disease. Put it has never been experimentally proved that such changes are curative; the alleged curative changes can be explained on anaphylactic grounds.

3. **Prognosis in Pulmonary Tuberculosis and Arneth's Method.**—J. B. H. Holroyd notes that the prognosis in pulmonary tuberculosis is of vital importance both to the patient individually and to the health of a community. To make a correct prognosis is in many cases very difficult, and in some cases is almost impossible if physical diagnostic signs are the only guides available. Arneth's method of blood counting offers, however, some solution of the difficulties encountered in this connection. When Arneth devised this method he took the neutrophilic leucocyte, which may have I, II, III, IV, or V nuclei, as the cell, and on this he made his count. He then assumed that the cells with I or II nuclei were less resistant than the cells with III, IV, or V nuclei and that when those less resistant cells were present in large numbers the severity of the case varied directly as the number of these cells. The author adopted this method and applied it to thirty cases extending over a period of three months. The observations made on these cases suggested that Arneth was right, and that the prognosis varied inversely as the increase in neutrophiles having I or II nuclei.

4. **The Epiglottic Suture.**—C. Horsford regards the preliminary use of the epiglottic suture for facilitating intralaryngeal operations as not limited to cases of obscured field of operation caused by a markedly overhanging epiglottis. This procedure should be used in all cases in which the epiglottis in any way hinders a delicate intralaryngeal manipulation, whether it be cutting or cauterizing, especially where a perfect vocal result is desired. This method may also be used simply for diagnosis, when other methods of lifting the epiglottis have failed. It may in a few cases be used without the aid of a laryngeal mirror, when it is found, on depressing the tongue, that the upper border of the epiglottis can be seen.

5. **"Cheilotomy."**—W. Sampson Handley and C. Preston Ball present a preliminary communication on an operative method which may prove to be of wide application in the treatment of chronic hypertrophic arthritis, especially if it be uniarticular and of traumatic origin. It is a record of the two first cases in which the method has been applied. Both were of traumatic origin, and in both the hip was the joint affected. In both, while flexion remained relatively free, the movements of abduction and rotation were lost, so that riding was impossible and walking was slow and difficult. In the first case continuous severe sciatic pain, dating from the accident, made the patient's life a misery to him. Stereoscopic radiograms showed clearly that the principal obstacle to the movements of the joint in both cases was an osteoarthritic lip or cornice around the head of the femur. It occurred to one of the authors that it might be possible to chisel away this lip sufficiently to relieve pain if not to restore a useful range of movement to the joint. An operation for this purpose was devised and successfully carried out, with functional results in both cases which up to the present have surpassed the authors' expectations. The operation consists in opening the hip-joint and removing the cornice on the head of the femur, so far as it is accessible, by suitable bone-cutting instruments devised to work in a cramped space. On account of its technical difficulty the operation is somewhat prolonged, but in both instances shock has been absent and convalescence uneventful. It will probably be found that this operation is applicable in other joints than the hip. A procedure so definite, and possibly of such wide application, appears to need a distinctive name. The authors suggest the name *cheilotomy* (χεῖλος, lip) as convenient.

## Berliner klinische Wochenschrift.

*April 21, 1913.*

**High Altitudes and the Pulse Frequency.**—Stern deals with mountain climbing as well as rarefied air. The height above sea level in the experiments cited was from 5,000 to 8,000 feet. It was ascertained that descending requires nearly as much effort as climbing mountains if the subject is on his feet. He is engaged constantly in actively lowering the same weight which he has been lifting. The steeper the incline the greater the effort in descent. Naturally for the purpose of comparison the same rate of speed must be maintained in both directions. The only advantage in descent is that friction is somewhat diminished. To give a concrete example the pulse of one of the party, male, was 92 at the height of 1,750 meters. Four hours later, at 2,600 meters, it was 126. After a brief rest at the summit the pulse increased to 132. Descent now began and at 2,150 meters the pulse had risen to 136, while at 1,545 meters it was 143. The party then retraced their steps with the result that at 1,650 meters the pulse fell to 124 and at 1,750 meters it was down to 114. Several factors naturally contributed to form the pulse curve, which was the same for all of the members of the party. The rarefaction of the air above a certain level began to cause an independent acceleration of respiration which modified the pulse curve of mere exertion, and this influence of altitude naturally persisted for some hours.

**Temporary Sterilization of Women.**—Blumberg reports six cases of this form of intervention, which he regards as much to be preferred to therapeutic abortion in women with tuberculosis, valvular lesions, psychoses, etc. It is not always desirable, however, to sterilize permanently; but hitherto we have had at our disposal not a single certain resource for the restitutio ad integrum. The author's method with this end in view consists in suturing one of the broad ligaments to the posterior surface

of the uterus in such manner that the ovary is separated from the fimbriated extremity of the tube by a continuous suture. The ovary lies loose in a pouch of peritoneum and whenever desired the "sterilization suture" may be removed. The author exhibited the first patient treated by him in this manner. She was at the time tuberculous, had borne several children and after her disease developed had undergone a therapeutic abortion. The sterilization was done by the vaginal route, and as one ovary was cystic it was extirpated. This was the only one in the series of six in which resection of the appendage was necessary, for in all the others both ovaries were sutured to the uterus. In all the patients menstruation went on as before, and thus far this appears to be the author's sole reason for the belief that the women can conceive after liberation of the ovary. Thus far he has not attempted the restitutio ad integrum.

**Scopolamine in Morphine Withdrawal.**—Mueller refers to Fromme's method of weaning from morphin under the influence of scopolamine. The same author had, however, made similar claims for dromine, codeine, brucine, and even for other substances the nature of which did not become public. One of these, termed by him "antimorphine," was alleged to be morphine itself disguised, and the public was warned against it by the Berlin police. The author evidently means to do a similar service to the medical profession, for he shows the danger of using such a powerful narcotic on enfeebled morphine victims. Some of these are besides incurable even in the presence of drugs which aid the majority, notably those with painful affections and habitués who have no desire to be free.

**Exposure of Inoperable Cancer of the Stomach to X-Rays.**—Finsterer sums up the experience in this field at Hochenegg's Clinic as follows: Resection of the carcinoma is to be carried out always when practicable. If local anesthesia is used the presence of severe complications should not deter the surgeon from intervention. After resection of cancer which is far advanced one should resort either to the usual deep radiation, or, better, expose the operative field to the direct action of the rays with the aim of destroying outlying cancer cells in the lymph nodes. This procedure should diminish the frequency of recurrences *in situ* and of liver metastases. In inoperable cancer the trial laparotomy which makes possible the diagnosis should be utilized for the exposure of the cancer area to the direct action of the rays, and synchronously a gastroenterostomy should be performed well toward the fundus—and if this is impracticable a simple jejemostomy. The mobilization of the stomach with its fixation immediately beneath the abdominal wall has been practiced in individual cases for a number of years by Czerny, Lexer, and others, but the author would elevate the intervention to the dignity of a routine procedure, in which he would incorporate a gastroenterostomy as essential part. Into the radiation field should be brought all continuous structures rich in lymphatics, notably the gastro colic ligament.

**General Asthenia of Connective Tissue and Wound Healing.**—Vogel cites a great number and variety of surgical cases intended to demonstrate that defective wound healing and defective scar formation depend upon a special connective tissue dyscrasia. Strict proof, however, cannot be forthcoming, until a number of surgeons investigate the subject from the author's viewpoint. The author has for years sought to determine the reasons for poor healing. Blood studies threw no light upon the subject, although the negative results may have been due to imperfect technique. The same holds good for the results of histological studies. It is possible that thorough studies might reveal some deficiency in elastic fibers. To the naked eye these subjects often show pallor, and cold cyanotic extremities.

**Galvanic Neuromuscular Excitability in Gravidæ.**—Seitz finds that in the latter months of gestation some 80 per cent. of gravidæ show a slight increase of galvanic excitability which reaches a maximum during delivery and declines in the puerperium. This phenomenon the author brings into relationship with a latent tetany, presumably a parathyretoxicosis, which is expressed at times by peculiar asthmatic attacks, often combined with malaise and tremor. Either asthma or tetany may occur alone in an otherwise normal gravida, as may also the mere galvanic excitability. Combinations and transition forms of various types are also seen.

**Tissue Necrosis and Arterial Arrosion from Infiltration Anesthesia with Old Solutions.**—Von Gaza reports two cases in his own practice (which appears to combine with surgery an occasional dental extraction). He keeps on hand a large quantity of novocaine solution, instead of preparing it extemporaneously, although he always boils it before injection. He had used the solution for long periods without any ill effects. In the first case of extraction of an upper molar he injected 3 cm. in the gum, anesthesia was perfect and extraction accomplished readily. It was seen that the cheek swelled more than usual and two weeks elapsed before it subsided. This was attributable not to the solution, but to the ulcerated state of the tooth, as swelling often occurs after such extraction, although not to this extent. The second case was one of multiple extraction in the upper jaw. Seven ccm. in all were injected, involving the entire gum of one side and the course of the anterior palatine nerves. After the extraction the side of the face swelled enormously, closing the eye. There was, however, neither discomfort nor temperature. A necrotic area formed in the hard palate and an arterial hemorrhage resulted. Several ligatures were applied and, although nearly three weeks had elapsed since the anesthetization, the parts were still insensitive. The author does not accuse the drug, but bacterial contamination of a sort not affected by heating the solution. In an experience of a hundred similar extractions he had seen nothing like it. He implies that the quantity injected may also have cooperated as a factor.

**Colitis Mucosa and Intermittent Fever.**—Couto of Rio Janeiro states that mucous colitis seldom exists alone, but is merely a local expression of a general catarrhal tendency involving all mucosæ which he terms polymyxoditis. There is a superior and inferior type. The condition rests upon a constitutional anomaly. In the case of colitis we see elevations of temperature which have a notable intermittent character at times, appearing as quotidian, tertian, quartan, or even with remissions of a week. As a rule rigors and sweats do not occur, and the rise does not exceed 38° C. The condition persists until the colitis is cured. A number of cases are given. One patient, a young married woman, suffered from meteorism, obstinate constipation, passage of much mucus, catarrhal endometritis—also the superior type was present—rhmopharyngitis, tendency to conjunctivitis, etc. The urine contained the ordinary evidences of intestinal putrefaction. The symptoms of colitis had been present for ten months. The fever, as is usually the case, had appeared in two major crises in which the intermittent type was pronounced. Also there were minor crises in the intervals, but these for the most part escaped the attention of the patient and were brought out only by the use of the thermometer.

## SUGGESTIONS TO MEDICAL EXAMINERS

BY THE INSURANCE EDITOR.

### ELEMENTARY PRINCIPLES OF LIFE INSURANCE.

*Annual Statement of Policy Values.*—The interests of the policy holders are fully protected by the laws which require every regular life insurance company to file an annual statement of its assets and liabilities, including the net legal value or reserve of all outstanding policies, as determined by the minimum valuations. This procedure enables the insurance department of each State to determine whether or not these companies are maintaining a reserve not less in amount than the net values of all policies in force, in accordance with the law. Such companies are, on this account, called "Legal Reserve Companies." They are also termed "Old Line Companies" to distinguish them from fraternal and assessment organizations whose premium rates are not fixed but are subject to increase as necessity may demand and which are not required by law to maintain an adequate reserve or to submit to any standard system of valuation to determine their solvency or the sufficiency of their rates.

A policy valuation in the annual statement consists in determining the present value of the claims which under the existing policies the company will have to meet and deducting from this the present value of the payments which under existing policies the company is going to receive; the difference between the two makes up the present value of the company's liability and must constantly be on hand as a reserve to meet the future claims as they become due.

The total present value of the claims which under the existing policies the company will have to meet may be determined by referring to the mortality and interest tables. The mortality table will tell how many will die in each year thereafter and how many will be living at the end of each year. From these data the amount of claims to be expected in each year until all existing policies have matured, either by death of the policy holders or by the expiration of the term for which the contract was written may be calculated. The present worth of these sums can then be computed at the assumed rate of interest, and the total amount will represent the present value of all the future claims.

The present value of the payments which under the existing policies the company is going to receive may be determined in a similar way, as the mortality table will tell how many policy holders will be living at the beginning of each subsequent year to pay the premiums called for by the policies in force. From these data the net premium income of each year until the last existing policy will have terminated may be calculated, and the present worth of all the future net premiums to be collected may then be ascertained by consulting the interest table.

For the purpose of illustration, it may be supposed that a company, after transacting business for a number of years, finds the present value of future claims amounts to $38,000,000 and that the present value of future net premiums comes to $34,000,000. There is then a deficit of $4,000,000, termed the legal reserve liability, and the company would be declared insolvent by the State authorities if no resources appeared in the annual statement to offset the deficit. If, on the other hand, the company has saved up the balance of its net premium and interest income from year to year so that the legal reserve has been maintained, after paying all death claims coming in during those years, there will be an accumulation of funds amounting to at least $4,000,000 to make good the deficit or legal reserve liability, and the company will then be declared to be technically solvent. In other words, the company has a fund on hand which represents the difference between the present worth of net premiums to be collected and the present worth of claims to be met under all outstanding policies.

The case cited as an illustration is simple but the actual carrying out of the valuation is an intricate and arduous matter owing to the great variety among the classes of policies, the ages at entry and the periods they have been in force.

The legal reserve must necessarily reach enormous proportions in the largest companies, each of which has between $100,000,000 to $200,000,000 of insurance in force and, in spite of the fact that this reserve is strictly demanded by the law, many legislators have allowed their minds to become uneasy over these large sums of money. They might have spared themselves this perturbation of spirit, when genuine and not affected, by acquiring some slight knowledge as to the full purpose of the funds in question. The reserve funds do not represent profits earned; on the contrary they are liabilities to policy holders under current contracts and consist of excess payments in the past, which are balanced by the defective payments to be made in the future as described in a previous article.

Life insurance companies already bear too heavy a burden of taxation. One single large company paid $1,333,534 in direct taxes in 1912, of which $233,187 represented the United States corporation tax, and most of the balance went to the various States. It is proper for life insurance companies to contribute their share toward the support of the government under the protection of whose laws they do business, but this is fully carried out by the usual taxation of the properties in which the insurance funds are invested. Direct taxes taken from the contributions made by policyholders, especially to mutual life insurance companies, can not be justified on economic principles, as they penalize thrift, foresight and prudence. Furthermore, a large part of the taxes levied directly on savings of any kind must necessarily be diverted to the benefit of the dissipated, indigent and spendthrift portion of the community.

---

**General Effects of Habitual Tobacco Smoking.**—Dr. F. Parkes Weber, in discussing the general effects of tobacco smoking on the human mechanism, says that, like relatively moderate indulgence in alcohol, it does harm in many cases. Weaklings cannot indulge in alcohol, tobacco, and many other things, which strong persons can for a time indulge in with apparent impunity. The weaklings are often protected by their very weakness, whereas the duration of life is often shortened in the strong by their very strength and their consequent *joie de vivre* and their tendency to indulge in excesses of all kinds. Thus indulgence in tobacco has a somewhat leveling tendency with regard to the duration of life. It probably tends to shorten the span of life of the strong, whereas persons of weak constitution are less affected because they are not often smokers. From this deduction, Life Insurance Companies cannot be considered losers owing to the smoking proclivities of the generality of men.

# Book Reviews.

Aufgaben der Glaukombehandlung unter der Kontrolle des Schiötzschen Tonometers. Von Prof. V. Hippel in Halle a. S. Price 1.20 M. Halle a. S.; Carl Marhold Verlagsbuchhandlung, 1912.

This monograph is one of 46 pages and consists of a careful analysis of cases of glaucoma of all forms that have come under the care of Prof. von Hippel. The cases are classified and considered under their separate headings. The condition of the cases when first observed, form of treatment and ultimate results are all given. Prof. von Hippel writes in the highest terms of the Schiötz tonometer as an instrument of precision and of value in the study of variations in intraocular tension. His very large experience, well-known ability as an observer, clinician and operator make the utterances of Prof. von Hippel on any subject in ophthalmology of exceptional value. A perusal of this very excellent monograph cannot but be profitable to all who are interested in the subject of glaucoma.

Textbook of Ophthalmology in the Form of Clinical Lectures. By Dr. Paul Roemer, Professor of Ophthalmology at Greifswald. Translated by Dr. Matthias Lanckton Foster, Member of the American Ophthalmological Society; Member of the American Academy of Ophthalmology and Oto-Laryngology. With one hundred and eighty-six illustrations in the text and thirteen colored plates. Volumes II. and III. Price $2.50 per volume. New York: Rebman Company, 1913.

The second volume of Foster's translation of Roemer's Textbook is one of 294 pages fully illustrated by figures in the text. There are two well executed colored plates. This volume is devoted to a discussion of diseases of the eyelids, injuries of the eye, diseases of the vitreous body, of the sclera, of the lacrymal organs and of the orbit; also glaucoma and "muscular or concomitant strabismus." The plan of the volume follows that of the first volume; namely, a series of lectures. There is no bibliography. Professor Roemer is a careful student, a close observer, and a man of convictions peculiar to himself. These are reflected in his work. The volume is particularly of value to the practicing ophthalmologist, but may be used to advantage by the student, especially in postgraduate study. It is one of the very valuable modern publications on ophthalmology.

The third and concluding volume of Roemer's work is devoted to a discussion of The Pupil, Paresis of Ocular Muscles; The Neurology of the Eye; Diseases of the Chorioid, Optic Nerve, and Retina and "Functional Testing of the Eye." There is an appendix in which the various forms of asthenopia are considered and an index covering the three volumes. The general excellence of the work is maintained in this volume. The text, which is in a semi-popular vein, is easily read and comprehended. The three volumes with a total of 896 pages form a textbook that is practical and that deserves to become popular with those seeking knowledge of ophthalmology.

Anesthetics and Their Administration. A Text-Book for Medical and Dental Practitioners and Students. By Sir Frederic W. Hewitt, M.V.O., M.A., M.D. Cantab., Anesthetist to His Majesty the King, Late Anesthetist to His Majesty King Edward VII, Physician-Anesthetist to St. Georgt's Hospital, Consulting Anesthetist and Emeritus Lecturer on Anesthetics at the London Hospital, Late Anesthetist at the London Hospital, Charing Cross Hospital, and the Royal Dental Hospital of London. Fourth Edition, Prepared with the Assistance of Henry Robinson, M.A., M.D., B.C.Cantab. Anesthetist to the Samaritan Hospital and to the Cancer Hospital. Seventy-one illustrations. Price $5.00 net. London: Macmillan & Co., Limited, 1912.

The publication of the present edition differs from its predecessors in several respects and has been rendered necessary by the extraordinary changes that have recently taken place in the practice of anesthesia—changes so revolutionary in their character that large sections of the book have had to be rewritten. Two wholly new chapters, one on local and regional anesthesia, and the other on the medicolegal aspects of surgical anesthesia in general, have been added. The latter chapter is written by Digby Cotes-Preedy, M.A., LL.M., Barrister-at-Law. He reviews briefly the main legal considerations that arise in relation to the administration of anesthetics, such as the present state of the law, the legal liability of the anesthetist, the public investigation of deaths under anesthetics, the steps that have been and are still being taken to remedy a state of affairs in this department of practice which, in the words of the recently appointed Home Office Committee, is a serious menace to the public. The medicolegal aspects of surgical anesthesia are considered under the following headings: (1) Present state of the law; (2) the legal liability of the anesthetist; single-handed operations under anesthetics; anesthetics in hospitals; (3) the public investigation of deaths under anesthetics; (4) the need for reforms and the steps that are being taken to secure them. The new chapter on local and regional anesthesia contains the following subjects: A. The properties of the principal drugs used for procuring local or regional anesthesia; B. The physiological actions of the drugs commonly used for producing local or regional anesthesia; C. Local anesthesia; D. The combination of local with spinal or general anesthetics; E. Spinal anesthesia: drugs used for inducing spinal anesthesia; the technique of lumbar anesthetization; the phenomena of spinal anesthesia; after effects; the mortality rate of spinal anesthesia. A description of many cases illustrative of the text are scattered throughout the book. The work contains practically everything of value on the subject and should be in the hands of all who administer anesthetics in private or hospital practice.

Medical Laboratory Methods and Tests. By Herbert French, M.A., M.D. (Oxon.), F.R.C.P. (Lond.), Assistant Physician, Guy's Hospital, etc. Third edition. Price $1.50. Chicago: Chicago Medical Book Company, 1912.

It is not surprising that a third edition of this little handbook has so soon become necessary. It confines itself to chemical and microscopical methods that are of established value in clinical medicine and presents them in such clear and condensed form as to render them most easily available. It is very complete and the values and fallacies of each method are carefully pointed out. The more complicated methods are entirely omitted. It is attractively bound and can be recommended without reservation as furnishing the average man all that it is necessary for him to know in order that he may perform the usual laboratory procedures. One error should be pointed out. On page 43 in the description of the test for indican in the urine, the statement is made that "Iodides, if present, will color the chloroform blue."

The Animal Kingdom Considered Anatomically, Physically and Philosophically. By Emanuel Swedenborg. Part on the Organs of Generation, and the Formation of the Fetus in the Womb, after which follow Chapters on the Breasts and the Periosteum. Translated from the Latin by Alfred Acton. With 10 anatomical plates. Price $3.00. Philadelphia: Boericke & Tafel, 1912.

This book should furnish an interesting glimpse into the mind of the famous Swede. It consists of well arranged quotations from anatomists describing the structure of the various parts of the generative system in man, followed by Swedenborgian "inductions" discussing the data of the anatomists and stating the hidden significance and adaptation of the parts to the purposes they serve. These teleological discussions are interspersed with numerous philosophical remarks on human life in general, and especially as it is evidenced in the function of procreation. The discussions of the eighteenth century thinker are frequently so strikingly original and true as to explain to a great extent the sway he once held over the minds of many men. The book should be a necessity to the faithful Swedenborgian, for the translation is a very readable one; it should likewise prove valuable to the medical reader interested in the development of human thought and knowledge.

Traité de l'examen des Crachats. Étude histochemique, cytologique, bactériologique et chimique, par Fernand Bezancon, professeur agrégé à la Faculté de Paris, méddecin de la Charité et S. I. De Jong, ancien chef de clinique médicale à la Faculte de Paris, ancien interne lauréat des hôpitaux. Price 10 fr. Paris: Masson et Cie., 1912.

In this work of 412 pages the authors argue for the utility and necessity of a careful chemical and microscopical examination of the sputa, since thereby is obtained much definite information regarding lesions of the respiratory tract. First is described the technique of examination together with a general study of the gross appearance and chemical composition of sputum; then follows a special study of the sputa in the different affections of the respiratory tract; and the work is concluded with a special and exhaustive study of the sputum of tuberculosis. The methods here described furnish a valuable addition to our diagnostic aids in respiratory diseases. The book is illustrated with eight well executed inset plates, of which seven are in colors.

## CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

*Held in Washington, May 6, 7, and 8, 1913.*

(Special Report to the MEDICAL RECORD.)

(*Continued from page 914.*)

*Wednesday, May 7, 1913.*

THE PRESIDENT, DR. WILLIAM C. GORGAS, IN THE CHAIR.

**The Life of Tissues Outside the Organism from the Embryological Standpoint.**—Dr. ROSS G. HARRISON of Yale University, New Haven, presented this paper and gave a lantern slide exhibition. He said that this subject had only come into prominence during the past few years. It was hoped that light would be thrown on the specific function of each tissue. The discoveries in regard to the survival of parts after the death of the organism from which they had been taken had excited wide interest. He did not know why this had occasioned so much more interest than the discovery that cells could be isolated, live, and grow outside of the organism from which they were taken. Comparatively very little was known about the activity of the cell and it was to make up this lack that the writer's studies had been carried out. The first to study the activity of cells were the experimental physiologists; then the method of isolation of parts was practised by embryologists. They cut the cell of the developing embryo and studied the isolated cell. This was the underlying idea of Bohn's work and these same methods he had used in the study of the development of the nervous system. The writer had separated the nerve cells from the rest of the organism. The method he had used in his observations was that of the "hanging drop culture." It was a combination of the ideas of other investigators rather than any particularly new device. In the study of nerve neuroblasts he found that the nerve fiber was not the outgrowth of the cell but was formed from the protoplasmic bridge which existed everywhere in the organism between the cells and could not be isolated. He thought he would try to see what the nerve cell did when there was no protoplasm. The parts of the central nervous system of the embryo were dissected out and then transplanted into a drop of lymph on the cover slide. Transplanted to lymph this tissue underwent changes in the course of a few days and spread out and flattened because of the liquefaction of the lymph and many cells wandered out from the tissue. He then watched what took place in the nerve cells. He also took portions of various other tissues of the embryo. He found that cells from the epidermis differentiated cilia; the pavement cells differentiated very queerly. After twelve hours it could be noted that the nerve fibers had grown out a long distance. These fibers came from isolated cells. He watched the character of the movements for six hours at intervals of eight minutes and found that the movements were very rapid, about one micron per minute. In order to show that they were real nerve fibers he had used the specific stain which showed neurofibrillæ. It was a specific nerve tissue without doubt. The protoplasmic activity had formed nerves. If they cut off these fibers there was a regeneration of the peripheral parts. Burrows had found a method by which one could use the blood of a chick as a medium and other discoveries were made so that the method could be used with any of the tissues of any of the vertebrates. Critics claimed that these activities were not normal because of the change conditions surrounding the cell, but they were not right, since there was regular growth and cell division. Not only was there differentiation but actual cell multiplication and increase in volume of the tissues, but the longevity was not yet worked out. They knew, however, that these tissues could be kept alive for a long time. In order to produce a perfect reproduction of the tissue it should be demonstrated that the tissue could be kept alive as long *in vitro* as it would have lived in the organism from which it was taken. If the tissue had been taken from an animal that lived on an average four years, then they should be able to keep the tissue alive for that length of time. These methods were of distinct use in studying the phenomenon of the living organism. There were many possibilities for study in this field by changing the environment under which the experiments were conducted. This method, while producing cell division and multiplication, had failed to show any form development; the growth remained simply a mass of cells. In discussing the effect of the medium on growth and differentiation the writer said that the tissues differentiated in salt solution, but they had need of solid support or there was no movement of the cells and no growth. If nerve fibers were on a solid support when they left the cells this might be a visible chemical process. This brought him back to the nerve problem, and it seemed evident that the protoplasmic bridges between the fibers formed the support. The results that they had obtained showed that this method was applicable to the study of embryonic cell movement and differentiation.

**The Life of Tissues Outside the Organism from the Physiological Standpoint.**—Dr. MONTROSE T. BURROWS of New York presented this paper. He said that there was no line between the morphological and the physiological aspects of this subject, and he hoped that he would be pardoned if he repeated what had already been given. The object in growing tissues outside of the body was that they might be observed in the living condition, and this could not be done by Loeb's methods. In 1910 he had begun the study of cultures with the idea of developing a method which would be applicable for practical experimental purposes. Lymph had hitherto been used as a culture medium and this could only be obtained in small quantities and its consistency was not always constant. He therefore turned to blood plasma as a promising medium and prepared fibrin from the blood of chickens. His observations on the growth of chick embryos were similar to those of Dr. Harrison and confirmed the results that Dr. Harrison had pointed out. He thought it would be a good idea to test the applicability of these methods to adult tissues. His observations included experiments on the tissues of dogs, cats, rats, guinea-pigs, and man. Tissues from all of these sources grew luxuriantly except those from man. The human plasma went into solution at once. There were some small growths in the case of human tissue, but only a few. The undue liquefaction of the medium led to the early death of the tissue. Practically all other tissues caused liquefaction in varying degrees, but it took place slowly. He had experimented with the chick embryos in many liquids. They grew rapidly in isotonic sodium chloride solution of various strengths and the growth was prolonged and increased by the addition of chloride of potassium. The growth was the same as that in a wound. The connective cells grew as isolated cells in the surrounding medium. The growth in each variety of cell was characteristic of its kind. The nerve cells appeared as axis cylinder cells, the blood cells as amebic cells. The growth depended upon the medium and was often greater in weak solutions than in strong ones. Adult striated muscle succumbed, but embryonic muscle wandered, divided, and differentiated. The growths would keep in an inactive state as long as six months. To effect this preservation the tissue was placed in a drop of plasma and the whole tightly sealed. If there was sufficient medium the tissue would retain its life for a long time. This field offered a prospect of reproducing every form of cellular activity seen in the body. Wound healing had been imitated by culture through the movement of epithelial cells. If two portions of tissue were placed near one another in the medium each would send out cells toward the other and the tendency would be for the cells to fill the intervening space. Dr. Harrison had called attention to the need of solid body support to the growing cells. Contact with the cells unless violent did not stimulate movement. A single cell in a culture medium tended to move away and liquefy from a large mass rather than from a small one. All movement was due to a chemical process. Given the diameter of a wound, by the application of the principles of cell proliferation the form of healing could be predicted. It had been suggested that by an application of their theory wounds might be made to heal in a few hours. Practically, it did not happen in so short a time. The fibrin lying between the edges of the wound was too thick and contracted in proportion to the amount of fibrin present. Cell development began only when the cells ceased to wander and located in a clot. It was better to have a colony of cells in the culture medium as this produced sufficient liquefaction to provide nutrition. There were amebic movements at the poles of the cells accompanying cleavage at the equator; these movements were due to external influences, but division was due to internal forces. The writer had also experimented with heart muscle cell. The question as to what caused the heart to beat had long been discussed and two theories had been advanced, the myogenic or automatic, and the neurogenic. The heart cells were freed from all nerve cells and it was found that they continued to beat rhythmically. This seemed to him to be conclusive evidence of the truth of the myogenic theory.

**The Life of Tissues Outside the Organism from the Pathological Standpoint.**—Dr. Robert A. Lambert of New York read this paper, which was illustrated by lantern slides. He said that those who were directing their energies to problems relating to the nature and cause of disease were interested in the new methods of growing cells apart from the organism mainly on account of its possible application to the study of the various morbid processes affecting the human body. In his opinion the new method offered several very definite advantages in that it allowed one to observe directly under the microscope changes taking place in living functioning isolated cells, thus making it possible to pursue with ease many questions in the field of pathological histology, the solution of which has seemed to wait on the discovery of a technique of this kind. In the second place, it permitted one to eliminate many factors which in experiments on the animal body were a source of much confusion, as for instance, nervous control. In the third place, the isolation of some single factor for the purpose of special study was made possible. In the fourth place, one was able to introduce more easily into an experiment known and measurable factors such as changes in the physical and chemical composition of the medium, introduction of specific toxins and poisons, variations in temperature, etc. It was obvious that not all problems having to do with the activities of cells was open to attack by these methods since every tissue could not be made to grow *in vitro*, or at least not up to this time. The number of tissues that could be successfully cultivated was not inconsiderable, including connective tissue cells, bone, cartilage, endothelium, skin and corneal epithelium, intestinal epithelium, malignant tumors and possibly also thyroid and kidney epithelium. Certain cells, such as ganglia cells, seemed to survive though they did not proliferate. The problems which presented the most fruitful field of application might be classified under three headings: First, morphological questions; secondly, questions in immunity, including cancer immunity, cellular and bacterial immunity, and thirdly, problems relating to the cultivation and study of the viruses of certain infectious diseases, especially those in which the specific intracellular bodies had been described. He showed pictures contrasting the discrete wandering of the sarcoma cell with the sheet-like or grouped type of growth seen in the next picture, which was one of mouse carcinoma. He emphasized this type of growth, not only because it represented a general difference in the growth of epithelial and connective tissue, but also because it showed that the growth of cells *in vitro* and *in vivo* was not essentially different. The next picture showing individual sarcoma cells illustrated the phenomenon of ameboid movement. It was suggested in this connection that in the spread of the tumor through the body the activity of the individual cell must play an important part. In a sarcoma culture they had seen a cell travel a distance of five millimeters in 48 hours, a rate that would easily enable a cell in the center of the breast to reach the axila in six or eight weeks. That fat in the cells was a result of degeneration of the cell cytoplasm, or that cells died through a fatty degeneration was disproved by the fact that cells containing fat moved about freely and underwent perfectly normal miototic division, that the fat might completely disappear when the cells were transferred to fresh culture medium, and that by diluting the plasma with Ringer's solution the amount of fat accumulated was directly proportional to the amount in the plasma medium. They had concluded that the presence of fat in the cells was referable to some unexplained disturbance in metabolism. The whole question of normal and pathological fat accumulation seemed to have been opened by this technique. Another problem which had interested them was the development of foreign body giant cells. By adding lycopodium spores to cultures of chicken spleen they had been able to produce *in vitro* giant cells of the familiar body type. They had been able to determine that they were formed by a fusion of cells and to decide in a general way as to the nature of the cells that went to form them. They demonstrated that connective tissue cells did not take part. A comparison of the growth of normal cells and cancer cells *in vitro* showed that the normal connective tissue cells divided in an orderly regular manner; only normal mitoses were observed and the time required for division was quite constant; whereas in sarcoma cells atypical division figures of all kinds were seen and the time required for division varied within very wide limits. This method made it possible to observe the phenomena of cell division in the living mammalian cell. Normal tissue cells seemed to be much more hardy than sarcoma cells, showing often a markedly accelerated growth after the first or second transfer, while sarcoma cells showed a diminished activity. They also found that connective tissue cells were definitely more resistant to high temperatures than sarcoma cells. The writer then related his experiments with cancer immunity and cellular or cytotoxic immunity. He concluded from these experiments that cytotoxins were easily demonstrable in tissue cultures and that cancer immunity was not a type of cytotoxic immunity. In the experiments upon the question of cytotoxin specificity two series of guinea-pigs were immunized respectively with rat sarcoma and rat embryo skin. Plasma from each series of animals was used for cultures containing both kinds of tissue. These experiments showed that sarcoma might immunize completely against skin and *vice versa*. There was no evidence of even a relative specificity. Red blood cells would immunize against other tissues. There was another field of pathological investigation in which this new method might be applied, that was in the study of viruses and specific lesions of infectious diseases in which the living agent had not yet been identified, as rabies, vaccinia, variola, measles. Efforts had been made by the writer of the paper in association with Dr. Steinhardt and Dr. Poor at studying rabies and vaccinia. They had tried to see if Negri bodies would show any development or multiplication *in vitro* when fragments of brain from rabid animals were incubated in blood plasma. No development or multiplication of Negri bodies in rabid brain cells took place *in vitro*, so far as they could determine. They found, however, that in the control preparations in which normal brain alone was incubated, the same structures also appeared. In the latter case the bodies certainly represented some degenerative changes in the brain cells. They, therefore, regarded their results as favoring the idea that the Negri body was not a parasite but a specific cell degeneration.

Dr. Leo Loeb of St. Louis said that these papers had demonstrated clearly the features of the different tissues when taken out of their natural surroundings and put into a new environment. They had done this in very much the same way as had previously been done with bacteria. The methods that he had used were based on the same principles as those just related, but he had used larger pieces of tissue and had put them into a tube. This had the advantage over the cover method that enabled them to study the gases and yeast and to eliminate the leucocytes. He had found that it was possible for transplanted tissue to grow without an outgrowth of cells so long as it was in contact with a solid or semi-solid substance. If two pieces of tissue were placed near each other the cells grew from each piece toward the other. Different tissues acted differently in the plasma, for instance, the tissues of the guinea-pig absorbed the plasma and they would be found to be growing when one had supposed them dead. Epithelium did not grow as well as connective tissue. His experiments with long series of transplantations had led him to believe in the potential immortality of ordinary cells.

Dr. Warren H. Lewis of Baltimore said they had been growing tissues in known media, such as sodium chloride, calcium chloride, and sodium bicarbonate. They found that in varying percentages of sodium chloride tissues migrated and mitosis took place in such simple solutions as 0.5 to 1.5 per cent. solutions of sodium chloride without difficulty. A high percentage solution caused delay of the cell activities. The saline solution offered an advantage over the plasma in that it did not cling to the cover glass and one could study the living nerve on glass. It could be seen that the processes anastomosed freely with other fibers so that a true network was formed and stains showed that the neurofibrillæ passed from one nerve fiber to another. Mitosis was very frequent with various solutions. He had studied the subject of fat in the cells and the relation of the fat in the cells to that in the media, and had found that the first cultures never contained fat, but he had been able to produce cultures in which the accumulation of fat was so enormous that the cell structure was practically obliterated. Rejuvenation by transplantation could be reduplicated in artificial media to which cane sugar or dextrose had been added and the occasional addition of a fresh drop of the medium doubled the time of life and growth. The growth was striking after the addition of alcohol or ether, but not if there was more than two or three per cent.

---

**Congenital Atresia of the Bile Duct.**—Ferruccio Vanzetti made a careful anatomical and histological study of a case of this condition which he discovered in the dissecting room. The case was that of a baby four months old which had been born markedly jaundiced, and had remained so until death. The study of this case showed that congenital atresia of the biliary passages is followed by cirrhotic changes in the liver.—*Archivio per le Scienze Mediche.*

(Special Report to the MEDICAL RECORD.)

SECTION OF PEDIATRICS.

*Wednesday, April 30.*

(*Concluded from page 919.*)

**Nerves and the Nursing Mother.**—Dr. CONWAY A. FROST of Utica read this paper. He said that the influence of the nervous system on the milk of nursing mothers had more far-reaching effects than was at first realized. Were the same time and energy expended in finding out the cause of the mother's derangement that was spent upon the adaptation of cow's milk, something of importance might be forthcoming. The average physician if called to an infant with digestive trouble, and if he could not immediately straighten it out, instead of trying to rectify the trouble with the mother's milk turned to his favorite textbook and read upon milk formulæ, and the long struggle began. When something went wrong with the mother's milk, the average physician never looked further than to inquire whether there had been a dietetic error. He believed that they were on the wrong track. The farmer's boy was very careful in driving the cow home, not to irritate her for fear of spoiling the milk, but little care was taken of the nursing mother in this respect. He believed that a life devoid of nervous shocks was of far more importance for the well-being of the nursing mother than a diet devoid of minor indiscretions. Just how these nerve shocks interfere with the proper secretion of the proper food he did not know. Metabolism they knew was often inhibited, the whole digestive process upset, and the sweat glands inhibited or stimulated by emotion, and yet they utterly ignored the emotional effect on the sensitive milk glands of the breast. It had been his experience that the proteids had been increased during such nerve upsets, not that this was the only change, but it was the most palpable one; it had been his custom to increase the number of bottle feedings temporarily (if the child had been fed on mixed feedings), and also to try to get a higher fat and lower proteid in the mother's milk. The difficulty at times might originate in an increase in fats. If these changes occurred, why not others? They should strive to get some light on this subject, and that was his object in writing this paper.

Dr. FLORENCE STAUNTON of Utica said that some facts were difficult to account for; some nervous mothers were good nurses, while some phlegmatic women could not nurse their children. The care of the pregnant woman should be begun early and the woman prepared to nurse her babe. Pregnancy and nursing were subjects upon which women did not think enough. The pregnant woman should have a more thorough examination than was always customary. It was not sufficient to examine the urine; nervous troubles and eyestrain should receive attention. If a fixed fee could be charged for care from the beginning of pregnancy until after delivery, the physician would get the cases early. Another point that should be emphasized was that more patients should be exercised in starting the milk supply. Frequently inability to nurse a child was the result of nervous fear on the part of the mother lest she would be unable to perform that function. A great deal could be done in such cases by restoring the confidence of the mother. Sometimes it required five or six weeks' work to establish the milk supply. Mothers should not nurse their babies longer than the tenth or twelfth month, as long nursing unfitted them for a succeeding pregnancy or lactation.

Dr. CORNELIA W. THOMAS of Rochester said the problem of nerves in the nursing mother was not different from that of nerves in any other mother. The baby was influenced by the nerves of the mother before the child was born as well as after. The cause might be anemia, any of the various pelvic affections, or a nephroptosis. For all of these conditions the physician could do something, but she did not know what could be done for the careworn and overworked woman who had a family dependent upon her.

Dr. T. WOOD CLARKE of Utica said he was glad they had gone back to the woman, for however much they might disagree on the subject of artificial feeding they all agreed on the breast for the baby for one year. The number of mothers who could not nurse their children was insignificant if one attacked the problem in the right way. The mother should be made to believe that she could nurse her baby and she would be able to do so. Dr. Clarke cited cases which he believed confirmed this statement.

Dr. IRA S. WILE of New York called attention to the mistake that was often made of thinking a mother could not nurse her child because she had no milk on the second or third day. Instances had come to his notice where the flow of milk had been established three months after delivery. The best stimulus was the suction of the baby. When the mother went to the milk station under the impression that she could not nurse her babe, those in charge of the station should see that an effort was made toward maternal nursing before resorting to artificial feeding.

Dr. ELIZA M. MOSHER of Brooklyn called attention to the frequency of inverted nipples. When this defect was present the mother suffered a great deal of pain at first and it took considerable time to get over the fear of further pain. It was remarkable how common this condition was. For many years Dr. Mosher said she had made it a practice in the routine examination of girls and young women to note without calling their attention to the fact whether or not the nipples were inverted, and when she met with this defect she advised the mother of the girl to see that corrective measures were taken, as much trouble could thus be spared the future mother. Dr. Mosher thought that the pressure of the corset bone was responsible for inverted or defective nipples and that the matter should be brought to the notice of the corset manufacturers. In the course of routine examinations pediatricians frequently had opportunity to observe the condition of the nipples and should advise early treatment. Enlarged breast glands might result from infection absorbed from accumulations lodged in the nipple depression.

Dr. A. CONWAY FROST of Utica said that the object of his paper had been to emphasize the desirability of keeping away from the cow and to inquire into the effect of nervous disturbances in the mother, not to discuss the treatment of nervous diseases in women.

**The Value of Discipline in the Care of the Sick Child.**—Dr. T. WOOD CLARKE of Utica read this paper. After pointing out that upon the control of naughtiness depended the success or failure of one's efforts toward a diagnosis and cure in the sick child, and calling attention to the fact that too frequently when there was a prospect of a long illness the endeavor was made to make the little one as happy as possible by endeavoring to gratify every wish which was a very wrong course, he described a method he had used in suppressing howling which consisted in placing the palm of the hand over the child's mouth and nose every time he began to scream. The writer concluded that the lack of discipline might be responsible for actual illness and that whatever method of disciplining was adopted, and to whatever extent circumstances made it possible in the individual families to carry out any measures, one should always remember three facts: A healthy child needed discipline, an ill child needed it more, and a nervous, spoiled one needed it most of all. By being strict with a child one increased his chances of recovery from an acute illness, made the household more habitable, the child far happier, and, most important of all, one destroyed the cocoons which if allowed to develop would, in later years, hatch out into the devastating blights of neurasthenia, hysteria, and even insanity.

Dr. GEORGE DOW SCOTT said that the psychology of the physician was the same as that of the parent and he did not believe in suppressing a child's cry. He thought one should always deal frankly and honestly with the child. When he met a refractory child and had to hold him down he made a joke of the affair and soon the child came to regard it in the same light.

Mr. HERBERT WEET, principal of the Rochester schools, said there were some points brought out in the paper that were quite as vital to the teacher as to the physician. The paper had essentially been a plea for self-control in the growing child, and the point had been made that this was for the welfare of the child. If that was true of the physical, it was even more true of the mental and the moral. Education was essentially the training of the child in self-control and similar qualities. The fact that these elements in education seemed to hold a subordinate place to mere book knowledge was due to the fact that the community demanded that the children be able to pass examinations. The child acted and developed through instincts of play, curiosity, imitation, and repetition. There could be no growth or development except as there was opportunity for the expression of these instincts. The great problem of education had been that of discriminating intelligently between the instinctive tendencies which should be developed and those which should be suppressed. This was the problem upon which the Montessiore and Froebel methods were based. Elementary education should bring out and develop self-control, honesty, frankness, and simplicity, and real instruction was one of the means to this end.

Dr. T. WOOD CLARKE said that he thoroughly agreed with

all that Dr. Scott had said; he was not brutal. The cases cited in which he had suppressed the crying were exceptional cases. He certainly agreed with him as to the necessity of implicit honesty in dealing with children. His method of suppressing the cry did not hurt the child in any way.

*Thursday, May 1.*

**Care of the Newborn.**—Dr. C. G. Leo-Wolf of Niagara Falls, N. Y., read this paper. He said that he would not attempt to bring out anything new, but he wished to emphasize the following points: 1. The feeding of the newborn should be in the hands of the pediatrist from the first. The infant should not be fed at all on the first day, only once or twice on the second, and five times a day at intervals of four hours from the fifth day on. 2. The antiseptic care of the infant required that in hospitals and among the wealthy two nurses should be employed, one for the mother and one for the infant; if there was only one nurse, special care should be exercised to prevent infecting the infant with bacteria from the lochia. 3. Wiping out of the mouth of the infant was no longer practised. 4. Books on the care of the infant intended for mothers and nurses should not contain any formulæ. 5. Registrars of vital statistics should be prevented from furnishing the manufacturers of patent and proprietary foods with the addresses of young mothers.

Dr. John Ragone of Buffalo said that he was in hearty sympathy with the reader of the paper in believing that the newborn baby should be under the care of the pediatrician in the hospitals, and also in private practice where possible. The obstetrician was not interested in the baby, as a rule, and the general practitioner was not careful enough of details. The result was that eventually the pediatrician was called in, but he should be called in before the mischief was done that was often so difficult to repair. He had been following the four-hour method advocated by Dr. Leo-Wolf and had found it satisfactory. The necessity for cooperation between the obstetrician, the pediatrician, and the general practitioner should be emphasized. Abscesses of the breast should be regarded in the same light as stitch abscesses or infected wounds were now regarded in surgery. They should never occur. Surgical cleanliness should be insisted on in the care of the baby. Another reason for placing the baby in the hands of the pediatric nurse was that few nurses outside the large hospitals in the cities had proper training in the care of newborn infants.

Dr. De Witt H. Sherman of Buffalo said that in order to avoid the gripes mentioned by Dr. Leo-Wolf he advised the early administration of a weak solution of bicarbonate of soda. Bicarbonate of soda was one of the best mucus solvents and hence cleansed the mouth and stomach and allowed easier gastric secretion; as an alkaline diuretic it relieved renal colic due to the early passage of uric acid crystals and their salts, and it prevented the abuse of the child by locating the colic in the proper place rather than considering it as an intestinal one and resting satisfied with castor oil treatment. The baby should be put to the breast every six or eight hours during the first twenty-four hours and a little more frequently after that time until the milk came. Then the interval should be regulated in direct proportion to the amount taken and the comfort of the child. The scales were absolutely essential as a guide in determining this interval. A regular four-hour interval should not be attempted in every case. He advised an accessory feeding once a day both that the mother might have some liberty and that the child's digestive ability might be tested and preparation made in case of accident to the maternal milk supply. Dr. Sherman laid great stress on the aseptic handling of the newborn babe. A sterile cloth should be laid inside the blanket in which he was wrapped. In removing the vermix caseosa the oil or vaselin should be sterile. The water in which the baby was bathed should be as sterile as that coming from the heater and cooled. If the baby's mouth was cleansed, the nurse's hands should be previously sterilized and sterile gauze used for the washing. The rectal temperature should be taken as frequently for the babe as for the mother, as temperature was an important indicator of the child's condition.

Dr. Thomas S. Southworth of New York asked Dr. Leo-Wolf what disposition he made of the old idea that nursing was of assistance in the process of involution of the uterus. He said that he could not quite accept the idea of the long interval before the first feeding. One might take a middle ground by putting the child at the breast four times during the first twenty-four hours. Colostrum was a natural laxative and there must be a reason for this. To his mind the four-hour interval had not been proven a necessity for all infants. On the Continent the mothers appearing at the clinics had a much larger quantity of milk than those in this country usually had, and their children probably got all the milk they needed. Here it was a different matter where the question of a sufficient amount of milk hung in the balance. Dr. Clarke had told of a woman on the Continent who nursed eight infants. This remarkable milk supply was the result of stimulation. Where stimulation was needed the four-hour interval was a mistake. Where the milk supply was deficient much could be done to improve it and a popular opinion ought to be created that a baby should not be weaned without a consultation with the pediatrician.

Dr. T. Wood Clarke of Utica asked Dr. Leo-Wolf if it was his practice to have the babe nurse from one or both breasts at a feeding. If the breasts were nursed alternately there would not be enough stimulation for the mother inclined to have a limited supply of milk. If the child did not nurse during the first two days, it would have to have castor oil and he was strongly opposed to this. When the milk seemed to be insufficient the infant should be put to the breast every two hours and instead of giving one or two accessory feedings a little supplementary feeding might be added after the child had obtained all that it could from the breast. Dr. Clarke asked what progress the Society for the Prevention of Infant Mortality was making with its book for mothers.

Dr. Sherman replied that he understood that they were working on the book and that it would be a model one. The title of the book was "Saving the Baby."

Dr. Carl G. Leo-Wolf of Niagara Falls, in closing the discussion, said that he had not mentioned castor oil because he did not use it. He thought the suggestion of giving bicarbonate of soda very valuable. He was not a faddist on the four-hour interval but he had found that it worked well with most normal babies. He would not use the plan with a premature baby. So far as his experience went he had never seen a post-partum hemorrhage result from not putting the child to the breast. On the other hand, where there were afterpains he had found that they were increased when the child was placed at the breast.

**Enuresis and Chronic Digestive Disturbances.**—Dr. Frank Vander Bogert of Schenectady said that it was no doubt true that involuntary passage of urine was due either to increased irritability of the bladder or to a diminished tone of the sphincter, influenced by increased excitability of the lumbar center or interference with normal brain control. It was to the underlying cause of this excitability that he wished to direct their attention. Reflex irritation was of importance in the production of enuresis since not infrequently cures followed the removal of these sources of irritation. The same local conditions, however, occurred with even more frequency in children who were not bed-wetters and the frequent failures following treatment directed toward these lesions made one exceedingly skeptical as to their very great etiological importance. According to the opinion of Leonard Williams, adenoids and enuresis were associated only because they were due to an underlying cause which he considered to be thyroid insufficiency. The writer said that in his personal experience thyroid had failed more frequently than it had succeeded and a search of the literature had failed to reveal any startling results from its use. If hypertrophied tonsils were considered as a part of a general catarrh of the intestinal tract, the relief afforded by their removal might fairly be considered to be due to the effect upon the gastrointestinal catarrh and the subsequent improvement in the general health. The instances in which changes in the urine were responsible for the production of enuresis were so rare that this factor might be excluded in considering the etiology of the condition. So many functional and nervous disorders of childhood had been found to be dependent upon chronic digestive disturbances that the question had arisen in the author's mind as to whether urinary incontinence might not be traced to the same source as an underlying cause. With this object in view he had studied the histories and symptomatology of fifty children, who were the subjects of incontinence. The dietetic histories invariably gave ample reason for suspecting the alimentary tract. Practically without exception gross errors in feeding were noted, and often dated from early infancy. Prolonged nursing certainly predisposed to poor development and consequently to digestive disturbances in later childhood; and the more frequent dietetic errors seemed to be in the direction of sweets and starches. A few were possibly excessive milk drinkers. Possibly it would be more fair to include only those cases in which a large amount of indican was present in the urine and justified the diagnosis of a toxemia of this nature. Meat excesses were not so frequent. Irregular feeding and feeding between meals apparently played a most important part. Practically all the patients showed symptoms common to gastroenteric

disturbances. In discussing the association of enuresis and rheumatism in children, Still said that he had observed that rheumatism occurred sufficiently frequently in children with enuresis to make him watchful for it. He also said that the rheumatic child was apt to be a nervous child. It seemed just to assume that both the rheumatism and the nervousness were manifestations of an intestinal toxemia. Other arguments in favor of the intestinal tract as the seat of the underlying cause of enuresis were the frequent occurrence of enuresis after acute catarrhal diseases and the relapses noted during acute digestive derangements. Writers of textbooks had given comparatively little attention to the part played by the digestive tract in causing enuresis and of the possibilities of treatment directed toward the improvement of the digestive process. The dietetic treatment advised had apparently been with the object of changing the composition of the urine rather than of increasing general muscular and nerve tone, and of preventing toxemia. The improvement of enuresis during warm weather argued in favor of the catarrhal condition as a causative factor. Reflex irritation arising from the fecal masses of chronic constipation or parasites might be factors in the production of incontinence as they were also factors in the causation of intestinal catarrh. If they accepted this theory as to the causation of enuresis, treatment must be directed to the gastrointestinal condition. The dietetic treatment consisted in a definite number of meals given at regular intervals sufficiently long to insure complete digestion and the establishment of an appetite, absolute abstinence from food during the intervals, a mixed diet containing vegetables to stimulate peristalsis, and to secure regularity of the bowels. The diet should be based on the history of the particular excess and upon a study of bowel movements in order to determine what particular food stuffs were at fault. Mastication should be thorough and good hygiene should be maintained. Medical treatment was practically limited to the use of laxatives temporarily and to intestinal antiseptics.

Dr. De Witt H. Sherman of Buffalo said that the principles elucidated by Dr. Vander Bogert in his paper had struck him as striking at the root of nocturnal enuresis. A child with a comparatively stable nervous system might have adenoids, or an adherent prepuce, or intestinal parasites, and yet have good control of the sphincters, but in a child with unstable nervous system these irritations produced trouble. Hence the treatment should be directed to building up the general nervous and physical tone and the removal of the various reflex influences. In spite of these measures some children still continued their bad habits. With many of these he at first timidly resorted to psychotherapy and with startling results. The physician was the one who could make the greatest impression on the child, though if the parents had sufficient force of character they might make the so-called night suggestion. This treatment seemed particularly adapted to the nervous high-strung child, especially if he was a good patient. Dr. Sherman cited a number of cases which were very convincing as to the effectiveness of psychotherapy in his hands. He agreed that adenoids belonged to the group of catarrhs of the gastrointestinal tract and could not see upon what principles one could expect the administration of thyroid extract to be followed by any startling results.

Dr. R. D. Moffett of New York called attention to the fact that some of the foreign physicians believed that enuresis in many instances was due to mental defectiveness. Many of these children were neuropathic and responded easily to suggestion. In those that had chronic intestinal indigestion one had to use means other than suggestion. Abroad they applied the faradic current over the sacrum and bladder and a number of cases were found to respond to this treatment.

Dr. Charles Herrman of New York said that a large percentage of these cases represented purely functional neuroses. There had been about twenty different methods used in the treatment of these cases and they had given very variable results. If there was any great bodly change suggestion would not work. In regard to the association of adenoids and enuresis, Dr. Herrman said he wished to remind them that about 25 per cent. of all children had enlarged adenoids and consequently this association was not surprising and did not necessarily mean anything. He had tried thyroid extract but had not secured any very brilliant results with it. He had had a large number of cretins under his care and many of them had enuresis, and he could not see that thyroid had any effect upon the incontinence. If chronic intestinal intoxication had anything to do with enuresis it was important to know it as something that would help to build up the general condition and assist in overcoming the enuresis. Perhaps one reason why the enuresis improved during the summer was because most of these children being of nervous temperament were influenced to a considerable degree by the long school hours and that being out of doors and relieved of pressure of school work made the difference.

Dr. Frank Vander Bogert of Schenectady said that Dr. Vander Veer of Albany had found in a large series of cases of adenoids that 10 per cent. had enuresis.

**A Plea for the More Frequent Use of Lumbar Puncture.**—Dr. Edward J. Wynkoop of Syracuse presented this communication. He said that the points which he wished to emphasize particularly were the following: 1. Lumbar puncture was of great value from a diagnostic and therapeutic standpoint in other than true meningitis cases. 2. It had not yet received the endorsement it should have and it was not as often used as it should be by the general practitioner. 3. It was the only prompt and sure way to secure a positive diagnosis in cases showing suspicious meningeal symptoms whether alone or accompanying some other disease. 4. Therapeutically by relieving the brain pressure, it was much more prompt and effective than drugs. 5. Many cases showing suspicious meningeal symptoms cleared up almost at once after a lumbar puncture. 6. In the treatment of convulsions from any cause, it was a remedy of great value. 7. Its technique was simple and it should be promptly and easily done by the general practitioner.

Dr. Walter Lester Carr of New York sent the following discussion which was read by the secretary, in which he stated that lumbar puncture was now so firmly established that it was used in hospital work more often than paracentesis of the chest and abdomen. The conditions for which the puncture was performed were: 1. When there were evidences of pressure symptoms occasioned by changes in the brain or spinal cord. 2. When it was deemed advisable to study the fluid in the spinal cord so as to detect pathological changes. 3. When any substance was to be injected for therapeutic purposes. Lumbar puncture should be done more often in children suffering from the effects of cerebral concussion and other brain injuries. The uses of lumbar puncture should be extended to private practice for with ordinary surgical cleanliness there was no danger to the patient. Local or general anesthesia was not required in infancy but in childhood a local anesthetic might be applied, or ethyl chloride inhaled. A study of the physical, chemical, cytological, and bacteriological characters of the spinal fluid might be of supreme value and the symptoms now designated as meningism might be classified.

Dr. Joseph Roby of Rochester said that with regard to lumbar puncture he wished to ask if any of them had ever seen a case of anaphylaxis. He related an instance in which he had administered tetanus antitoxin to a man and immediately upon giving the injection the man succumbed. In another case of a child with cerebrospinal meningitis, who had previously been healthy, he did a lumbar puncture and finding the fluid cloudy injected serum. The child gave a few gasps and died. The death might have been due to a change in the pressure of the spinal fluid, or it might have been due to anaphylaxis; he did not know which. Dr. Roby said he had still another case which he wished to report. He was called to see a child that had been in convulsions from 2 o'clock in the morning until 8. The child was 8 years of age and the convulsions were more like hysteria. The temperature was 101° F. and the pulse 110. There was no Kernig's sign; the reflexes were not exaggerated, and the neck was not stiff. He thought at first that he would not do a lumbar puncture, but a few hours later he was called again and found the child with a temperature of 103°. He tapped the child and the fluid came clear. It contained no organisms though he did not look for tubercle bacilli. The urine was normal. After the puncture the temperature dropped. There had been an increase in the white cell count. Dr. Roby asked whether hysteria could produce spinal pressure and an increase in the white cell count.

Dr. T. Wood Clarke of Utica said that he had had a baby die just as Dr. Roby had described, only the death occurred just before he introduced the serum.

Dr. Edward J. Wynkoop of Syracuse said that the fluid should be drawn off rather slowly and that two or three tappings were sometimes preferable to only one. In his experience he had never had any such accidents as had been reported. When there was an infection, such as pneumococcus, accompanied by meningeal symptoms, if one did a lumbar puncture, the danger of meningeal complications would be obviated.

**Studies from the Infants' Summer Hospital.**—Dr. Joseph Roby of Rochester said that he had no paper to read but wished to exhibit a few devices that he had originated. The first of these was a method of capping nurs-

ing bottles that was intended for large institutions and milk stations. It had some advantages over the cotton stopper and was more economical than the metal stopper. The intravenous method of making injections was being used more and more and simple apparatus was a necessity. He had constructed a comparatively cheap outfit which was intended for localities where one did not have the conveniences of a laboratory. It had been designed mainly for the injection of salvarsan but was equally suitable for other intravenous injections. It could be used over any kind of a fire that happened to be convenient. The outfit was portable and could be taken anywhere and be ready for instant use. In the *Journal of the American Medical Association* for April 19 there was an article on the advantages of having a universal chart for clinical purposes. He had looked over the charts of many hospitals in the endeavor to find one suited to his purposes and had been surprised at the variety of charts in use. If all could use the same chart it would be a saving of considerable expense in addition to the other advantages. He had devised a chart which he presented and which was similar to that used at Bellevue Hospital but had some additions. It was so arranged that one could note the progress of the case from day to day at a glance. He expressed the hope that the president would appoint a committee to see what could be done toward getting a universal chart.

**Report of Cases.**—Dr. Joseph Roby of Rochester reported three cases. Two of these showed the effect of pneumothorax on children. The charts exhibited in connection with these cases showed the drop in temperature after the institution of the nitrogen compression treatment. The third case was one of leucemia in an adult and showed the possibilities of the *x*-ray and benzol in the treatment of this condition.

**A Case of Anorexia Nervosa in an Infant.**—Dr. Norris G. Orchard of Rochester reported this case. A child about one year of age, apparently in normal health, was given a new nipple and refused to take food afterward. Every possible method was employed to persuade the child to eat and all kinds of food were offered, but the child persistently refused to eat until he had lost about 3 pounds. At length gavage was instituted and carried out for several days after which the child again began to take his food in the usual way.

Dr. De Witt H. Sherman of Buffalo related an instance in which a child refused food and finally died, but he said he had not dignified the trouble by the name "anorexia nervosa."

## NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, Held April 3, 1913.*

The President, Dr. William M. Polk, in the Chair.

This meeting was arranged by the Section on Neurology and Psychiatry and the order of the evening was a consideration of psychological problems in medicine.

**The Psychological Clinic.**—Prof. Lightner Witmer, Ph.D., University of Pennsylvania, Philadelphia, spoke of the work of the psychologists. In bringing this branch of science before them he said he necessarily spoke with modesty and hesitation. Those present might not know that Dr. Henry W. Cattell had the distinguished honor of being the first man appointed as professor of psychology in any institution in this country; he was designated by this title in 1899. The first laboratory of psychology in this country was started by Dr. Hall of the Johns Hopkins University in 1882 and not long after men began to turn their attention to practical applications of this branch of science. Professor Witmer said he took pleasure in recognizing before the Academy of Medicine the obligations they owed to a physician of Philadelphia who first drew their attention to the relation between adenoids and defective mental development. In December, 1896, there was held at the normal school in Philadelphia a meeting of scientific men to consider the problem of the backward children in the schools, as well as the incorrigible children, with a view of establishing special classes for them if necessary. Dr. Harrison Hallett spoke of the important relation of these adenoid growths and mental deficiency. In 1896 a student of psychology in his department had under observation a boy of fourteen who was a bad speller. She was unable to teach this boy to spell. When he was examined it was learned that he could not read. After working with this boy at the Psychological Laboratory it was discovered that he was suffering from a weakness of the ocular muscles and this gave him double vision. The boy could direct his eyes upon a letter and see it distinctly, but he could not get over five or six letters in order to get the word. This boy was one of normal intelligence, but he was not able to read better than a child in the second school year. As soon as an oculist had corrected his vision his mental condition was distinctly corrected although he had some alexia. The task of teaching a boy of fourteen or fifteen what was ordinarily acquired by a child of six or seven was a long one. The boy subsequently acquired the ability to read novels and other books with a fair rapidity. He never overcame, however, the arrest of development of the brain which was due to neglect on the part of the teachers and the medical inspectors who failed to discover the relation between this physical and mental defect. Professor Witmer reported a few cases, those that specially interested him at the Psychological Clinic at the University of Pennsylvania. On the staff there they had five assistants; also a paid social worker whose duty it was to supervise the child; she had two assistant social workers. She had other duties, such as keeping records, doing stenographic work, handling the correspondence, etc. As a result of this work, and the work they were doing in the public schools of Philadelphia, he believed they could draw a sharp line of distinction between two kinds of cases and it was this problem which more interested him. There was the child who was called the feeble-minded child, the mentally deficient child, the one who belonged in institutions. Then there was the child with a mental defect, but not properly speaking one that could be called mentally defective. It was not right to call a child mentally defective when he had but a mental defect, any more than it was right to call a child physically defective because he had but one physical defect. A child with shyness, extreme obstinacy, etc., could not be called mentally defective, although this was a mental defect. Of primary interest to them were the children with mental defects, and not especially the mentally defectives. In 1911-1912 it was found that 53 per cent. of the children in the schools belonged to the class grouped as backward, and 37 per cent. were children who were classed as mentally defective. Professor Witmer believed that the most interesting problem the psychologist and physician had to deal with pertained to the children with mental defects. He believed too that this was not a problem for the public schools to deal with: these children belonged to institutions—they should be placed behind the walls of some institution. The child who was backward or retarded in school work by reason of some physical or mental defect was worthy of the most careful care and attention they could give in their public schools, and it was for them that special classes were established. The children with mental defects were far more numerous than children belonging to the mentally defective class. There was no child in fact but had one or more mental defect. These children who were retarded in their school work were so retarded because of certain conditions, by virtue of environment, or neglect, or by virtue of inadequate school training; when they reached adult age, or the age when they were compelled to go to work, their natural endowments were less developed than they might have been if they had had adequate training, the care that should be given every individual who suffered from retardation. A child might be sent home because he suffered from retardation; he might be excluded from the class because he was backward. He must be placed in a separate class. He believed that the work they were doing in the study of children was leading them to the employment of right methods, not only for those who stood at the bottom of the class, but for those who stood at the top as well. They believed that the child with the largest endowment of brains should receive the same careful attention as the one with less endowment. From a study of those causes producing retardation in children, the cases in which this retardation was very manifest, they could make the next step forward and study the exceptionally bright child. In the Philadelphia schools they had side by side the mentally defective child and the bright child. In order to give his listeners an idea of the child with a defect he ran over the history of a few cases.

Prof. K. Heilbronner of the University of Utrecht spoke in German of the work that was being done among these children in Germany.

**The Diagnosis of Mental Defects.**—H. H. Goddard, Ph.D., of Vineland, N. J., said that feeble-mindedness and mental deficiency could be defined as a condition of weak mentality existing from birth or early age whereby the individual was unable to compete with his fellows in the struggle for existence, and this definition was based upon practical every day tests. They were speaking of people so lacking in intelligence that they could not take their

places in working for an existence and were entirely different or unlike those Professor Witmer had described. They were not people who suffered from adenoids, or who were deaf, or who had eye defects and other things *per se.* They might have troubles the same as other human beings might have. These were the people who had physical organs as good as any of them, but they lacked mental capacity and just what caused this lack of mental capacity no one at present knew. They had families with different strains of intelligence or levels of intelligence. They had the famous families who might be traced back from generation to generation, members with a high plane of intelligence. This intelligence had been transmitted from father and mother to son and daughter. Then there were members of a family with average intelligence; they had been always of just about such an intelligence. Then they might recognize precisely in the same way a group of people with a strain of intelligence that was just too low to enable them to functionate as normal individuals in society, to enable them to compete with the rest in the struggle for existence and to live a normal decent life. It was this group of people they needed to understand and recognize and pick out. Why? If they were not picked out, if they were not recognized, they and all the rest of the people would insist upon placing on these people responsibilities which they could not bear and under which they would break down and they would do injury to their entire society and community. In other words, they would become dangerous and evil people. Every one who belonged to these strains, or the strain just below the level which marked them, was a potential criminal. Why should they recognize and diagnose these cases? Because if diagnosed early they could take care of them and save them from this life of criminality, pauperism or debauchery. How could they diagnose them? Here the difficulty was very great because in the first place they obviously were of normal appearance and in the second place it was difficult for the physician to recognize these cases because perhaps they were so accustomed to seeing people improve from various physical conditions that appeared to make them appear dull and stupid that they became optimistic and could not help feeling that because these people looked like the rest of them their condition would pass over and the members of the family would say "the doctor will take care of it." But as to the actual diagnosis of these cases, the complete and sure diagnosis could only be made by specialists or by those who had studied this problem. He said he had seen people who had this experience go into a school and look over and examine this and that child, and these people had been questioned, "who told you my dullest pupils?" That they were the dullest was proven to be true. The highest efficiency in this respect was realized by the ladies; they seemed to be able to more carefully scrutinize these people than did the men. He said he had two or three ladies at Vineland who were far ahead of him in this particular. This was one of the essentials in making a diagnosis. Dr. Goddard said he came for the purpose of telling them things, or making suggestions to them, which might be helpful. They as physicians had been given a great opportunity in this line of work. The fact that a child or an individual looked well should not be taken as indicating that he or she was all right. If an apparently normal child could not keep up with his fellows when he attended school, but fell backward, there was something wrong, and this should be inquired into. Take for instance a child with malnutrition; say he was a child nine years of age but with a mentality of a child of four or five; this showed that he was suffering from malnutrition and kept back in his work because of it. Perhaps he took tea and coffee for breakfast, dinner, and supper, and they might think this was the cause. But no. No part of the body was more resistant to starvation than the nervous system, and it was not safe to say that if they fed up the boy he would become normal and satisfactory. The point was this. When a child was brought to their attention who was two or three years behind in his work they should not let other things switch them from the conclusion that the child was feebleminded; they had no more right to withhold this diagnosis than if they were dealing with a suspected case of smallpox. It was a serious matter to make a wrong diagnosis in cases of feeble mindedness. Dr. Goddard then showed pictures to substantiate what he had said, and also charts showing the relationship of heredity, not only of the individuals, but of the family and of the ancestors as well.

**Genetic Psychology.**—Prof. Will S. Monroe, Ph.D., State Normal School, Montclair, N. J., told of what was being done with both the normal and the abnormal children. In the public schools many children passed through without being recognized as mentally defective and those in charge of such children should be trained to recognize them. A large number of children necessarily were handled, and some sort of instruction should be given the teachers to enable them to pick the abnormal from the normal. It was their purpose to point out the characteristics of the abnormal as well as the normal child. The child's mind acted differently from the grown mind, a fact that should be remembered in the study of genetic psychology. For instance, a child of six years, in his efforts at gaining information, reacted differently from a boy of ten years, and a mind of a child of ten years reacted differently from one of fourteen years. Again, a boy of ten years differed in this same respect from a girl of the same age. The development processes in the child must be recognized, both the normal and the abnormal. A second problem was how to bring the teachers face to face with abnormalities, to teach them how to deal with as well as how to diagnose the mental defectives. A great deal of trouble had been given them in the study of the borderline cases.

Charles F. Little, Medical Superintendent Letchworth Village, said that Professor Witmer seemed to be working in a field that was quite different from the one he was working in; he spoke of the special class of cases met with in public schools. In institutions at least they did not see these cases that were particularly improved because of the removal of adenoids, or the correction of some of the defects he mentioned. There certainly was an interesting field for work in the public schools where the cases could be handled without going into institutions. With regard to special classes for defectives, if the time came when public sentiment would force the parents to place their defective children in institutions, and if the time came when the State could and would raise money to establish enough institutions for the care of all the defectives, then it would be time to talk of handling these children and establishing ungraded classes. With regard to Dr. Goddard's remarks about the diagnosis of mental defects he believed the Binet test was of great assistance, and the more he used it the more successful he became. But it seemed to him that a series of tests might be arranged, tests that were quite different from the Binet tests, that would give them the same results. In the border line cases the Binet tests were the ones most used. It was not possible to make a positive diagnosis in the difficult cases except by having a first-class history and by having the case under observation for some time. The Binet tests, when applied to a child for a series of months, or one or two years, would enable one most certainly to determine whether or not the children were feeble minded.

Dr. Max G. Schlapp said he was glad to hear what Professor Witmer said about taking these children from the public schools. He did not agree with him, however, in his statement that feeble-minded individuals had organs that were physically as well as in others for in the feebleminded there were certain conditions present. First, there might be some definite lesion of the brain; there might be some destruction of the nervous system by inflammation. Here they could account for the condition. Secondly, there was another type of cases in which the brain anatomatically was not developed on account of something interfering with the formative activity of the cells in the individual as he was developing. Thirdly, there was a group of cases in which the functional activity of the nerve cells was interfered with. These conditions were caused by definite underlying lesions, and it was up to them as medical men and chemists to find out what particular conditions were producing these formative disturbances that delayed development of the central nervous system.

Dr. L. Pierce Clark agreed with Dr. Goddard that the Binet scale was our most valuable aid in determining the intellectual standard of any given case of suspected feebleminedness. All the cases of which Dr. Goddard showed pictures were so pronounced in defective mentality by "sight alone' that case records and heredity charts hardly seemed necessary. He doubted the correctness and fairness of counting all cases of feeblemindedness potential criminals. That their mental defect spelled an after life of vagabondage, unemployment, and almshouse occupancy seemed nearer the truth, but these latter social delinquencies could not be called crimes as ordinarily understood to-day. He especially commended Dr. Goddard's excellent heredity studies but thought we were far from knowing what the determinants were that even drove the 35 per cent. of heredity-free feebleminded into this condition. It seemed possible that understanding these psychic determinants might partly illumine the pathway of prevention.

# State Medical Licensing Boards.

## STATE BOARD EXAMINATION QUESTIONS.

MEDICAL EXAMINERS OF NEW JERSEY.

*October*, 1912.

(*Concluded from page* 874.)

GYNECOLOGY.

1. Define and give findings on examination of uterine anteversion, retroflexion, retroversion, prolapse, and procidentia, and of ovaritis, salpingitis, pyosalpinx, cystocele, rectocele, and subinvolution.
2. Give symptoms of gonorrhea in the female, and conditions which may result from it.
3. Give three causes of dysmenorrhea, and treatment of each.
4. Give causes, symptoms, and pathology of ovaritis, salpingitis, metritis, and pelvic peritonitis, and give differential diagnosis between ovaritis and salpingitis.
5. Describe the clitoris, and give its function. What are adhesions of the clitoris? What symptoms may they produce, and how are they relieved?

SURGERY.

1. Give the diagnosis and method of reduction of a dislocation of the inferior maxilla.
2. Describe a transverse fracture of the patella. Give treatment.
3. Give etiology and sequelæ of suppurative middle-ear disease.
4. Give etiology, diagnosis, and treatment of septic peritonitis.
5. Give diagnosis and treatment of fracture of base of skull.
6. Give differential diagnosis between fracture of neck of humerus and dislocation of the shoulder joint.
7. Give diagnosis and treatment of a floating cartilage.
8. Where does the quadriceps extensor femoris most frequently rupture? Give symptoms and treatment.
9. Define torticollis. Give treatment.
10. What is shock and how should it be treated?

HYGIENE.

1. What is hygiene, and how does it differ from sanitation?
2. What are the most important factors in preserving health, and how are they best observed and applied?
3. Name the contagious or infectious diseases and give in detail the best methods for preventing their spread in a community.
4. Detail the most approved method of dealing with (*a*) the patient, (*b*) the premises after any or all of such diseases.
5. Name some of the conditions that predispose to or cause disease.

JURISPRUDENCE.

1. What is the object of a coroner's inquest?
2. In cases of sudden death how would you arrive at the cause thereof?
3. Where dead bodies are taken from the water how would you determine whether the person had been drowned or not?
4. In infants, how determine whether the child had been born alive?
5. How would you conduct a post-mortem examination?

---

## ANSWERS.

GYNECOLOGY.

1. *Anteversion* is an anterior displacement of the uterus as a whole, the uterus is not bent upon itself; the fundus is found forward, and the cervix looks backward. The normal position is a slight anteversion.

*Retroflexion* is a posterior displacement of the uterus, in which the uterus is bent upon itself. The cervix is low in the pelvis, and the fundus in the cul-de-sac of Douglas.

*Retroversion* is a posterior displacement of the uterus, in which the uterus is not bent upon itself. The cervix is displaced toward the pubes, and the body of the uterus is in the hollow of the sacrum.

*Prolapse* is a downward displacement of the uterus as a whole; the cervix is felt just inside the vagina. A similar condition, but with the uterus protruding through the vagina, is called *Procidentia.*

*Ovaritis* is an inflammation of the ovary. The ovary is increased in size, is tender on pressure, and pressure cause a sickening sensation.

*Salpingitis* is inflammation of the fallopian tube. Both tubes are apt to be affected; the tube is oblong and generally adherent and the ovary may be palpated or distinct from the tumor; it is not usually very large, and there may be leucocytosis. Pain is present, and is made worse by pressure, examinations, etc.

*Pyosalpinx* is a pus tube, or abscess in the fallopian tube. The condition is the same as salpingitis with the addition of the presence of pus; hence chill, fever, and leucocytosis are added.

*Cystocele* is a hernia of part of the bladder into the vagina covered by the mucous membrane of the anterior vaginal wall.

*Rectocele* is a hernia of the rectum into the vagina, covered by the mucous membrane of the posterior vaginal wall.

*Subinvolution* is failure or delay on the part of the uterus to return to its normal condition after labor. The uterus is enlarged, soft, boggy, generally retroverted or prolapsed, and there may be irregular hemorrhages.

2. GONORRHEA. *Symptoms*: Pain and burning in the vulva; pain and burning on micturition; dyspareunia; yellowish or greenish discharge, in which the gonococcus can be found; the vagina is hot, red, swollen, and tender. *Possible results*: Cystitis, urethritis, vulvitis, endometritis, salpingitis, septic peritonitis, sterility, condylomata of vulva, abscess of Bartholin's glands.

3. *Three causes of dysmenorrhea.* (1) Pelvic congestion; this requires hot douches, glycerin tampons, and regular attention to the bowels. (2) The formation and discharge of a membrane; this requires dilatation and curettage, which may have to be repeated. (3) Malpositions of the uterus; these require reposition, the use of a pessary, breaking up of adhesions, and sometimes an operation (such as hysteropexy).

4. *Acute ovaritis* is usually secondary to salpingitis, as in gonorrhea and puerperal sepsis, but may occur as a complication of the eruptive fevers. The symptoms are pain and tenderness in the ovarian region, nausea, vomiting, rise of temperature, and rapid pulse.

*Salpingitis* is usually due to infection following labor or abortion, gonorrhea, and spread of inflammation from neighboring organs.

*Symptoms:* Pain or discomfort, made worse by pressure, examination, or defecation; or colicky pains over the tube; dysmenorrhea; increased menstrual flow; tubes are found to be dilated and swollen.

*Endometritis:* The acute form is due to the introduction of septic bacteria, and is manifested by pain, constipation, irritability of bladder, rapid pulse, rise of temperature, and a profuse discharge.

*Pelvic peritonitis* is caused by infection, and is characterized by: Intense and diffuse abdominal pain, tenderness, and distention; vomiting, constipation, elevation of the temperature (103°-104° F), small, hard, rapid and wiry pulse (120-140), and increased respiration (30-40) of a painful character are also present. The dorsal decubitus with the legs and thighs drawn up is assumed. The duration is from six to nine days and the prognosis is unfavorable.

*Pathology of ovaritis:* "The follicles are chiefly affected, but the stroma is also involved. The ovary is enlarged; the Graafian follicles swell, their contents becoming cloudy; the cells of the membrana granulosa and discus becoming degenerated, the ovum breaking down and the zona pellucida getting swollen and folded. On the surface the germ epithelium may break down. There is congestion of the vessels. Exudation takes place in the stroma; small ecchymoses may form. Pus may develop in one or more centers, and may go on to form a true abscess of the ovary. In advanced cases the ovaries may become smaller, irregular, and cirrhotic. The follicles are destroyed or filled with turbid, thick, or bloody fluid."

Of *salpingitis.* "The most important changes occur in the mucosa, but all parts of the wall are usually affected at the same time. When the peritoneum covering the tube is affected it may be a localized inflammation or part of a wider affection. It leads to bending, stricture, displacement, or to adhesion of the tube to surrounding parts. Very often the inflammation spreads to the ovary. It may close the outer end by matting the fimbriæ together. When the muscular portion of the wall is affected, it becomes thicker and hard, owing to the small-celled infiltration in it; when pus is present, small loculi may be formed throughout it. When the mucosa is affected various changes are produced. Infiltration and effusion take place

into the delicate fimbriæ and into the thin layer of submucous tissue. There is congestion of the vessels. Small hemorrhages are sometimes found. There is increased mucous secretion into the lumen, and it may contain leucocytes, shed epithelial cells intact or breaking down, and, sometimes, red blood corpuscles. The epithelial lining is lost in some parts, degenerated in others, and adhesions may occur between neighboring plicæ. Sometimes the fringes may enlarge and vegetations may form in connection with them. These appear like polypi, on transverse section. The inflammation may go on to pus formation. As a result of adhesions of the mucosa, occlusion of the tube may be brought about in one or more places. If fluid continues to be poured into the lumen, the tube gets distended and the condition of hydro- or pyosalpinx is produced. In the cases in which a slow chronic interstitial change is the main one the tube may become very hard and somewhat thickened. In advanced stages an atrophy is sometimes produced as absorption occurs. The lumen may be obliterated partly or wholly by adhesion of the walls, and unobliterated portions may give rise to small cysts."

Of *metritis*. "In acute inflammation the uterus becomes enlarged, softened, and, it may be, of doughy consistence. The walls are deeply congested in all parts, and blood extravasations may be seen in parts. Inflammatory products are exuded among the muscular bundles, and in the mucosa. If pus formation has taken place, small foci are noticed throughout the wall. The muscle is softened and often pulpy. The peritoneal surface is also inflamed. Acute metritis may lead to a chronic inflammatory condition, in which thickening and hardening of the connective tissue elements prevail; or, a chronic purulent condition may be left, abscesses being present in the uterine wall, and, sometimes, in the adjacent parametrium, tubes, and ovaries. Rarely, abscess of the wall may perforate into vagina, bladder, intestines, or abdominal walls. Sometimes rapid resolution and recovery may occur. At times death occurs from the virulence of the infection causing the inflammation." (Webster's *Diseases of Women.*)

For *differential diagnosis of ovaritis and salpingitis,* see QUESTION 1. The two conditions frequently exist together.

5. The *clitoris* is a small projection just below the mons Veneris. It is the analogue of the penis in the male, but is much smaller and is not perforated by the urethra. It is composed of two corpora cavernosa, with a glans at the anterior extremity containing erectile tissue and special genital corpuscles. The glans is covered by a prepuce. Its function is concerned with coitus and sexual pleasure.

*Adhesions of the clitoris* are constrictions which bind the prepuce of the clitoris to the glans and prevent the retraction of the prepuce. The *symptoms* are various reflex disturbances, neuroses, masturbation, or morbid sexual desires. Examination will demonstrate the adhesions and show that the prepuce cannot be readily retracted. *Treatment* consists in separation of the adhesions, under local (or general) anesthesia; the prepuce is pulled back, the glans exposed, and the adhesions broken up. Carbolated vaselin is applied, and the glans is exposed frequently to prevent readhesion.

SURGERY.

1. In *dislocation of the lower jaw,* the mouth is open and cannot be closed, the jaw protrudes, saliva dribbles from the mouth, speech and swallowing are difficult, and there is a depression in front of the ear. *Treatment:* The surgeon wraps his thumb (for protection), then presses downward and backward on the lower molar teeth: as soon as the condyle is loosened the jaw is closed by pushing up the chin. A Barton bandage is applied and worn for about fourteen days.

2. In *transverse fracture of the patella,* there will be found pain, swelling, and inability to lift the limb from the bed; the fragments are widely separated and can be moved; flexion of the leg increases the gap between the fragments. The joint should be opened to clear out the blood clot and remove the tags; the fragments may be united by wire. A posterior splint with the bringing of the fragments together by adhesive plaster has been used.

3. SUPPURATIVE MIDDLE EAR DISEASE. *Etiology:* Spread of pharyngeal catarrh, adenoids, scarlet fever, tonsillitis, diphtheria. *Complications:* Inflammation of the mastoid cells, caries, necrosis, phebitis, meningitis, abscess of brain, arthritis of temporomaxillary joint, facial paralysis, thrombosis of lateral sinus.

4. "*Septic peritonitis* may arise during the puerperium, through lymphatic infection; it may be due to infection from without by an operation or an accident; to perforation of an ulcer; to gangrene of a portion of the intestine; to rupture of an abscess into the peritoneal cavity; or to migration of microorganisms through a damaged wall of the bowel. Perforation is made manifest by a chill, shock, or rapid collapse. Gas may pass into the peritoneal cavity, and if it does so the area of liver-dullness may be lessened or abolished. Symptoms and signs of hemorrhage may arise. Diffuse septic peritonitis is announced by a very rapid pulse, which is at first wiry and later gaseous; temperature which may be at times febrile, but which is apt to be subnormal or which soon becomes so; diffused abdominal pain, general tenderness, dry tongue, delirium, persistent vomiting, constipation, and collapse. Rigidity may exist and also intestinal obstruction; often, but not invariably, there is distention. In puerperal peritonitis or septic peritonitis from operation there is often no severe pain; in perforate peritonitis there is acute pain. Patients usually die within five or six days." *Treatment:* "First the initial lesion should be got rid of as quickly as possible and with the slightest possible amount of handling. For instance, we should remove a gangrenous appendix; we should close a perforation in the bowel, etc. Flushing of the peritoneal cavity with gallons of salt solution is inadvisable. It cannot thoroughly cleanse the peritoneum; it may diffuse the infection to regions that it had not previously reached, and it may tear up adhesions. Inflammatory exudate should not be removed from the intraperitoneal structures. It is nature's method of sealing the lymph-spaces; and if we remove it we open thousands of channels, previously sealed, to the dissemination of the infection. A drainage tube should be introduced through the operation wound, and a suprapubic incision should also be made, and a drainage tube be carried through this into the pelvis. When the operation is completed, the patient should be placed in the semi-erect position, which is commonly called Fowler's position. This is done in order that the intraperitoneal fluids may gravitate away from the diaphragm, where absorption is extremely rapid, and into the pelvis, where absorption is much slower. When the patient is placed in the bed quantities of warm salt solution are passed slowly into the rectum." (Da Costa's *Surgery.*)

5. FRACTURE OF BASE OF THE SKULL. The *Signs* are those of (1) injury to the brain, (2) escape of cranial contents, (3) injury of cranial nerves. (1) *Injury to the brain* may be of the nature of concussion, compression, or laceration. (2) *Escape of cranial contents,* which may be blood, cerebrospinal fluid, or rarely brain itself. 1. *Hemorrhage* manifests itself in various situations, according to the position of the fracture. In the *anterior fossa* the bleeding may be from the nose or into the orbit, or may pass back into the pharynx, be swallowed, and subsequently vomited. The eye may be pushed forward and pulsate if the cavernous sinus be ruptured. In the *middle fossa* blood usually runs from the ears; but slight bleeding from the ear may be caused by minor injuries, such as rupture of the membrana tympani, tearing of the lining of the auditory canal, and fracture of the tympanic bone. In the *posterior fossa* a hematoma may form behind the mastoid process. 2. The escape of *cerebrospinal fluid* is a certain sign that a fracture communicates with the subdural space. It may appear in the same situations as hemorrhage, but is usually found escaping from the ear owing to fracture of the petrous bone. The fluid is limpid, specific gravity 1005, with no albumin, but containing pyrocatechin, which gives the same reaction as sugar with Fehling's solution. The amount which escapes may be small or very large, but as a rule it soon ceases. (3) *Injuries to the cranial nerves* vary according to the site of fracture. That most commonly involved is the facial, in the aqueductus Fallopii, and the paralysis may come on immediately from rupture, or after two or three weeks from the pressure of callus.

*Treatment:* The chief aim of treatment is to prevent sepsis. The ear must be mopped out with an antiseptic, and then kept covered with an antiseptic dressing, as if it were a wound. The patient must then be kept quiet, the bowels opened with a purge, and an icebag applied to the head. The diet should be low, and a return to active life not permitted for six weeks. If septic meningitis occurs the patient is bound to die. (From *Aids to Surgery.*)

6. In *fracture of the surgical neck of the humerus,* the head of the humerus will be found in the glenoid cavity, but it will not rotate with the shaft; the arm will appear shorter; and crepitus and abnormal mobility will be elicited unless there is impaction.

In *dislocation of the shoulder joint*, the glenoid cavity will be empty, and the head of the bone will be found in an abnormal position; the arm will appear longer; there will be no crepitus, and no abnormal mobility.

7. *Floating cartilages* are diagnosed by synovitis, recurrent pain, and fixation of the joint; sometimes the cartilage can be felt; the locking of the joint persists so long as the foreign body is between the bones; the *x*-ray may aid in the diagnosis. *Treatment:* The foreign body should be removed under the most careful asepsis. The locking of the joint may be relieved by forced flexion and sudden extension.

8. The quadriceps extensor generally ruptures just above the patella. The symptoms are severe pain, inability to stand, walk or extend the leg; a gap may be felt above the patella. *Treatment:* Incision, and suture of the divided ends of the muscle, under aseptic precautions. Rest is necessary, and when union has occurred massage and passive motion are indicated.

9. *Torticollis* is a contraction of the sternomastoid or other cervical muscles producing deviation of the neck; the head is drawn down towards the shoulder, and the face turned upward toward the sound side. *Treatment:* Remove the cause, treat any neurosis, give antispasmodics; stretch or cut the spinal accessory nerve or posterior cervical nerves; massage; tenotomy of the sternomastoid.

10. *Shock* is the name given to a sudden and general depression of the vital powers due to some strong stimulation (such as injury or emotion) acting on the vital centers in the medulla, and producing vasomotor paralysis.

*Treatment of shock:* Place the patient in the recumbent position, with the head low, apply warmth to the body, administer a stimulant, and give a hot saline infusion; morphine, hypodermically, may be necessary for the relief of pain. Adrenalin solution is administered into the arterial system.

HYGIENE.

1. *Hygiene* is the science and art of all that concerns the preservation, promotion, and improvement of health, and the prevention of disease. *Sanitation* is that branch of hygiene which is concerned with the suppression or removal of the predisposing causes of disease; it is the practical side of a part of the subject of hygiene.

2. Health is best preserved by: Proper habits of cleanliness; regulation of diet; avoidance of all excesses; protection by suitable clothing and habitations; adequate exercise, work, and rest. Further, the proper authorities should be supported in their efforts to promote health; communicable diseases should be reported; quarantine observed; and instruction on health lines disseminated and read.

3. An *infectious* disease is one that is caused by a known microorganism; as typhoid, tuberculosis.

A *contagious* disease was formerly understood as one that was communicated by direct personal contact, as by touch, or exhalations from breath or skin; as measles, smallpox.

*Communicable diseases* are: Smallpox, gonorrhea, cerebrospinal meningitis, tuberculosis, leprosy, tetanus, diphtheria, Asiatic cholera, typhoid, bubonic plague, dysentery, malaria, syphilis, mumps, yellow fever, measles, scarlet fever, chickenpox, rubella, rheumatism, trachoma.

To *prevent their spread:* They should be reported to the health authorities; adequate isolation and quarantine (when necessary) should be enforced; proper prophylactic measures (as vaccination) should be ordered; children, from houses where there is such disease, should not be allowed to mingle with other children; proper disposal should be made of sputum and excreta; details for each disease can be learned from special manuals on the subject.

4. "When the patient has recovered from an infectious disease, he should be given a general bath with soap and water. In addition to this, he may be bathed with chlorinated soda solution, and in the exanthemata it may be advisable to anoint his body again unless all desquamation has ceased. After a general bath has been given the patient may be allowed to mingle with the well. In most localities the convalescent from certain diseases, especially smallpox, is washed with 1:2000 bichloride of mercury solution, clothed with clean clothing, and then transferred to a disinfected room.

"The clothing and bedding which are to be disinfected by means of steam should be carefully wrapped in cloths saturated with 1 per cent. carbolic solution, placed in a wagon, and taken to the disinfecting station. After the bed has been stripped, all refuse matter, paper, and articles of little value are wrapped in cloths saturated with carbolic acid and burned in a stove or furnace. The floor, doors, windows, furniture, and the walls for a distance of 1½ meters from the floor should be washed with 5 per cent. carbolic acid solution. The walls and ceiling of the room should subsequently be sprayed with 1:1000 bichloride of mercury solution. If the walls are papered, it is advisable to remove carefully the paper before beginning the disinfection. The room is then closed as tightly as possible and disinfected by means of formaldehyde." (Bergey's *Hygiene.*)

5. *Predisposing causes of disease:* Age, sex, heredity, temperament, idiosyncrasy, diathesis, race, hygienic conditions, occupation, climate, habits (particularly with regard to food, alcohol, excesses, exposure), and present condition of health and vitality.

JURISPRUDENCE.

1. The object of a coroner's inquest is to discover the cause of death in every case where such cause is unknown, or where the circumstances attending such death are suspicious.

2. Unless I had been attending the patient prior to his death, and knew him to be suffering from a diseased condition which was likely to end in sudden death, I should advise a postmortem examination. In any case, the coroner might order such an examination.

3. In *death by drowning:* The surface is pallid, the face appears tranquil, the eyes and mouth being partly open. The skin often has the appearance known as gooseskin, and, if the body has lain upward of twelve hours in the water, that of the hands and the feet is sodden by imbibition. The most important external sign is the presence on the mouth and nostrils of a fine froth (possibly blood stained) composed of air, mucus, and the medium in which drowning took place; if the body remains three or four days in water the froth disappears. Exceptionally, fragments of weeds or other small objects may be found tightly grasped in the hands. On opening the thorax, the lungs, gray in color, with reddish staining, are seen to be very voluminous, a condition known as ballooning, partly due to infiltration of the lung tissue with some of the medium in which drowning took place, and partly to true edema. The lung substance is inelastic and pits on pressure. On section, fluid and froth resembling that found on the lips exude from the divided air passages. Minute subpleural hemorrhages are not infrequently present, and the pleural cavities may contain fluid. The stomach often contains water or other liquid which was involuntarily swallowed during attempts at respiration. Occasionally some of this fluid is forced by vital action into the intestines. With one exception, the remaining appearances are those met with after death from asphyxia. The exception is constituted by the blood, which is not only dark colored and fluid, as is usual after death from asphyxia, but is also diluted by the imbibition of water from the stomach and lungs. (From Quain's *Dictionary of Medicine.*)

4. If respiration has taken place, its lungs will float on being put into water; if respiration has not taken place, the lungs will sink. Further, the lungs before respiration are situated at the back of the thorax and do not fill the cavity; whereas, after respiration they fill the whole cavity.

5. Reference must be made to a large textbook on Pathology or Medical Jurisprudence: the answer is too long for insertion here.

---

**Typhoid Pleurisy.**—Luciano Meoni reports four cases of this condition and reviews the literature of the subject. Pleurisy is not a rare complication of typhoid fever. The serous form may be developed early or late in this disease. The hemorrhagic variety is occasionlly found. The purulent form is not uncommon; the pus may contain the bacillus of Eberth in a pure state or in association with other microorganisms. The dry and the serous forms of typhoid pleurisy run a brief course and result in recovery, while the purulent form is protracted and generally terminates with a fatal outcome. The author describes a simple non-surgical method of treatment which he employed successfully in one of his purulent cases. After aspiration of the pus he washed out the pleural cavity with a one to one thousand aqueous solution of salicylic acid. This procedure was repeated later on two occasions, as the purulent exudate formed again. The patient made a complete recovery.—*Rivista Critica di Clinica Medica.*

**The Title of "Doctor."**—The Royal College of Physicians of London now permits its licentiates to style themselves "doctor" on doorplates, visiting cards, etc. This is only a courtesy or professional title as distinguished from "doctor of medicine," which is an academic one.—*The Lancet.*

## Miscellany.

Plague Banners.—R. Crawfurd states that the custom of carrying sacred pictures in penitential processions, in times of pestilence, is one of some antiquity. If one may trust the tradition of the Church, which Jacobus de Voragine, Archbishop of Genoa, embodied in his Legenda Aurea at the end of the thirteenth century, it is at least as old as the time of Gregory the Great. Writing of that fierce outbreak of bubonic plague in Rome in 590 A.D., in which the pandemic of fifty years' duration discharged all its expiring virulence, the Archbishop says: "And because the mortality ceased not, he ordained a procession, in which he did do bear an image of our Lady, which, as is said, S. Luke the Evangelist made, which was a good painter, he had carved and painted it after the likeness of the glorious Virgin Mary. And anon the mortality ceased, and the air became pure and clear, and about the image was heard a voice of angels that sung the anthem, "Regina Coeli." At the same time S. Gregory saw an angel upon a castle, which made clean a sword all bloody, and put it into the sheath, and thereby S. Gregory understood that the pestilence of this mortality was passed, and after that it was called the Castle Angel (Castel S. Angelo)." The plague banners, or *gonfaloni* of Perugia, serve to show a lineage far older than the epoch of the Perugian School of Painting, and one that extends also beyond the boundaries of Umbria. It is only in a limited sense that they can be regarded as exclusive products of the Umbrian School, and particularly of its Perugian branch. Indeed, the two most famous had actually a Tuscan *provenance*. It so happened that the most fertile period of Perugian painting, in the latter half of the fifteenth century, coincided with the devastation of Perugia by a succession of epidemics of plague; and at each fresh outburst the painters of Perugia were called upon to produce these tributes of popular devotion. Before these suppliant banners marched the priesthood in their robes, behind them followed a penitent people, striking their breasts and wailing aloud "Misericordia." The remedy was well adapted to their sufferings, for these processions of penitents traversing the city and following banners that displayed the figure of the Redeemer, or the Madonna, or some plague saint, produced in their souls such a degree of spiritual exaltation as made despondency impossible. Men gazed on them as they gazed on the Brazen Serpent that Moses set up in the wilderness to stay the pestilence. The greatest of all the plague banners was destined to be also the last; Raphael's Sistine Madonna, in which the Madonna and Child are attended by S. Sixtus and S. Barbara, was painted during an epidemic of plague for the Black Friars of S. Sisto at Piacenza. No record exists that it was ever actually used for the purpose for which it was painted. Bonfigli, in the spirit of Phidias, had painted Mary the Queen of Heaven. Raphael, in the spirit of Praxiteles, had painted Mary the Mother of God. The people wanted a queen, and Raphael gave them a peasant woman. They could not see, as Raphael saw, in womanhood the embodiment of gentleness spiritualizing the brute in man. They could not see in motherhood the vision of willing suffering transfigured to joy. It was this reunion of Art with Nature that dethroned the plague banner.—*Proceedings of the Royal Society of Medicine*, February, 1913.

### THE CLINICAL EVIDENCE OF LYMPHURIA.*

By HEINRICH STERN, M.D.,

NEW YORK.

THERE are many cases of albuminuria, preeminently those designated as postural, cyclic, adolescent, and compensatory, in which a renal lesion may positively be excluded.† The query now arises: is the albumin in these conditions really derived from the serum and does it filter through the kidneys? In some future communications I shall try to give a detailed answer to this entire question; on this occasion I shall content myself with answering its first half.

There is abundant proof that in a certain proportion of instances of these forms of albuminuria the proteid body has reached some part of the urinary tract through the numerous lymph channels communicating with it, and that it is lymph-albumin and not serum-albumin to which the albuminuric phenomenon must be ascribed, or, in other words, that notwithstanding their identical chemical structure, the proteid substance in lymphuria has never formed a constituent of the blood plasma.

My attention was first drawn to the possibility of the occurrence of lymph in the urine some years ago when examining a number of specimens of chylous urine derived from one person. After exercise, this urine generally showed a slight milky turbescence and contained decidedly more albuminous than fatty material. The specimens obtained after from eight to ten hours' rest in bed were invariably clear and exhibited either no fat or proteid at all, or but in minute traces only. This concurrence of fat and proteid excretion, the synchronous appearance and disappearance of these substances in and from the urine, compelled me to assume that they resulted from the self-same cause, *i.e.* the admixture of chyle or lymph with the urine.

Although we are wont to differentiate between chyle and lymph, no discrepancy of this sort exists in the fasting animal. It is only after ingestion of food that the chyle differs from the lymph on account of its abundance of minutely divided fat particles. On the other hand, the lymph may occasionally become so rich in fat as to resemble chyle. Clinically, therefore, chyle and lymph are identical, but I shall designate the presence in the urine of either when rich in albuminous material as lymphuria, especially when accompanied by a comparatively large amount of young leucocytes. The quantity of albumin contained in lymph varies between three and four per cent., that is, it occurs in about the same proportion as in the blood plasma. The lymph of the liver is especially rich in albumin. Lymph-albumin is chemically not distinguishable from serum albumin. Other proteids, however, like globulin and fibrinogen, exist in the lymph in markedly smaller proportions than in the blood. Inasmuch as no serum-albuminuria ensues without a concomitant globulinuria (though the ratio of the globulin to the serum albumin is not a definite one) and the globulin excretion in lymphuria is a widely divergent and always negligible factor, the former may be recognized by the identification of the globulin and the determination of its percentage-rate.

The number of erythrocytes contained in lymph is insignificant, and there are practically no red cells to be found in a weak dilution of lymph, as in lymphuria. The leucocytes, on the other hand, always occur in the lymph in larger numbers than in the blood. The leucocyte content, however, fluctuates greatly. At times, especially some hours after the intake of food, it may attain four or five times the figure of the blood leucocytes. It is evident that the excretion of lymph-albumin cannot ensue without the simultaneous excretion of the leucocytic lymph elements. Lymphuria, therefore, is always characterized by the presence of lymphocytes, that is, clinically speaking, of well-constituted leucocytes, or of "pus corpuscles," as they are often wrongly styled. Genuine pus corpuscles are old or deteriorated leucocytes, and are never met with in the urine unless accompanied by a sufficient number of form elements indicating destructive changes in some part of the genito-urinary system. In the condition looked upon by me as simple lymphuria, evidences of an inflammatory process in the urogenital tract are entirely lacking. It is feasible, though, that certain lymphuric states may arise as a result or complication of organic disease in the urinary apparatus. The recognition of such an eventuality from the microscopical standpoint alone would, of course, be very difficult. When such complications are suspected the globulin determination must be resorted to. Generally speaking, the number of lymphocytes in a urine corresponds to its content of lymph-albumin; in other words, the greater the ratio of the cellular elements of the lymph the more intense is the albuminuria.

While non-infectious chyluria, or even lipuria in the narrower sense, is a rare condition, simple lymphuria appears to be a comparatively frequent phenomenon. None of the theories thus far advanced to explain the cause and mechanism of the juvenile albuminurias are really satisfactory. They all assume without giving any proof whatever that the albumin must of necessity have been derived from the blood, but they are all in accord that the kidneys are not in the least affected, that the

*Read before the Medical Association of the Greater City of New York, March 17, 1913.

†Stern, Heinrich: Article on Albuminuria in "Reference Handbook of the Medical Sciences," 1913.

phenomenon is of an intermittent character, and that it permits of a favorable prognosis. Recent investigations concerning the renal lymph channels have demonstrated their large number and intimate connection with the uriniferous tubules. Besides, the lymph vessels in the mucosa of the ureters and bladder communicate with the outer epithelial layers of these organs, and may readily transmit their contents to the urine. Thus, the anatomical relations, the least to say, do not avert the direct excretion of lymph into the already formed urine.

The reason now why not every individual exhibits a lymphuria is that the functional activity of his intestinal lymphatic system is not interfered with, the cause of the lymphuria resolving itself into one of pathological physiology. Overfilled intestinal lymphatics exhibiting high tension within are without doubt the direct forerunners of the lymphuria. It may be a localized or general intestinal atony and its consequences, or certain postural conditions, a compression, torsion or kink of one of the larger lymph vessels, that stands at the foundation of the lymph stasis. The lymph which cannot flow through the larger vessels slowly forces its bulk through narrow and tortuous collateral channels, and thus a portion of it will eventually be excreted into some part of the urinary tract. A patent communicating channel admitting clinically demonstrable amounts of lymph once established, the lymphuria may become a more or less regular phenomenon even when its original causative factors have ceased to exist.

The excretion of lymph into and with the urine forms only a certain, as yet undeterminable proportion of the juvenile albuminurias. However, it occurs much more frequently than the uninitiated may surmise.

The purpose of this preliminary sketch is to put lymphuria* on a clinically demonstrable basis, maintaining: First, that serum-albuminuria concurs with its inevitable globulinuria; second, that there is no or but a negligible globulinuria associated with lymphuria; third, that lymphuria occurs without any evidence of renal damage; fourth, that an intermittent juvenile albuminuria without demonstrable inflammatory products but exhibiting more or less numerous well-constituted lymphocytes, points to the presence of lymph in the urine. When in addition to the chemico-microscopical findings the patient is affected with intestinal disease or habitual constipation; when he shows evidences of a lymph stasis, enlarged tonsils, much adenoid tissue and palpable lymph nodules; and when he is anemic, easily exhausted, and averse to bodily exercise, a diagnosis of lymphuria is justified.

*It was Quincke ("Krankheiten d. Lymphgefässe" in Ziemssens Handbuch d. spez. Pathol. u. Therapie, First Ed., Vol. VI., p. 624, and *Münchener med. Wochenschr.*, June 18, 1912) who, in a rather tentative and academic manner first drew attention to the possibility of a urinary lymph excretion.

250 West Seventy-third Street.

**Action of Suprarenal Extract upon the Respiration.**—F. Pentimalli has found that the intravenous injection of suprarenal extract into rabbits causes a diminution in the frequency and depth of respiration, but direct application of this substance to the nervous centers has no influence upon the respiratory function. The explanation of this difference of action is the following: The effect upon breathing is due to anemia of the respiratory center resulting from vasoconstriction. Direct application of the suprarenal extract to the medulla oblongata does not, however, produce a degree of anemia equal to that resulting from the intravenous injection.—*Archivio per le Scienze Mediche.*

## COLON BACILLUS INFECTION OF THE KIDNEY.*

By WINFIELD AYRES, M.D.,

NEW YORK.

Recent research has demonstrated that very many pathological conditions of the abdominal viscera are directly due to infection by colon bacilli. Were we to consider these infections only, one might be led to believe that such inflammations were due to contiguity, but colon bacillus infections occur in other parts of the body and are unquestionably of hematogenous origin and we will have to conclude that the colon bacillus is like all other germs we have to deal with, and infection by this organism is through the blood in nearly all cases. Especially is this so in regard to the kidney which besides its true capsule has in addition its fatty capsule as a wall against infection by contiguity with the colon.

Predisposing causes for colon bacillus infection of the kidney are injury, congestion of the kidney, and preexisting inflammation. Under the first we find direct or indirect trauma. One of my cases occurred in a boxing instructor who was accustomed to allow his pupils to strike him repeatedly on the left side. Another had fallen a short distance, striking her left side on the back of a chair. Under congestion we may class those cases which follow confinement, operation on the pelvic organs, and renal calculus. Third, the colon bacillus is sometimes engrafted on some other infection of the kidney.

Miss H. was referred to me in January, 1910, by Dr. Ten Broeck of La Porte. She had consulted him in September, 1909, and he had found a colon bacillus infection of her left kidney. He treated her by pelvic lavage and vaccines until January, 1910, and then, though he did not consider her absolutely cured, advised her to go to work and come to me for treatment. On examination I could find no trace of colon bacilli, but did find acid-fast bacilli. Of course there is a question whether the original infection was tubercle or colon bacillus, but from the examination and subsequent course of the disease it seemed hardly probable that a tuberculous process so chronic in character could have existed so short a time and in my opinion the colon bacillus was engrafted on a tuberculous infection and covered it for the time being so that when she first consulted Dr. Ten Broeck no evidence of tuberculous infection could be found. In another case, a young man came to the Post-Graduate Dispensary suffering from gonococci infection of the right renal pelvis. (Gram-negative intracellular diplococci were found in a specimen of urine taken by ureteral catheter from his right kidney, but no culture was made.) He was at once sent to bed in the hospital and hot local applications were applied over the affected kidney and he was given urinary antiseptics. Five days later he developed pyohydronephrosis and when I opened the kidney the characteristic odor of the colon bacillus was encountered. Gram-negative bacilli, but no diplococci were found in the pus. And fourth, we encounter some cases in which no predisposing cause can be found.

Primary colon bacillus infection of the kidney is usually ushered in with a slight chill or chilly sensations and the fever is not as a rule high. There may or may not be pain in the region of the kidney. Usually the only symptom complained of is great

*Read before the Medical Association of the Greater City of New York, March 17, 1913.

irritability of the bladder. Slight chills occur at irregular intervals and the fever fluctuates between 99 and 102, indicating a low grade septic infection, but in the more severe forms the temperature may go as high as 106 and be accompanied by delirium. Very rarely does spontaneous recovery occur, but if the condition is not recognized it tends to persist indefinitely with partial or complete destruction of the kidney. In other cases we find a calculus partly blocking the ureter at the pelvis and we get enormous collections of pus. Mrs. T., seen four years ago, had a very large tumor on the left side which simulated an enlarged spleen. The ureteral catheter drew off pure pus and when the kidney was opened fully 16 ounces of pus was found in the pelvis. It is a peculiar phenomenon that only very rarely is there the characteristic odor to the voided urine, but when the kidney is opened this odor is often encountered.

Diagnosis must be made by culture, as our old ideas that the colon bacillus is easily recognized by the microscope have been proven wrong. Given a patient with subjective symptoms of cystitis, pus in the urine, and running a septic temperature, the kidney should be the first organ suspected. The patient's urine must be examined microscopically and if Gram-negative bacilli are found a culture should be made. Palpation of the kidney will often reveal an enlargement, and often the swelling is so slight as to be imperceptible to touch. A radiograph is sometimes of value, but usually a kidney which is so little enlarged as to be undetected by palpation will show nothing on the plate. It must be remembered that inflammation of the internal genitals, both male and female, when associated with cystitis, often causes symptoms simulating infection of the kidney. Neither may we overlook the fact that a patient suffering from inflammation of the bladder may have some cause outside the urinary tract which is causing the fever. And on the other hand we may have pyonephrosis at the same time that we have malaria, typhoid, etc. It is a well established fact that in any case of persistent pyuria the kidneys must be investigated. Catheterization of the ureters is the only method of making a positive diagnosis of renal pyuria unless the urine issuing from the affected side be very cloudy. Observation of the ureteral orifices leaves one often in doubt whether the urinary jet is cloudy or not; also a phosphaturia may give the impression of renal pyuria. Microscopic examination of the collection from each side is the only criterion, and should pus and Gram-negative bacilli be found, a culture is made to demonstrate positively the nature of the infection.

As soon as it is suspected that one or both kidneys are inflamed, the patient should be kept in bed and hot applications made over the affected side. Hexamethylenamin is our main reliance as a urinary antiseptic and it must be pushed until free formaldehyde is detected in the urine or until 100 or 120 grains are given in 24 hours. If under this dosage no formaldehyde can be detected in the urine, the drug is stopped because, though it is found in the urine, it has no germicidal action whatever. It has been found that in some patients formaldehyde can be detected when only 7.5 grains have been taken, while in others very much larger doses are required before any trace of the gas shows. This will explain why we sometimes see great irritability of the urinary organs from small doses and the next patient is able to take the highest dosage with no irritation. Fortunately when we are giving the large dosage, formaldehyde appears in the urine gradually and there is no sudden breaking down of the full amount given otherwise we would have intense poisoning by formaldehyde.

The Hehner test for formaldehyde does not distinguish it from hexamethylenamin, but Burnam has developed such a test, as follows: "Add to the suspected fluid three drops of a five-tenths per cent. aqueous solution of phenylhydrazine hydrochloride and then three drops of a five per cent. aqueous solution of sodium nitroprusside, then an excess of a saturated aqueous solution of sodium hydroxide. When formaldehyde is present in a solution of 1 to 20,000 or stronger, there follows an intense blue color which gradually changes to green and then after a few minutes to brown." Here we have a test which guides us in determining the amount of hexamethylenamin to give, and also tells us whether there is any use in continuing the drug. Burnam in his tests showed that in certain cases free formaldehyde could not be found in the urine until very large doses were given and in other cases it was not found at any time during its administration. And he also proved when it was not broken up, hexamethylenamin could be given in enormous doses without the slightest irritation or benefit. He also found that it was broken up in an alkaline almost as well as in an acid urine.

The method of giving hexamethylenamin is to begin with 7.5 grains t.i.d., each day testing for formaldehyde, and, until it is found, increasing the dosage of medicine rapidly up to 100 or 120 grains a day. If formaldehyde is not detected in the urine when the maximum dose is reached the drug should be stopped and some other urinary antiseptic—sodium benzoate or salol—tried. A peculiar phenomenon has been noted in the administration of hexamethylenamin, namely, when it is given in full doses and the urinary examination has shown a fairly large percentage of formaldehyde, though there may have been no appreciable benefit from its administration, yet when the medicine is stopped all symptoms at once subside in a small number of cases.

Colon bacillus vaccines have been used successfully by a number of observers, but I have never seen a case in which I thought they were indicated. Rarely is colon bacillus infection of the kidney of an acute type and therefore early operation is not often demanded. Two weeks or more should be devoted to an attempt to overcome the inflammation by the methods described before any surgical interference is considered. Having failed in our palliative methods the ureters are to be catheterized to determine the condition of both kidneys. Careful examination should be made to find if there is residual urine in the pelvis of the diseased kidney. After sufficient urine has been collected for observation the pelvis of the affected kidney should be flushed gently with hot boric acid solution until the return flow is fairly clear. If there are no abscesses in the parenchyma of the kidney, this simple wash will usually reduce the size of the kidney to a marked degree and the fever and subjective symptoms will subside. Provided there is good drainage from the pelvis, such a case will entirely recover under pelvic lavage. On the other hand, if we find residual urine in the renal pelvis, though the kidney may reduce in size and all subjective symptoms disappear, the patient will never be free of pyuria until the kidney has been removed. In the writer's opinion it makes very little difference what antiseptic is

used, the benefit derived being the mechanical action of dilating and stimulating the ureter by the passage of the ureteral catheter, cleansing the renal pelvis of the products of inflammation, and the benefit of a hot douch bathing the pyramids of the kidney. As a matter of routine boric acid is used for the tentative wash and if it is determined to continue lavage, silver nitrate, in mild solution, is used at later sittings. Koll, of Chicago, claims specific anti-colon-bacillus action from a 2 per cent. solution of liquor plumbi acetatis.

Should the onset of infection be severe, or should the tentative lavage fail to benefit the patient, nephrotomy is indicated and when the kidney is exposed the surgeon will then have to decide whether nephrectomy or nephrostomy is to be done. In all those cases in which the renal pelvis does not drain properly nephrectomy is indicated unless a plastic operation can be done on the upper extremity of the ureter. If for any reason nephrectomy is contraindicated in the latter type of cases, pelvic lavage once or twice a week will sufficiently clean the renal pelvis as to keep the patient comfortable.

616 Madison Avenue.

## PROSTITUTION IN NEW YORK CITY;

### A STUDY IN SOCIAL HYGIENE.

By DOUGLAS C. McMURTRIE,

NEW YORK.

The question of prostitution in New York City, its limitation, regulation, or suppression, has lately received considerable attention from both the medical circles and the laity. The metropolis of the country, the city had developed in response to, and perhaps in excess of, the demand, a great system of organized vice, the method of dealing with which became of the greatest importance to the health and welfare of the community. Several organizations had enlisted in an effort to cope with the situation but there was lacking a thorough and comprehensive survey of prostitution in the municipality. Other cities had faced the matter, and made such surveys, as for instance Chicago, Minneapolis, and Syracuse, but New York had not been studied from the scientific viewpoint.

During the first half of the year 1910 a Special Grand Jury investigated the so-called "white slave traffic" in the vicinity of New York, and one of the recommendations made on the termination of the work was that there should be appointed a public commission for the purpose of studying the social evil. The foreman of the jury, Mr. John D. Rockefeller, Jr., after conference with various authorities, decided that a private permanent bureau might accomplish the most good. For this reason he founded the Bureau of Social Hygiene. One of the first acts of this bureau was the establishment of a Laboratory of Social Hygiene in connection with the New York State Reformatory for Women at Bedford Hills, N. Y., under the direction of Miss Katharine Bement Davis. It is proposed here to study from the physical, mental, social, and moral sides each person committed to the reformatory, with the aim of establishing improved methods of treatment.

Before starting further work the bureau very wisely decided that the first move necessary was a careful study of conditions both at home and abroad so that full advantage might be had of past experience. In January, 1912, the bureau engaged Mr. George J. Kneeland, who had previously conducted the investigations of the Chicago Vice Commission. Mr. Kneeland and a corps of assistants were directed to make a thorough and comprehensive study of the conditions of prostitution in New York City, and the findings* of this survey have just been presented. Mr. Abraham Flexner has made a study of conditions and methods of dealing with prostitution in the leading cities of Europe, and Mr. Raymond B. Fosdick is studying police systems in Europe. Reports on these studies will be made later.

The subject matter† of the first study is of sufficient interest to justify the consideration of the findings in some detail. The picture of prostitution in New York City as presented is faithful and well drawn, and it will be noted that the newer forms of prostitution are adequately described. In this connection it may be well to recall that the organized house of prostitution or brothel is no longer the exclusive manifestation of public vice. With the exigencies of varying methods of police control, the crusades of reformers, and the rise of public opinion, a large proportion of the business of prostitution has been diverted from this more or less flagrant channel into the more obscure but insidious private apartment. In this metamorphosis the telephone has played an important part. The *café chantant* and the vicious restaurant with its cabaret show have also come to play leading rôles in the system. Prostitution also exists at the present time in many different sections of the city and in many instances has honeycombed whole residence districts.

Vice Resorts.—In the report in question places in which the actual business of prostitution is carried on are designated as vice resorts. The most prominent types are the so-called parlor house or brothel (the standard house of prostitution), the furnished room house, the disorderly hotel (the two latter have generally been described as assignation houses), and the massage parlor.

The parlor house or brothel is defined by the report as a building used exclusively for prostitution. "It derives its name from the fact that its inmates gather in the parlor to receive their guests. There is, however, an exception to the definition, inasmuch as some parlor houses in New York City are situated on the upper floors of buildings the ground floors of which are used for legitimate business enterprises." The investigation lasted from January 24, 1912, to November 15, 1912, and 142 parlor houses were visited in Manhattan, to which borough the study was limited. Although not absolutely complete, this number is thought to approximate the total. Of these 20 were commonly known as fifty-cent houses, 80 as one-dollar houses, 6 as two-dollar houses, and 34 as five-and ten-dollar houses. The prices charged in the remaining two houses were unknown.

The sanitary conditions in the cheaper houses were found extremely bad. "For instance, the fifty-cent houses on the lower East Side are described as being practically unfit for human habitation. The rooms are dirty, the loose and creaking floors are covered with matting which is gradually rotting away, the ceilings are low, the windows small, the

*"Commercialized Prostitution in New York City." By George J. Kneeland, with a supplementary chapter by Katharine Bement Davis and an introduction by John D. Rockefeller, Jr. Publications of the Bureau of Social Hygiene, New York, The Century Co., 1913.

†It is to be hoped that future volumes will be improved in mechanical production, the style of the present one leaving much to be desired.

air heavy and filled with foul odors. The sanitary conditions in the majority of the one-dollar houses on the west side streets between Sixth and Seventh Avenues are hardly less objectionable. No attempt is made to keep the houses clean. The floors are rotten and filthy; they sag as one walks across them. The small bedrooms are damp and unventilated; the atmosphere is heavy with odors of tobacco and perfumes, mingled with the fumes of medicine and cheap disinfectants." Needless to say such conditions do not augur well for sexual hygiene.

Recently publicity regarding the dangers of venereal disease has had its influence on the keepers of the houses who were found alive to the importance of convincing guests regarding the freedom of the inmates from infection. In practically all the houses the investigators were told that the girls had in their possession medical certificates signed by physicians stating that the subject had been examined and was free from venereal disease. In many instances the "physician" was said to come once a week. At such times he makes a hurried and superficial examination for which he receives a fee of one dollar, half of which he returns to the keeper of the house. It is needless to comment on the value of such certificates as might be given, from the standpoint of either ethical integrity or diagnostic certainty. Interesting light will be thrown on this latter phase in a later section of this article dealing with venereal diseases.

Another type of vice resort is classified in the present report under the heading "tenement houses." This is a technical definition for what are ordinarily known as "apartments." During the investigation 1,172 different vice resorts were found in 575 different apartment houses and tenements in Manhattan. The methods and conduct of these apartments are not far different from those in the parlor houses. One exceptionally undesirable feature—and this must be remembered by those directing their efforts against the organized houses of prostitution—is the close proximity of these apartments to respectable families of the poorer class with young children in the impressionable stage of life. The report gives several incidents showing that such young children learned to understand and recognize what was going on under their eyes.

In these apartments the pretense of medical inspection as already described is also maintained.

One type of apartment is known as the "call house." Here the girls are not on the premises but are summoned over the telephone as customers arrive and express their preference as to age, appearance, style, and other characteristics. These establishments cater to an exclusive and quiet trade.

The resorts which have been so far described are fixed places where essentially the same women are concerned from time to time. There is, however, a great deal of itinerant prostitution and to accommodate this there are assignation houses or disorderly hotels and furnished room houses.

In the investigation there were found 103 hotels which were classed as being assignation places, disorderly, or suspicious. Evidence was discovered which proved that prostitutes were openly soliciting men on the street and elsewhere to go to 65 of these hotels for immoral purposes. A woman investigator discovered 25 additional hotels where prostitutes declared they could freely take customers or have them openly visit their apartments or rooms. Other hotels could be used carefully under certain conditions, and it is of course known that almost any hotel may be used without the knowledge of the management for prostitution purposes. The disorderly hotels vary greatly as regards their sanitary condition, but it may be regarded as sure that hygiene as regards changing linen and similar features is always sacrificed in the interests of economy.

Another type of assignation place is the furnished room house. In the investigation in question 112 such vice resorts were discovered.

Still another type of vice resort is the so-called massage parlor. It is estimated that there are over 300 of these in Manhattan, a large proportion of which are believed to be vice resorts. But 75, however, were actually investigated.

**Places Which Cater to Vice.**—Not only actual vice resorts are involved in the prostitution question, especially at the present time; there are also places where prostitution is promoted in various ways. The report describes such places as follows: "Places which cater to vice are divided into two groups. The first group catering directly to vice, includes saloons and their accessories, such as concert halls and cabaret shows; the second group, operating indirectly, comprises public dance halls, burlesque theaters, amusement parks, and boat excursions. The proprietors of these places usually have full knowledge of the demoralizing influence of their establishments, and deliberately encourage such conditions for the purpose of increasing their profits." There is meant, of course, the disreputable establishment in each class, there being certain exceptions.

Disorderly saloons, concert halls, and cabaret shows may all be considered together, because they are all connected with saloons, differing only in the character and grade of the entertainment. The rear rooms of 765 different saloons were investigated. Unescorted women, who from their actions and conversation were believed to be prostitutes, were seen in 308 of these and the investigators were solicited by prostitutes in 107. In some places white men and colored women, and in others colored men and white women were found to mingle intimately.

There are some miscellaneous places in New York which "cater directly to vice in that they are frequented, for the most part, by immoral and dissolute persons who not only solicit on the premises for immoral purposes, but create conditions which stimulate the business of prostitution. The proprietors have a guilty knowledge of the fact that prostitutes and their kind use the premises as an adjunct to immoral trade. Such places include restaurants, pool rooms, delicatessen stores, candy shops, hair dressing and manicure parlors, barber shops, cigar stores, palmist and clairvoyant parlors, livery stables, and opium dens. The places in question are usually situated in the vicinity of vice resorts." Reports were made in connection with conditions in 91 such places.

Street-walking and soliciting is an important factor in the New York situation. It is particularly frequent in certain well-known localities. Most of this soliciting, however, is done on Broadway as is shown by the following table:

| | All Streets in Manhattan | Broadway |
|---|---|---|
| Street-walkers counted | 6,759 | 3,175 |
| Street-walkers who solicited investigators | 793 | 235 |
| Number of reports | 1,596 | 492 |

By this it will be seen that of the total number of street-walkers counted, over 47 per cent. were on Broadway, and of the total number of street-walkers who solicited investigators, nearly 30 per cent. were on Broadway. It may be remarked that the street-walkers are generally lowest in the hygienic scale and virulently infectious as they can operate in a diseased state on the street even when they cannot remain in the houses.

The public dance halls have long been known to be prolific breeding-grounds of prostitution and no extended description of them will be necessary. Of 75 different dance halls only 5 were characterized as decent; 11 were more or less objectionable; 59 were wholly so. At all but three liquor was sold. At practically all a large proportion of the attendance was largely disreputable.

The excursion boats and parks offer certain opportunities for immorality.

In the following three tables will be found an indication of the extent of the business of prostitution in the City of New York and the range of the investigation. They will be understood to refer to the period of study, *i.e.* January 24 to November 15, 1912.

SUMMARY OF PLACES IN MANHATTAN WHERE PROSTITUTION WAS FOUND TO EXIST

| Types of Places | Number of Buildings | Different Vice Resorts in Them | Number of Investigations Made |
|---|---|---|---|
| Parlor houses | 142 | 142 | 441 |
| Massage parlors | 70 | 75 | 78 |
| Apartments | 578 | 1,172 | 1,245 |
| Furnished rooms | 112 | 112 | 148 |
| Hotels | 105 | 105 | 560 |
| Totals | 1,007 | 1,606 | 2,472 |

SUMMARY OF PLACES IN MANHATTAN CATERING TO PROSTITUTION

| Types of Places | Different Addresses of Buildings | Different Investigations Made | Number of Prostitutes Counted |
|---|---|---|---|
| Saloons, cafes and concert halls | 308 | 1,304 | 2,689 |
| Miscellaneous places allied with prostitution | 71 | 145 | 385 |
| Semi-public places used by prostitutes | 20 | 35 | 150 |
| Totals | 399 | 1,484 | 3,224 |

SUMMARY OF INMATES COUNTED AND ESTIMATED AT PLACES IN MANHATTAN WHERE PROSTITUTION WAS REPORTED

| Types of Places | Number of Inmates Counted | Inmates Estimated But Not All Seen | Total |
|---|---|---|---|
| Parlor houses | 1,686 | 2,609 | 2,609 |
| Massage parlors | 153 | | 153 |
| Apartments | 2,294 | 2,976 | 2,976 |
| Furnished rooms | 227 | .... | 227 |
| Hotels | 583 | .... | 583 |
| Totals | 4,943 | 5,585 | 6,548 |

In considering these figures as indicative of the volume of prostitution in New York City it must be remembered that women on the street have been referred to earlier in this article. While it is possible there may have been some duplication, this is more than offset by large numbers which must have remained undiscovered. It must also be borne in mind that the occasional and casual prostitution which is so frequent in New York City was not touched by the scope of the inquiry.

Widely varying estimates have been made regarding the total number of professional prostitutes in New York City. A recent estimate which was given wide publicity in the daily press placed the figure at 30,000. In the investigation under consideration there were counted in vice resorts and on the streets 14,926 professional prostitutes in the borough of Manhattan. According to the report "it is safe to say that a total of 15,000 in round numbers does not overstate the number of professional prostitues in Manhattan." This is a conservative figure: the total in the whole city is probably much larger.

Having thus gained some idea of the extent and general character of organized prostitution in New York, we may examine several phases of more particular medical interest.

**Aspects of Medical Interest.**—As in Chicago, sexually perverted practices and unnatural exhibitions have been found to play a considerable rôle in the arena of prostitution in New York. As is known a considerable proportion of the prostitutes are addicted to perverse practices among themselves and in the large cities there is a class of customers who demand satisfaction in abnormal ways. Prostitutes have found it profitable to comply with these demands. There are also a large number of men to whom exhibitions of a pornographic character strongly appeal and these also have the effect of stimulating business.

The use of drugs by prostitutes is very common. According to the report "alcohol is needed to keep the inmates to their task, but even more essential from the business standpoint are drugs. The girl must be kept gay and attractive, her eyes must look out on the world of business bright and unfaltering." In the effort to maintain this attitude many become slaves to drug habits.

**Venereal Disease.**—In the report under consideration the attention given to venereal disease is not extensive, but there is adduced some evidence of interest, particularly that bearing on the blood tests of women who had been engaged in prostitution.

Under present circumstances any effort to estimate the volume of venereal disease in a city like New York must seem vain. Without having syphilis and gonorrhea reportable the number of cases under treatment by private physicians are unknown and there are countless numbers of patients who either conceal their condition entirely or resort to quacks or advertised "cures" for relief.

The following facts will, however, be of interest. During 1911 the number of cases of all kinds treated in 17 dispensaries in New York City was 522,722. Of these, 15,781 or 3.01 per cent. were venereally infected. There is very scant hospital accommodation for the victims of syphilis and gonorrhea, yet 5,380 cases, 6.33 per cent. of all the cases treated in 13 different hospitals, were venereally infected.

Of these 5,380 patients about two-thirds were male and one-third female. The infections occurred at various times between the first and the seventieth year, the period of greatest frequency being between 16 and 30 years of age. The sex distribution in the various age groups was:

| | Male | Female | Total |
|---|---|---|---|
| Between 16 and 20 | 796 | 396 | 1,192 |
| 21 and 25 | 1,182 | 454 | 1,636 |
| 26 and 30 | 692 | 268 | 960 |

The civil state was as follows:

| | | |
|---|---|---|
| Male | Single | 640 |
| | Married | 2,950 |
| | Widowers | 67 |
| Female | Single | 589 |
| | Married | 802 |
| | Widows | 9 |

Any ordinary figures for venereal disease must be defective for several well-known reasons. One point is that accurate diagnosis has only recently become feasible. The positive diagnoses increase largely in number with the application of the more delicate and reliable tests. An example will suffice to demonstrate: 308 adults were admitted to the medical wards of a New York hospital during the months of January, February, and March, 1913. The Wassermann test for syphilis was made in 166 cases among these patients and 38, or 23 per cent. of those examined, gave positive results. This is equivalent to 12.3 per cent. of the entire 308. As the report comments "had the test been applied to all adults admitted, undoubtedly the ratio of syphilitic infection would have been higher still. As a matter of fact, the test as usually performed does not disclose all cases of infection; so that the prevalence of disease is actually greater than the tests indicate."

**Clinical Diagnosis and Blood Tests.**—A study of the records of 647 cases at the State Reformatory for Women at Bedford Hills, N. Y., showed that 20.56 per cent. had clinical manifestations of venereal disease, as set forth by the following table:

| | |
|---|---|
| Syphilis | 61 |
| Gonorrhea | 54 |
| Syphilis and gonorrhea | 9 |
| Disease unstated | 8 |
| Chancre | 1 |
| Total | 133 |

A series of complement fixation tests on blood specimens of 466 inmates was made, however, by Dr. Archibald McNeil of the Research Laboratory of the New York City Board of Health and some different results were shown. The method followed was as follows: All smears were prepared and examined in duplicate and were stained by Gram's method, pure cultures of staphylococci and colon bacilli being used as controls. It is noted, however, that in one case the smear was positive and the complement fixation test for gonorrhea was negative, but as a rule antibodies against the gonococcus do not appear in the blood during the acute stage of the disease, so it may happen that there result positive smears and negative complement fixation tests in recent cases. At a later period, however, it is noted that the complement fixation test is almost invariably positive. The complement fixation tests were all performed in duplicate as a check on any possible errors in technique. The anti-sheep hemolytic system with inactive sera was used with the alcoholic extract of guinea-pig heart for an antigen in the syphilis tests, and an antigen prepared from ten varieties of gonococci was used in the tests for gonorrhea. All of the tests were made in sets of twelve, each set being fully controlled. The blood specimens were unaccompanied by histories and the laboratory results were not in any way influenced by clinical findings.

Of the 466 cases already referred to, with the Wassermann test the following results ensued:

| | Number | Per Cent. |
|---|---|---|
| Positive reactions | 176 | 37.7 |
| Negative reactions | 273 | 58.6 |
| Doubtful reactions | 17 | 3.6 |

With a modification of the Wassermann technique the tests were allowed to stand for four hours at ice-box temperature to fix complement instead of the usual one hour in the incubator at 37° C. By this method the following results were obtained:

| | Number | Per Cent. |
|---|---|---|
| Positive reactions | 224 | 48 |
| Negative reactions | 212 | 45.4 |
| Doubtful reactions | 30 | 6.4 |

The increase of positive reactions for syphilis by the use of this modified method instead of the regular one was 10.3 per cent.

The same sera under the complement fixation test (at 37° C. for one hour) for gonorrhea infection resulted as follows:

| | Number | Per Cent. |
|---|---|---|
| Positive reactions | 134 | 29 |
| Negative reactions | 234 | 50 |
| Doubtful reactions | 98 | 21 |

With the ice-box method of fixation the following results were obtained:

| | Number | Per Cent. |
|---|---|---|
| Positive reactions | 306 | 65.6 |
| Negative reactions | 101 | 21.7 |
| Doubtful reactions | 59 | 12.6 |

The increase in positive results by this method of fixation was therefore 36.9 per cent.

By the examination of vaginal smears from the same subjects it was possible to demonstrate the presence of the gonococcus in but five cases.

The results when summarized have a wide significance and great importance. Of the 466 girls tested, only 50, or 10.7 per cent., were found to be free from venereal infection. Practically 90 per cent. showed infection, there being positive results as follows:

| | Number | Per Cent. |
|---|---|---|
| For both syphilis and gonorrhea | 170 | 36.4 |
| For syphilis only | 27 | 5.79 |
| For gonorrhea only | 117 | 25.1 |

It will be seen how hopelessly inadequate is diagnosis based on so-called clinical manifestations. From the blood tests it would seem that gonorrhea was contracted in advance of syphilis more frequently than the reverse order obtained.

**View of New York Conditions.**—This first report of the Bureau of Social Hygiene is most encouraging from a scientific point of view. It is a dispassionate though an impressive account of the situation in the metropolis and the absence of overdrawn and superlative adjectives is most commendable. As we have had so much literature upon this subject of a widely different character I cannot refrain from citing an example to illustrate my meaning. To quote from the report: "On January 20, 1912, a well-known pimp met his woman in the rear room of a saloon on Seventh Avenue. An investigator saw this prostitute give him a ten dollar bill. The pimp upbraided the girl for not having more money and struck her a heavy blow in the face. She fell to the floor. The girl was advised to have the pimp arrested, but she refused to do so although her eyes were swollen and discolored." There is no further comment; merely an accurate record of fact.

No conclusions regarding the best means of dealing with prostitution were drawn, but this enhances rather than vitiates the value of the report. One contention, however, is implied by the title—

"Commercialed Prostitution in New York City"—namely, that the prostitution system at the present time can in no way be considered as the answer to a natural demand on the part of the people. It is shown to be exploited to the last degree, using every means to create, through allied agencies of prurient influence, demands which would not otherwise exist. There is presented extensive evidence on these points and, in my opinion, the contention referred to is sustained with complete certainty.

298 Metropolitan Tower.

## A CASE OF ADDISON'S DISEASE WITH SEVERE ABDOMINAL SYMPTOMS.

By LINDSAY S. MILNE, M.D.,

ROSEDALE, KANSAS.

The following case of Addison disease illustrated the usual clinical features of this disease, but also was of more particular interest in relation to the nervous manifestations which were present. Acute abdominal symptoms such as occurred in this case, although usually mentioned in works on this subject seem to be of no uncommon occurrence in the terminal stages of Addison's disease. They are, however, very confusing, and in many cases seem to have led to a variety of mistaken diagnoses.

The following case occurred in a well developed male, twenty years of age, a traction engineer. He was originally of fair complexion, and was light haired. He came under observation complaining of intense abdominal pain, thirteen days before the date of his death. About a year previously his face began to get considerably browner in color. A month or two after this his hands and arms began to get pigmented in the same way; the feet, legs, and pubic region followed this, then the skin of the body. This pigmentation had gradually become deeper, particularly in the face and pubic region. For the last two months he had gradually been losing strength. Till this time, however, he had been working. At no time had there been any fever, sweating at night or loss of weight. Three weeks before the date of his death he developed a severe headache, was nauseated, and vomited frequently, and there was severe pain over the whole abdomen, particularly in the lower right portion. There was no diarrhea, but during this time he was considerably constipated. Two days after the onset of these symptoms he began to lose muscular strength very rapidly, and on admission to the hospital five days later was very weak indeed.

Personal history: He had measles and chickenpox as a child, but no other sickness in his life till at present. He never had syphilis. He smoked a pipe a good deal. His work had been with a threshing traction engine, since he was twelve years old. Family history: Father died of consumption; one aunt died of consumption; mother and one younger brother alive and healthy. No similar case of pigmentation in the family.

On physical examination his face and neck were very dark brown in color, so also were his head and arms. The axillary regions were deeply pigmented, and the nipples nearly black. The skin of the thorax, abdomen, and back was brown in color, but much lighter than the other portions of the body. The feet and legs were deeply pigmented, and the pubic region and genitals were almost black in color. The sclerotics were not pigmented. The mucous membrane of the mouth was somewhat brownish in color. There was no jaundice. The thyroid was not enlarged. There were no eruptions or scars on the skin, and no enlarged lymphatic glands. The chest was long, and there was a slight scoliosis. There was no dyspnea or cough. The physical examination of the chest revealed no signs of tuberculosis or other disease condition. The heart apex beat was in the fifth interspace, 3 inches from the midsternal line. The pulsation was circumscribed in a small area, and was very feeble. There was no other pulsation over the precordia, nor any pulsation in the epigastrium. The heart sounds were distant, and were short and slapping in character. The pulmonary second sound was slightly accentuated. There was no cardiac murmur. The pulse was slow, averaging 60 to 70 per minute, but regular. Its volume was small, and the blood pressure averaging 110 mm. of mercury.

He was vomiting very frequently, bringing up only small quantities of mucus. He felt continuously nauseated and faint, and preferred to lie on his back with the knees drawn up. His abdominal pain became much worse when the legs were extended. He complained of pain over the entire abdomen, worst in the right iliac and lumbar regions. This pain seemed to be continuous in character, and did not shoot in any direction. The abdomen was retracted slightly, and the skin over this region was extremely hypersensitive. No abnormal localized area of resistance could be determined in any part of the abdomen. The abdomen was fairly rigid, but moved considerably on respiration. On palpation, severe pain was elicited from pressure on any part of the abdomen, but was much worse in the right iliac and lumbar regions. His liver and spleen were not specially tender nor were they palpable. His stomach was not dilated. The large intestines were not distended. The motor power of all the muscles was weak. The reflexes were diminished. His mentality was clear and his special senses apparently were normal. The feces showed no special change. His urine had a specific gravity 1018 and contained no albumin or sugar. There was, however, a considerable deposit of triple phosphates. His temperature on admission was 95, and for the next six days varied from 97 to 98.8. During this time the pain in his abdomen continued very severely, but was never shooting in character. The abdomen was very tender and the skin extremely hypersensitive over this region. He continued lying on his back with the legs drawn up, complaining of very severe pain if moved. He frequently vomited small quantities of mucus and any food given him. Extreme nausea seemed to be present almost continuously. His bowels at first moved once daily and enemas gave fairly good results. Six days before he died the temperature ran up to 103° at night, returning to normal in the morning. His leucocytes at this time numbered 8400 per cubic mm. and 85 per cent. were polymorphs. The next day his temperature rose to 103.8° and did not fall below 102° for the next two days. After this it came down to normal for 24 hours, when it again rose to 103° and subsequently to 97° on the following morning. During the last two days of life the temperature intermitted between 97° and 99.8°, at the time of death being 100°. The pulse varied from 54 to 120, becoming more rapid as the temperature rose. At no time was there any dyspnea. The pain in the abdomen persisted intensely till the time of death. It was in no way relieved by the taking of alkalies. Enemata generally evacuated a small amount of

fecal matter, but did not relieve the pain. Morphine in small quantities gave him considerable relief, and following its administration he generally had some sleep. During the last two weeks of his illness the blood pressure was extremely low, averaging about 85 mm. of mercury. During the last two days he had become extremely weak, but was comparatively clear in his mind to the end. There were no convulsions nor muscular twitchings nor rigidity nor any evidence of meningitis.

The autopsy was conducted six hours after death. The body was not emaciated. The pigmentation, particularly of his trunk, had faded considerably since death. The abdomen was slightly retracted. The peritoneum showed no special change. The intestines were not distended. There was no peritonitis and no free fluid in the abdomen. The appendix showed no gross abnormality. The spleen was acutely congested, slightly enlarged, soft, and on section, showed the Malpighian bodies very prominently. The liver was about normal in size, soft and slightly fatty. The gall bladder was not distended. It contained a viscid bile, but no stones. The kidneys were both slightly larger than normal. They were congested and showed a considerable degree of cloudy swelling. The urinary bladder showed no special change. The stomach was not dilated. Its mucous membrane was considerably congested, but in no region was there any ulceration. The intestines showed no special change. There were no peritoneal adhesions in any part of the abdomen, and in no place was there any ulceration of the mucous membrane of the intestine. The mesenteric glands were all slightly enlarged, so also were the lymphatic glands along the aorta. They were reddish on section and did not present any evidences of tuberculosis. The suprarenal capsules did not seem to be altered in shape and appeared about normal in size. They were, however, very firm. On section the entire suprarenal substance of both glands, as is found in the great majority of cases of Addison's disease, were replaced by a chronic fibroid and caseous tuberculous process. In no place could any adrenal tissue be found. It was remarkable how the contour of the glands had been preserved, and yet the tuberculous process had so completely replaced the gland substance. There was no other focus of tuberculosis in the abdomen which could be discovered. The lungs showed no special change. The heart was slightly reduced in size. The myocardium of the left ventricle was somewhat atrophied. There was no atheroma of the aorta. The thyroid was not enlarged. The thymus extended down over the front of the pericardium. It measured about two inches in length by one inch in breadth by one-half an inch in thickness. It seemed to be composed chiefly of lymphoid tissue and showed no evidences of tuberculosis.

This case presented the usual features of Addison's disease but was of special interest in several ways. The acute abdominal symptoms such as he presented are rather more common than are usually noted in cases of Addison's disease. Such symptoms seem specially to occur in the terminal stage of the disease. The recognition of such acute abdominal symptoms as this case presented, occurring in cases of Addison's disease, may prevent some unnecessary laparotomies. In this case also as is commonly found the thymus was considerably enlarged but whether this has any relation to the destruction of the suprarenals is uncertain. The suprarenals were both completely destroyed by tuberculosis without there being any other tuberculous focus in the body. The whole history of this case was comparatively acute. Till very close to the end the only complaint had been the change in color, nor had there been any great loss of strength or weight or any definite evidences of tuberculosis.

## ANGIONEUROTIC EDEMA.

By JACOB MUNTER LOBSENZ, M.D.,

NEW YORK.

The following is a report in detail of a case of this condition. This report may serve as a possible help in the determination of the etiology.

Angioneurotic edema, also known as Quincke's disease, is characterized by localized swellings of the skin and mucous membranes, appearing spontaneously, lasting from a few hours to three or four days. It is seldom fatal, but when it is, the lethal outcome is usually due to edema of the larynx. Studies of this condition by Milton, Graves, Quincke, Osler and others, show the following: (1) The cause is unknown, but nervous influences, autointoxication from the intestinal tract, intoxication from drugs, alcohol, heredity, and hysteria, have all been credited in various instances with bringing on the attacks. (2) The pathology is obscure, as the cause is not positively determined, and the condition is seldom fatal. It is more often referred to as a symptom-complex than as a disease. (3) A relationship to other diseases seems to have been established. This is especially true with reference to urticaria, and angioneurotic edema has been named "Giant Urticaria" by Milton. The following case is hereby reported: A professional man, aged 30 years, gave a negative family history. The patient was the only one in a family of eight children who had attacks of this disease. Personal history: Has had all the common diseases of childhood. Operated on for appendicitis some years ago. No rheumatism, diabetes or any other constitutional disease present. Is in excellent health, and always considered himself so. Has had psoriasis on elbows for five or six years. Habits regular. Does not drink alcohol in any form, does not use drugs, except salol occasionally as an intestinal disinfectant for attacks of urticaria. Is an excessive smoker of cigars. Bowels are regular, normal movement every morning. Appetite good, is not a big eater, but prefers fats and sweets, and diet is mostly made up of fatty and sweet foods. There is no trace of nervous element, and he is not hysterical.

Present history: For about two years he has had frequent attacks of edema of the face, but each attack was always preceded by urticaria. Urticarial attacks were very frequent, in fact, sometimes were constant. Every attack of urticaria, however, was not followed by edema. He could generally foretell an attack of edema, if he became constipated, or if he did not happen to move his bowels at the first call of nature, or when urticaria was more marked, as after eating an excessive amount of candy or fatty foods. Could cut attack of urticaria short and prevent the edema, if he took a mild cathartic and salol. The attacks of angioneurotic edema were not always of the same degree. The edema often manifested itself only in the larynx, or in the lips or in the eyelids. The

last attack was severe and typical enough to warrant detailed description.

He did not feel "right" in the bowels, although he had his accustomed bowel movement in the morning. He noticed some urticaria over the body during the day, and in the evening had another small soft bowel movement. Took about 30 grains of salol during the day. In the evening he noticed that one-half of the lower lip began to burn, and to swell quickly, and soon was swollen to an enormous size. He had a chilly feeling during the evening, and then a pronounced chill. He does not know if he had any temperature but felt as though he had. In an hour the lids of both eyes were swollen, and by the time he went to sleep, his lips and eyelids were enormously swollen. He took three grains of calomel, went to bed, but was up most of the night with severe colic and frequent watery movements. During the night he could feel a choking in the throat and he knew he was getting edema of the glottis. In the morning, the entire face was swollen, including the forehead. The penis was also swollen, so that micturition was painful. He had severe headache, and his face was unrecognizable. He took salts in the morning. For the whole day he had colic and diarrhea, which continued during the next night. The edema disappeared on the third day and was all gone on the fourth day. From the third day on he had marked urticaria over the whole body lasting for three days.

It would seem that this is a case of angioneurotic edema possibly caused by toxins arising from the gastrointestinal tract. This case also seems to confirm the alleged relationship between urticaria and angioneurotic edema.

233 West One Hundred and Twenty-second Street.

## A STUDY OF THE FLACCID SPINAL PARALYSIS WHICH ATTACKED LOUIS PASTEUR IN EARLY MATURITY AND ITS SIMILARITY TO AN ATTACK OF ACUTE EPIDEMIC POLIOMYELITIS.

### TOGETHER WITH A STUDY OF THE SILKWORM AS A POSSIBLE MEDIARY HOST OF THE SAME DISEASE.

By JACOLYN VAN VLIET MANNING, M.D.,

BROOKLYN, N. Y.

In a sympathetic sketch of Pasteur's life by Shipley[1] of Christ's College, Cambridge, I noted a comment on a paralytic attack which disabled Pasteur in his forty-sixth year. (Shipley: "Pearls and Parasites.") This hemiplegia, occurring in early life, struck me as very peculiar, the more so as I considered the revolutionary character of the work done by Pasteur in the years succeeding. That I came on this information in recreative reading while engaged in a research on poliomyelitis I must regard as a happy illustration of one of Pasteur's own epigrams: "In the fields of observation chance favors only the mind that is prepared."

The startling suggestion conveyed compelled me to look into the matter. I obtained that extended biography of Pasteur, which was written by Réné Vallery-Radot[2], a connection by marriage, during Pasteur's lifetime, and with his sanction. Pasteur, with the proud humility of the great, who feel that their work should speak for them, did not at once grant permission for the construction of his biography while living, and his consent was finally obtained by the plea, "Your presence in the flesh will be the guarantee of my exactitude." We may therefore consider these volumes to be authentic. I have also taken a few notes from the fine biography by Frankland.[3]

Pasteur, at this period, had not yet reached the zenith of his power. We may say that the preceding years of study of the formation of crystals, the fermentation of wine, the demonstration of the fallacy of spontaneous generation, and the research in which he was unwillingly engaged into the cause of the silkworm disease, constituted a mental discipline and apprenticeship to Knowledge. His revolutionary discoveries of the transmissible diseases of animals, anthrax, cholera, and rabies, and of toxins, their attenuation and use in immunization, all followed his convalescence from this hemiplegia so mysterious in origin and unique in manifestation.

This acute illness, followed by paralysis of the face, arm, and leg, occurred while Pasteur was engaged in the investigation of the silkworm diseases, pébrine, and flacherie. The testimony of all about Pasteur during his illness, including the bulletin of his medical attendant, indicates a flaccid and spastic spinal paralysis, initiated by an acute febrile onset, and accompanied by mental clarity and unbroken orientation for time and place. The faculty of the Académie de Médecine, already perplexed at these atypical manifestations accompanying a supposed attack of cerebral hemorrhage, received a communication from Pasteur embodying his latest discoveries, dictated by him from his bed in expectation of his own impending demise. In the following study it will be well to keep in mind that the subsequent mental work of the most revolutionary humanitarian discoveries, of the direction of a laboratory of young enthusiasts, and of preparing and delivering lecture courses at home and abroad was initiated and projected by a brain conjectured to have been the seat of a furious hemorrhage!

In the following account I have abstracted as nearly complete a clinical history of Pasteur's illness as could be obtained from the volumes mentioned. As the illness was diagnosed cerebral hemorrhage by celebrated consultants, it would not be amiss to review the characteristic manifestations of such an attack: "The shock or stroke of apoplexy is commonly sudden. The patient falls to the ground unconscious. . . . Such attacks may be rapidly fatal. In some cases there is a more gradual onset. The patient . . . gradually becomes unconscious." (Herrick.[4]) "The most frequent and prominent symptoms are sudden onset with loss of consciousness, convulsions, and coma, and if recovery result, hemiplegia on the side opposite the lesion. The onset may be very abrupt, the patient falling unconscious as though struck upon the head. If the attack comes on while the patient is standing, a weakness in one leg may cause him to fall or sit down, unconsciousness soon developing." (Musser.[5])

Louis Pasteur, the son of French peasants, was born at Dole in 1822. Married to a woman of excellent stock, they had in 1865, the year in which Pasteur began his investigation of the silkworm disease, a family consisting of one son and three daughters. Pasteur left for Alais, the center of the silkworm industry, in June, 1865; in September, 1865, his daughter Camille died of an acute illness, diagnosed typhoid fever. In 1866 Pasteur was again assigned to the study of the silkworm and

spent the summer at Alais with his family, but his daughter Cecile, twelve years of age, died in transit from a relapse of an acute illness, also diagnosed as typhoid fever. In January, 1867, Pasteur again took up his residence for the same study, in the same section of France, having with him his wife, his remaining daughter, and three students. During these years the family returned to Paris for the winter, but the spring of 1868 found them once more at Alais, where Pasteur found complete success and proof of all his rigorous prescriptions for the rearing of healthy silkworms. The infected worms which Pasteur studied so carefully presented at a certain stage a multitude of little black spots under the skin, which gave them an appearance of having been peppered, and so the malady was called the "pepper disease," or in the patois "pébrine." "If these spots of pébrine," said Pasteur, "were considered in conjunction with certain human maladies, in which spots and eruptions appear on the body, what interesting inductions might present themselves to minds prepared to receive them!" As Frankland does not fail to note, Pasteur, in studying the epidemic diseases of the silkworn, was first brought in contact with phenomena akin to those which obtain in infectious diseases of man, and acquired a great store of ideas which he afterward so successfully deployed into line in his brilliant attack on the subtile maladies whose study absorbed the later years of his life.

Pasteur returned to Paris early in October, 1868, and threw himself into his work, his classes at the Sorbonne, the organization of his laboratory, some further polemics on the silkworm disease, and projected experiments for the following year. This accumulation of mental work (is said to have) brought about extreme cerebral congestion.

On Monday, October 19, 1868, Pasteur, though suffering from a strange, tingling sensation of the left side, had a great desire to go and read to the Académie des Sciences a treatise by an Italian, who, having studied Pasteur's method and results, declared his the best methods of regenerating cultures of silkworms. On that day, in spite of an alarming shivering fit, which had caused him to lie down immediately after lunch, instead of working as usual, Pasteur insisted on going to the Académie at half past two. Mme. Pasteur, vaguely uneasy, accompanied him to the vestibule of the institute. Turning back, she met Balard, stopped him, and asked him to walk back with Pasteur, and not leave him before reaching his own door. Pasteur read the paper with his usual steady voice and walked back with Balard and St. Clair Deville. Pasteur dined very lightly and went to bed at nine o'clock. He had hardly got into bed when he felt himself attacked by the strange symptoms of the afternoon. Mme. Pasteur sent at once for Dr. Godélier, a friend and clinician, and Pasteur, paralyzed one moment and free again the next, pointed out to the doctor, without any faltering of voice, the progressive symptoms of the paralysis.

The cerebral hemorrhage (?) gradually brought about absence of movement along the entire left side. De Mussy and Andral were called in consultation. Somewhat disconcerted by the singular character of this attack of hemiplegia, Andral prescribed the application of sixteen leeches behind the ears. Blood flowed abundantly, and Godélier wrote in the next day's bulletin, "Speech clearer, intelligence perfect; some movement of the paralyzed limbs." Later the same day he wrote, "Complains of his paralyzed arm, 'It is like lead; if it only could be cut off,' groaned Pasteur." On Wednesday the written bulletin continues, "Mental faculties still absolutely intact. The cerebral lesion, whatever it may be, is no worse; there is an evident pause." Two hours later the words, "Mind active," were followed by the startling statement, "Would willingly talk science."

His recovery was regarded as hopeless. His friends hastened to his bedside. He said to De Ville, "I am sorry to die; I wanted to do much more for my country." A private letter from a cousin, Mme. Cribier, written October 26, gives a good idea of his condition at the close of the week: "The news is rather good this morning. He has been so restless all day that M. Godélier ordered silence in the whole flat. It is only in the study, which is farthest from the bedroom, and has padded doors, that we are allowed to talk. His mind seems so absolutely untouched and he is still so young. His stroke is accompanied by symptoms which are now occupying the attention of the whole Académie des Sciences. Paralysis always comes abruptly, whilst for M. Pasteur, it came in little successive fits, twenty or thirty, perhaps, and was only complete at the end of twenty-four hours, which completely disconcerted the doctors who watched him. It seems that this fact is observed for the first time, and is puzzling the whole faculty."

Pasteur's mind remained clear and luminous, dominating his prostrate body. "One night when I was alone with him," relates M. Gomez, "after endeavoring vainly to distract his thoughts, I gave up the attempt, and allowed him to express the ideas which were on his mind. Finding, to my surprise that they had his accustomed clearness and conciseness, I wrote what he dictated without altering a word, and the next day I brought to Dumas, who could hardly credit his senses, the memoranda which appeared in the report of the Académie on October 26, 1868, a week after the stroke which nearly killed him." It was an extremely ingenious method of ascertaining in advance whether the *graine* (seed, *i.e.* eggs) of the silkworm is disposed to flâcherie. November 30 Pasteur left his bed for the first time for an arm chair. Godélier's December bulletin ran: "General conditions most satisfactory. Progress evidenced daily by return of action in paralyzed muscles, inspires patient with great confidence. He is planning out his future serici-culture campaign, receives many callers without too much fatigue, and often dictates letters." December 15: "Walked from bed to arm chair with some assistance." December 29: "Walked a few steps without support." January 18, 1869, three months from his paralytic stroke, this indefatigable man traveled to Alais, lying on the cushions of a coupé, to observe the tests that were being made on forced silkworms. In February Pasteur slipped and fell on the stone floor of this laboratory, retarding his progress, but not sustaining any injury. He wrote to his old master, Dumas, during this month: "The improvement in the leg and arm seem to have begun again, but with excessive slowness. I am about to have recourse to electricity. In the morning I arrange the day's work. I get up at twelve, after having breakfast in bed, and the paper read to me. If fine, I then spend an hour or two in the little garden of this house. Usually I dictate to my dear wife a page of a little book I am preparing. About seven or half past I always feel terribly tired, and as if I could sleep twelve consecutive hours, but

I invariably wake at midnight. What makes me hope for an ultimate cure is that my appetite keeps good, and those short hours of sleep appear to be sufficient."

November, 1869, Pasteur, the state of his health being still very precarious, moved by short stages with his family to Villa Vicentina, at the request of Napoleon, to bring back the prosperity of former years to the silk culture on that estate. The non-profit bearing estate paid a net income of 22,000 francs the following year. In April, 1870, Pasteur published his "little book," which had grown into a "splendid" two-volume work, full of facts and documents on silk culture. In the preface he wrote: "Although I devoted nearly five consecutive years to the laborious experimental researches which *have affected my health* (the emphasis is not Pasteur's), I am glad that I undertook them." The Franco-Prussian war intervening, during which the laboratories of Paris were demolished in April, 1871, Pasteur wrote a friend: "The war has let my brain lie fallow. I am ready for fresh undertakings." Pasteur never recovered the full use of his limbs; his left hand having remained awkward, he entrusted the carrying out of his future experiments to his assistants, taking charge himself only of the note book in which all results were chronicled. In 1873, elected an associate of the Académie de Medicine, and attending its first meeting in April, "as he walked toward the desk allotted to him, his left leg dragging a little, no one among his colleagues suspected that this unassuming new member would become the greatest revolutionary ever known. (Vallery-Radot, Devonshire, Vol. II, Page 4.) Pasteur's faithful student, Roux, speaking of the period from 1876 to 1885, said: "Pasteur was always first on the spot. Every morning at eight o'clock I heard his hurried and slightly dragging footstep pass the window of the room I occupied at the extremity of the laboratory." Finally there is one brief statement that this paralysis was spastic as well as flaccid in a letter written by an intimate friend in 1889: "Pasteur is short. Since 1870 his left arm and leg, smitten by apoplexy, are somewhat stiff, and he drags one foot much like a wounded veteran. Weary, traversed with deep furrows, the broad forehead wrinkled, the mouth slightly drawn by paralysis, the living thought still flashes beneath the deep brow." On November 1, 1894, Pasteur was seized with a violent attack of uremia, was in coma for four hours, and was not left alone day or night until Christmas day. He recovered from this illness, and in May refused the Order of Merit from the German Emperor. That May he spent the afternoons in a little tent under the chestnuts in the garden of the Pasteur Institute, and the rest of the summer was spent under the pines and purple beeches of Villeneuve. His strength diminished day by day. He witnessed the ruin of what in him was perishable, but his eyes remained bright and clear. In September he could not leave his bed. On September 28, 1895, very peacefully he passed away. In the interval of twenty-seven years which existed between an attack of supposed cerebral hemorrhage and his death, Pasteur plunged into an entirely new sphere of research, in which he won his most glorious laurels, and had to fight his fiercest battles!

Wickman states that the clinical picture of encephalitis, or the cerebral form of poliomyelitis, is a regular spastic hemiplegia, and that it may be known from hemorrhage and other disease, in that the condition is acute, febrile, and has constant prodromal symptoms. It is to be noted that while the onset of cerebral hemorrhage is usually abrupt, this attack of Pasteur's began with a distinct aura (Manning[6]), and with the prolonged chill which usually initiates an acute infectious disease. Cerebral hemorrhage is accompanied by a profound coma; Pasteur exhibited mental exaltation, elucidating and dictating a technical and ingenious method for the discovery of the presence of infection in the eggs of the silkworm! The symptom of severe pain is not present in the stertorous coma of cerebral hemiplegia; Pasteur, on the contrary, suffered such agonizing pain in the arm later paralyzed, that he expressed a wish that it might be cut off!

Before further analysis of Pasteur's case I would like to present a case of acute epidemic poliomyelitis, presenting only one chief difference from Pasteur, in that the victim was a somewhat younger male. This naive history is taken from a personal letter to the writer received after the publication of an article on the subject in a popular magazine (Manning[7]). It will be noted that while Pasteur's attack was said to be due to extreme cerebral congestion, this young man, an electrician of the twentieth century, was told his attack was brought on by the constant testing of hot wires with his hands.

Portion of letter from E. L. N., to the author:

"March 4, 1911.

"My age is twenty-six. September 29, 1910, I was taken with what felt like growing pains in the calves of my legs, which kept me awake all night, and the next morning I could walk with difficulty. About 10 A.M. I could not walk at all, and was taken to the hospital about noon. I felt fine, was carried to a cab, and enjoyed a cigarette while going to the hospital. Never felt better in my life, but first night at the hospital I had a temperature of 101°. This happened at South Bend, Indiana. I had lived there eighteen months, and was temporarily superintendent electric construction. There were no cases in South Bend until mine, where the doctors seemed at a loss to know what I had, for I could not move my limbs, yet had acute feeling as to hot or cold, dull or sharp tests. I seemed a freak, for while in the hospital I had eight doctors examine me for their own pleasure. I had no headache, no neckache, no backache. The fourth day at the hospital my back became stiff, and I could not sit up, so was shipped home on a stretcher. . . . I have slept well, and eaten well. . . . By Christmas I could sit up, and my left leg was nearly normal as to movement, the right I could move but little. . . . I am now up and around on crutches. . . . I cannot life my right leg as one would in climbing stairs, yet the knee is free. I cannot keep my balance, although it seems to be getting better. My case seems so different to many cases that I have read and heard of that I thought I would write you, and if you can spare the time I would like to have your ideas of my case."

The following letter, which came in the course of a routine investigation of the writer the preceding fall, showed that poliomyelitis was in the state at the time of this young man's attack:

"State Board of Health, Indianapolis,

"October 13, 1910.

"We regret that we cannot give you any information regarding poliomyelitis in Indiana. . . . The disease is practically a new one, and we know

it is occurring in various parts of the State, but is not being recognized. . . . Regretting that we cannot be more helpful and specific, etc."

I have chosen this case rather than one of an older man with an attack of frank poliomyelitis terminating in hemiplegia to compare with Pasteur's case, for the reason that this young man, like Pasteur, exhibited a degree of mental exaltation which never has been and never will be an uninterrupted accompaniment of cerebral hemorrhage.

I do not infer that it is a constant accompaniment of an attack of poliomyelitis, but this letter is evident that a vigorous male, suffering from the purely spinal form of poliomyelitis, may experience an undoubted cerebral excitation. Males are more susceptible to the infection of poliomyelitis than females, and in all recent epidemics cases have occurred in men from 40 to 73 years of age. Such a case, which was one of forty occurring from April to September, 1910, at Mason City, Iowa, was reported as follows: Case I. C. T., male, aged 48; laborer; was taken sick June 24, with a chill, fever, pains in the legs and back, stiffness of neck, and some delirium. On the third day there was paralysis of both thighs and legs, and both upper arms and forearms. When last seen, November 24, 1910, the lower limbs and upper arms were still paralyzed, flaccid, and atropic, but showing some improvement. This is a typical case of acute anterior poliomyelitis. (Anderson and Frost: Abortive Cases of Poliomyelitis, *Journal of the American Medical Association*, March 4, 1911.) With the exception of the slight delirium, accompanying a more extended paralytic invasion in the working man, the clinical manifestations are identical with those of Pasteur's case, and their ages also closely correspond.

In this particular it is also notable that of eleven of the cases used in the study of Anderson and Frost just quoted, six were adult males, as follows: Case 1, male, 48 years, laborer; case 4, male, 34 years, physician; case 5, male, 30 years, merchant; case 6, male, 45 years, farmer; case 9, male, 49 years, farmer; case 10, male, 48 years, carpenter. All except case 1 were considered arrested forms of poliomyelitis occurring in close association with frank forms of the disease.

We have now outlined the vivid facts in Pasteur's illness which suggest an analogy to, or, in fine, the identity with an attack of acute epidemic poliomyelitis, which we will summarize briefly: I. Possible presence of epidemic disease: June, 1865, Pasteur engages in research of epidemic silkworm disease; September, 1865, death of daughter Camille from acute infection; May, 1866, death of daughter Cecile from acute infection; October, 1868, Pasteur prostrated with an acute attack of illness. II. Symptoms of Pasteur's attack which indicate presence of poliomyelitis: Auro, hyperesthesias, and motor weakness; acute onset, severe, prolonged chill, fever; total remission of attack for six hours; peripheral neuritis, an agonizing pain in left arm; coma, none; mental exhilaration, marked; spinal paralysis, progressive and regressive in character; sequelæ, the typical flaccid paralysis and drop foot of poliomyelitis, with involvement of facial.

As this study was not undertaken as an interesting bibelot, but in the strong hope that it might throw some light on a possible unknown host of the organism of poliomyelitis, so favorable to its existence that it might be demonstrated in a greater than ultramicroscopic form, much has been omitted of interest, and pertinent to the subject, which can be reasoned out from the clinical history given.

THE SILKWORM A POSSIBLE HOST OF POLIOMYELITIS.

I will present evidence which indicates that the silkworm may act as host to the organism of poliomyelitis, in the strong hope that its presence may be demonstrated in the pregenerative moth stage of the insect, as a greater than ultramiscroscopic germ.

Poliomyelitis has been endemic in North Europe for a long period. It is known to have been epidemic in the Luxembourg, France, since the eighth century. (Manning[8]). Its epidemiological peculiarity of increasing rapidly during the height of summer, when insect life is at its apogee, would indicate its probable transmission by a blood-sucking insect. The insect is yet unidentified, and its identification is hampered by the fact that the organism of poliomyelitis when taken from a human host remains ultramicroscopic in size, and cannot therefore be seen, although it may be reproduced in vitro. Dr. Philip Shepherd of Massachusetts considers the biting fly, or stable fly, as the insect agent of transmission of poliomyelitis. The writer has published a study of the bedbug as the probable agent of transmission. (Manning.[9]) Dr. Howard, chief of the Entomological Bureau, in a personal letter to the writer said: "I believe that in these cases of the transmission of disease by insect, especially when the insect may be a necessary secondary host, we must look first at those insects which are practically domesticated, since the development of such a relation involves more or less intimate association for many generations."

Verjbitski's[10] remarkable series of experiments which demonstrated the transmission of plague by both bedbug and flea was comparatively simple in technique, for the plague bacillus is a fat and lusty germ. The ultramicroscopic germ of poliomyelitis, as has been said, while cultivated *in vitro*, has never been seen. It occurred to the writer that the silkworm, which increases to fifteen thousand times its own weight during its first month's existence in the worm stage, might present a culture media of such high nutritive value that an organism ultramicroscopic in other media might here take on microscopic size. It is therefore not a possible agent in the transmission of poliomyelitis which is to be considered in this article, but an enhancing intermediary insect host, with a possible accidental infection of man. The silkworm has been a domesticated member of French households for many generations, the peasant grower housing the worm in his own domicile. In 1700 France produced annually 6,000,000 kilograms of cocoons. Louis Philippe increased the industry to 20,000,000 kilograms, totaling 100,000,000 francs. The name of the tree of gold was given to the mulberry tree, and the industry became a vocation in Italy and other Mediterranean countries. Suddenly all these riches fell away. A mysterious disease was destroying the nurseries. "Eggs, worms, chrysalids, moths, the disease may manifest itself in all the organs," wrote Dumas, when advising the senate to appoint the young chemist, Pasteur, to investigate the cause of the disorder. The epidemic disease was at that time so extended that pure seed, *i.e.* eggs of the silkworm, could be obtained only from far-away Japan. This disease was already called corpuscle disease, because some observer had found shining

oval bodies in the dead moths. The Italians called this disease of the silkworms "gattine," from the Italian diminutive *gattino,* kitten, for the sick worms held up their heads and put out their hooked feet like cats about to scratch. The most common name, however, was pébrine, from the peasant patois, *pébré,* pepper, for the sick worms became covered with a multitude of little spots which the peasants said looked as if they had been peppered. These minute spots appeared under the skin on the heads of the worms, and on the rings of their bodies.

These three names of the silkworm disease in common use are replete with suggestion and information; they first tell us that this disease is due to some microorganism; the second name is assurance that the onset of the illness was accompanied by convulsive and spastic conditions, from which we deduce an irritation of their nervous and muscular mechanism; the spots which came under the skin where they had not before shown indicate a cutaneous exanthem of an inflammatory or purpuric character. "If these spots of pébrine," said Pasteur, "were considered in conjunction with certain human maladies in which spots and eruptions appear on the body, what interesting inductions might present themselves to minds prepared to receive them!" We will note here that the exanthem of poliomyelitis is fairly constant, and has proved one of the most misleading symptoms of the disease, being often mistaken for measles. Pasteur found that if the diseased chrysalis became a moth the moth had deformed antennæ and withered legs, and the wings seemed singed; most usually the worms died during the feeding stage, or on the frames in the interim before spinning began. The atrophy of the affected muscles in poliomyelitis is recalled by the withering and deformity of the diseased moths.

The microscopic corpuscles had been seen in the diseased silkworms by Guérin in 1849; their pathological import had been suspected by Cornalia; their abundant presence in all diseased larvæ and moths had been observed by Frey; Osima of Padua had even found them in the eggs; Vittadini in 1859 had suggested that these eggs be examined microscopically to ensure that only healthy ones be preserved (Frankland). Breeders of silkworms saved a sufficient number of eggs from one year to the next to ensure a full crop of cocoons. Pasteur was able to show that the infected worms were invaded by masses of these oval luminous bodies. He studied the insect on its emergence from the egg, through the feeding stage with its successive moultings, and enormous growth, watched the "precious insect when, its body full of liquid silk, it is hastily mounting to placed twigs, there to construct its golden prison," removed chrysalids from their cocoons for examination, and observed the mating of the recently emerged moths, and the female's ovulation. Pasteur was able to demonstrate the presence of the microscopical corpuscles at every stage of the development of worms taken from infected nurseries, by triturating the insect with water and examining it with a high-power lens. His method of prophylaxis is beautiful in its simplicity and effectiveness. The female, after ovipositing, is preserved with her eggs in a small square of linen. Each female is examined for corpuscles, and if infected she and her eggs are burned. Only those eggs are preserved which come from a non-infected mother. Pasteur worked out this method after much observation, and many experiments, and for two years he was misled by circumstances which have a certain interest in the present study Pasteur found in an infected nursery that the frames often presented a wide difference in appearance; the worms on some of the frames were of so healthy an aspect that the breeder confidently expected from them a large percentage of cocoons and good breeding stock, while other frames would present worms manifestly ill and drying rapidly. Pasteur found these dying worms presented few or no corpuscles, while the worms on the better appearing frames, when they went into the chrysalis stage, were found to present masses of germs, developing more steadily day by day. It was two years before Pasteur revised his belief that the corpuscles were the result of the disease and reached the correct conclusion that the disease is caused by the corpuscles. The bearing of the non-appearance of the corpuscles in the dying worms on our present study becomes evident when we consider that in the research for the causative factor of poliomyelitis, while a constant minority of investigators have reported the presence of germs in the blood of human victims during the acute stage (Dixon of Pennsylvania), the majority of investigators have been unable to demonstrate visually the presence of germ or spore. There may exist then a possibility that the germ of poliomyelitis, under exceptionally favorable conditions, and during a stage preceding the onset of the disease, may be present in the organism, to rapidly disappear during the reactionary period which we term the febrile stage, or remain secluded in spore form in some remote and unsuspected area of the economy.

Pasteur further proved that the worms could become infected with this disease in two ways: (1) By direct contact, the infected worms crawling over the healthy and puncturing them with their hooked feet. (2) Indirectly, by soiling the mulberry leaves on which they feed with the very infectious excreta. He also demonstrated that the corpuscles developed chiefly in the chrysalids on the eve of reproduction. We may here bear in mind that while the association of poliomyelitis with the period of dentition of childhood has been so notable as to develop the two common names of the disease, teething palsy and infantile paralysis, we are only now becoming aware of the percentage of adolescent males, and it may be of pregnant women and unborn children attacked. The periods of dentition, of adolescence in the male, and of quickening in the female are the periods of high tide in the nutritional development of man.

The silkworm increases to 15,000 times its own weight during the first month of its existence (Vallery-Radot, Vol. I, p. 205). It is during this time of extraordinary increase in nutrition and soft flux that it becomes most subject to the attack of pébrine. Is it therefore possible that an organism which in the slowly developing human being rarely if ever attains to more than ultramicroscopic size, might in such culture media take on microscopic size?

Before summarizing, it must be noted that the summer of 1908, which preceded the spinal paralysis, Pasteur announced there were two diseases of the silkworm. Flacherie, or morts flats, was so-called because the worm, sickening of this disease in the fourth molt, turned black and was found dead and empty with the contents of the body cavity consumed away. Pasteur considered this a disease of the digestive system due to vibriones and contagious. He elsewhere speaks of the germs of flacherie as bacilli, and also of spores of these germs, similar in appearance to the corpuscles of pébrine. In Oc-

tober, 1868, Pasteur, fresh from the study of these germs whose contagiosity he had demonstrated, was after an acute febrile onset, prostrated by an attack of flaccid spinal paralysis, progressive and regressive in character.

Drawing an analogy between the reactions of a transmissible disease as it affects the human race, and any given insect, is a delicate matter, for it treats of an almost unknown subject. If, however, we can establish that a domesticated insect which was of healthy stock at the time of its introduction into the human dwelling, became after many generations and decades of years the subject of an epidemic disease; if we can ascertain that certain signs and symptoms are constant accompaniments of the epidemic when it attacks these insects; if not dissimilar signs and symptoms are the constant accompaniment of an epidemic disease known to attack the residents of the same territory; if a scientist while engaged in the investigation of the one epidemic, is taken acutely ill with symptoms suggestive of both diseases, we are warranted to make a close and particular study, which will prove or disprove such relationship.*

*This study was submitted to the criticism of Dr. Mazyck Ravenel, Director of the Hygienic Laboratory of Wisconsin University, and a student at the Pasteur Institute in 1894. Dr. Ravenel informs me that an impression existed that the illness at midlife had been occasioned by a specific infection. A review of the carefully recorded symptomatology demonstrates that the symptoms do not accord with those of hemorrhage from an atheromatous artery nor of cerebral gumma, thus disposing of an unfounded imputation. The study was completed in March, 1912. In September, 1912, the successful transmission of epidemic poliomyelitis by the biting stable fly, *Stomoxys calcitrans*, was announced by Drs. Rosanau, Anderson, and Frost. Subsequently the germ of poliomyelitis was cultivated and demonstrated by Noguchi.

## A PLEA FOR EARLY LAPAROTOMY IN ABDOMINAL DISEASES.

By ALEXANDER GOLDMAN, M.D.,

NEW YORK.

PHYSICIAN TO THE BRONX HOSPITAL AND DISPENSARY.

With the present advance of science the general practitioner is put into the position of a skilled workingman, who is a part of a whole system of man and machinery, used to produce a certain article. No one expects, with the present state of division of labor, a single person to complete an instrument, for instance; while it is true that the skilled mechanic will understand well all the parts and know how they are produced, he will not make the article by himself. The same is true of the internist of today. He must recur to the laboratory man, the *x*-ray man, and the surgeon, not only to treat but also to make a proper diagnosis. The physician may be an expert in his line, but where there is a question of the life of his patient, he becomes a man with feeling and sympathy for his brother man and will not decide one way or the other unless he has the opinion of someone else who may have more experience on that subject or may have had success in such cases before. We hesitate little in getting the opinion of our friend, the internist; we rush very often to the laboratory man, or *x*-ray specialist, but somehow we hesitate to call the surgeon in—at least we call him in very often as the last resort, and what is more, we seldom take his opinion as final.

The patient nowadays understands as well as the physician the development, the science and art of medicine are undergoing and will very often demand the opinion of specialists on his case—and he, as well as the physician, is reluctant to take the opinion of the surgeon as final.

It is on the importance of the surgeon's opinion and interference in medical cases that I want to speak in this paper.

The part of medicine where the surgeon's opinion and interference is of the greatest value and importance to the patient as well as the physician is the one treating abdominal diseases, and that at an early stage, for when a diagnosis can be made without the surgeon the case is either acute or such that interference is of no use. I do not mean to say that the medical man cannot or does not make the diagnosis—what I mean is that the medical man waits for too many positive signs before he calls in the surgeon. Who of us has not examined a patient coming to the office and as a result of this examination have found the conclusion that someone has missed a chance of an early diagnosis and that the patient is past all help.

We know well that the physician, as well as the layman, feels that the surgeon uses the knife only too often. But putting all economic reasons aside, what is better tactics; to remove a healthy appendix through a mistaken diagnosis or treat a man medically for an ulcer of the stomach until it has become an incurable cancer? I shall leave it to you to judge.

With the present stage of surgical knowledge—technique and asepsis—it becomes a question what is more safe for the patient—a laparotomy by an expert, even if it is for diagnosis only, or the continuance of treatment with drugs and losing valuable time by the internist.

Taking up abdominal conditions that give us most trouble as to diagnosis we find that very often a gallstone colic will simulate a gastric ulcer, also acute appendicitis; appendicitis will often make us think of some tubal condition. Have we not seen cases of chronic appendicitis diagnosed as prolapsed kidney, etc.? All these diagnoses may be made by very good men and why should the patient not get the benefit of the doubt and have the surgeon decide the question and thereby save or prolong life or make life less miserable?

I have before me a few cases that I want to describe to you to illustrate my contention. Before doing that, however, I want to quote a few authorities on the subject of surgical interference in medical cases.

First, I shall state that the danger of laparotomy in clean cases is the danger of anesthesia only, that the mortality of lapartoomy per se is nil. This statement is based on statistics obtained by Dr. John

C. A. Gerster in Mt. Sinai Hospital and also on the experience of the Mayo Brothers. Gaston Lyon, in his "Diagnosis and Treatment of Stomach Diseases," on page 376, says: "If one does not wait until the last stages to operate on a patient suffering from pyloric stenosis, the chances for non-success are nil in the hands of an able surgeon." Also, if it is true that perchance in rare cases the death of a cancerous patient has been hastened by intervention, many have been saved by early surgical interference who would surely have died if not operated upon, and we must consider the surgical treatment of pyloric stenosis as one of the greatest conquests of surgery.

On page 578, the same author says: "Laparotomy is a means both of diagnosis and treatment in certain stomach conditions. An exploratory laparotomy is justifiable in all cases where the patient presents symptoms that do not respond to medical treatment, like vomiting, pain becoming more and more severe; when one can rule out a nervous state, or when one is justified in thinking of a physical obstruction." On page 380, quoting statistics, Lyon finds that in ninety-three cases operated on the earliest recurrence was after three years.

Van Hacker gives a case of six years and Czerny, Löbker, and Franck have cases of seven years post-operative freedom from recurrence. One of the most important points the author insists upon is an earliest possible diagnosis, for in the early stage of cancer we find both a small and movable tumor and a patient in general good condition.

As to results of gastroenterostomy the statistics show a reduction of mortality from 20 to 30 per cent. to 5 and 8 per cent. at the present day. The general improvements are such that the vomiting ceases, weight is gained, appetite is improved, and generally the patient gets a temporary new lease of life.

Pirilla in the *Archiv für Verdauungs Krankheiten*, Bd. 18, page 294, reports from the medical department of the University of Helsingford a series of 120 cases of ulcers of the stomach; of those that were medically treated 30 per cent. died of their ulcers and sequelæ; 28 per cent. of these cases died within one or two years after discharge from hospital.

Speaking of gallstones, Kelly, writing in Osler's "Modern Medicine," states that "The risk of gallstone operations is the risk of delay—since with delay serious infections of the biliary tract supervene. . . . The operation is indicated in those cases in which with reasonable certainty the presence of pericholecystic, perigastric, or periduodenal adhesions may be surmised. The fact that the operative results are not what they were hoped for is not in itself a contraindication to operation; on the contrary, these untoward results are often attributable rather to the fact that in many long delayed cases the anatomical lesions are such as to be almost if not quite irremediable by any and all means at our command."

In the same work he states: "Even the suspicion of malignant disease is an indication for an operation, the hazard of the operation is less than the risks attendant upon delay . . . the operative treatment of cholelithiasis naturally tends to reduce the incidence of carcinoma of the gall-bladder; this in itself is a prophylactic measure."

Of the value of lost time in acute and subacute and even chronic appendicitis I shall not speak, as this is a subject with which every practitioner is only too well acquainted.

The cases I want to quote are the following:

Case I.—Baby Berman, nine months old. Suddenly started to vomit and family called me to see the child two hours later. When seen the child looked sick; vomited after taking the slightest amount of water. Bowels had not moved since the previous day. An enema was given and same returned forcibly, consisting of clear water. No masses felt. Slight resistance of abdominal wall. Diagnosis of intussusception was made and child transferred to Lebanon Hospital. Dr. Kakel operated on it at once and a mass was found in right hypochondriac region consisting of ascending colon and cecum. Child made an uneventful recovery and is five and one-half years old today.

Case II.—Baby L., 18 months old, bottle baby. Mother suffered from convulsions previous to and during pregnancy. The baby suddenly started to vomit in the morning and felt bad. When I saw it, the child gave no physical signs. Toward evening mother reported baby well. An hour later child began to vomit a fluid of a brownish color and fecal odor. It was taken to Mt. Sinai Hospital and operated on at one o'clock in the morning by Dr. Moschcowitz. The intestines were found collapsed. The child continued vomiting after the operation until the next day, when it died. Diagnosis: intussusception; late operation.

Case III.—Baby F., 15 months old, suddenly vomited; had been constipated. Mother gave an enema, some bloody fluid returned. I saw the child a couple of hours later; it looked sick; abdomen was distended; no masses were felt; there was slight protrusion of rectum through anus. Diagnosis: intussusception. Taken at once to Mt. Sinai Hospital, operated on a few hours later by Dr. A. A. Berg. The mass was found and reduced. The child is well today.

Case IV.—Mrs. M., 35 years old. Has had three children. For the last few years has been suffering pain in the abdomen—first in the lower part, but when the patient was seen it was sometimes at McBurney's point and sometimes in the region of the gall-bladder. She had lost weight and felt so bad that she made up her mind to be operated on, though she did not know for what. Has been treated medically for several conditions for the last few years by different physicians. Her life was a burden to herself and to her whole family for the last three years. Was admitted to St. Luke's Hospital—operated on by Dr. Lyle. An incision was made over the appendix, and this part was found chronically inflamed with adhesions spreading up to the gall-bladder. Another incision was made over the gall-bladder which was found full of stones—over one hundred being taken out. So many adhesions were found over the whole right side that one wondered she had lasted so long. She made a perfect recovery.

Case V.—Mr. M., musician, 35 years old, has been treated medically for hyperacidity and then for ulcer of stomach for the last five years. Lately he became very sick and a diagnosis of gallstones was made. Condition became so severe that he made up his mind to be operated on. Dr. A. A. Berg operated on him at Mt. Sinai Hospital. An ulcer of stomach was found with very extensive adhesions to the surrounding viscera. The adhesions could not be removed so a gastroenterostomy was performed. The patient made a good recovery, and regards himself now as perfectly well.

Case VI.—L. C., 35 years old. For the last seven years suffered abdominal pain. Diagnoses of gallstones, floating kidney, hyperacidity, and pyloric ulcer were made by different responsible physicians. At last he became so ill that he demanded an operation. Dr. A. A. Berg operated and found a pyloric ulcer. This was excised, and a gastroenterostomy with temporary occlusion of the pylorus was performed. Patient recovered, gained health and weight. On and off he suffers from indigestion, due to errors in diet, but otherwise feels well.

Case VII.—Mrs. X., a woman of sixty, began to have pains in the right hypochondriac region, vomiting and getting weaker all the time. Diagnosis of inflamed bowel was made. She was put to bed and treated medically. Lost weight and strength during the two or three months that she was treated by three different physicians. At last she was told she was well enough to go to the country to recuperate. When I saw her she had pain over the gall-bladder, in which region resistance was made out and a mass felt. She went to hospital for operation on gallstones. Dr. A. A. Berg confirmed the diagnosis but refused to operate as the patient was too much exhausted. Two days later she suddenly expired.

Case VIII.—Mrs. G., sixty-five years old, three years sick on and off with pain over gall-bladder region. Has been treated by her family physician and was told she had indigestion. Was seen by several physicians and no operations were suggested at any time. When patient was seen by me the first time a few months ago, a large mass was felt over the gall-bladder. Abdomen distended and contained some free fluid. When the patient was seen a month later the abdomen was full of fluid, there was edema of the extremities, and the patient was in a dying condition, her disease being inoperable.

Case of Baby Berman, early diagnosis, early operation, good results. Symptoms were not classical, but then who would wait for them. Patient was given the benefit of the doubt and recovery perfect.

Case of Baby L., loss of time for sufficient symptoms—parents did not think child sick enough for physician to call again and by that time the shock was sufficient to kill the baby.

Child F., early diagnosis, early operation, good result.

Mrs. M., wasted several years in misery, no positive diagnosis could be made, every physician who treated her saw different symptoms, and no surgical interference was advised. Luckily she took matters into her own hands, decided for herself and thereby saved her own life. It is hard to tell whether she suffered originally from an acute appendicitis, or from gallstones and associated inflamed gall-bladder causing adhesions to extend down to the appendix. However, it is very hard to say how far or near she was to lose her life under the medical treatment she underwent for the few years of her suffering.

Mr. M. What will happen to the tumor or mass of adhesions that Mr. M. has stored away around his pylorus—time alone will tell—but if it speak in the language it usually does in those cases—medical treatment will get another victim sacrificed to its persistence in doing things blindly as they ought not to be done.

Mr. C. well illustrates a case that has been saved at the stage where Mr. M. should have been gotten at. His ulcer is out and if he behaves, we know he will be a well man. We are more sure of him, though he suffers from occasional indigestion due to indiscretion in diet, than we are of Mr. M., who feels well today—a year after operation.

Why Mrs. X. should have been kept in bed for several months and reduced to a stage of absolute exhaustion, I cannot tell. When seen first by one or two of her physicians, the family was told distinctly that she was not very sick and that a little rest would bring her around very quickly. No surgical interference was advised, though the family wanted to know whether there was anything to operate on.

Mrs. G. represents the usual picture every physician sees on and off. At the beginning of the game, when something could have been done, the patient was treated with our good grandmother's mixture of rhubarb and soda—and when symptoms became classical of carcinoma, the woman was condemned to death in a classical manner.

I want to add that the different physicians treating the different cases described here were all able men and fully competent to make a proper diagnosis, and the different diagnoses made at different times on the same patient were fully justifiable, but what I contend is that just for these reasons, the fact that these patients were not giving definite data for one positive diagnosis, they were entitled to the benefit of the doubt and should most of them have been turned over in proper time to the surgeon for a laparotomy, if only to clinch the diagnosis and thereby prolong or save life.

1446 Prospect Avenue.

## VENEREAL DISEASES IN THE NEGRO, WITH SPECIAL REFERENCE TO GONORRHEA.*

By JOHN O. RUSH, B. Sc., Ph. G., M. D.,

MOBILE, ALA.

ASSOCIATE PROFESSOR GENITO-URINARY DISEASES AND SYPHILIS, SCHOOL OF MEDICINE, UNIVERSITY OF ALABAMA; CHIEF GENITO-URINARY SURGEON, UNIVERSITY DISPENSARY; ATTENDING GENITO-URINARY SURGEON, CITY HOSPITAL.

This subject is no new one, but it has been brought to my special notice by Dr. Wm. A. Steel, of Philadelphia, Pa., who, on December 27, 1912, wrote me a circular letter concerning an article in the edition of September 21, 1912, of the Medical Record, by Dr. J. Madison Taylor. Dr. Steel, in his letter says: "The article of Dr. Taylor has excited a degree of unfavorable criticism from different sources, who contend that the imputation is not fair to the negro race." He closes his letter with the following questions:

"In your practice, as compared to the white race: (1) Is gonorrheal urethritis more prevalent among the adult male negro? (2) Are its sequelæ, pyosalpinx, pelvic abscess, etc., more common among the adult female negro population? (3) Is the proportion of gonorrheal ophthalmia greater among the negro newborn? (4) Is the disease more prevalent among the city or country population? (5) Is the disease as virulent in the colored population? (6) Is chronic gonorrhea, and its sequelæ, prostatitis and seminal vesiculitis, more prevalent in the negro male? (7) Are these conditions responsible for sexual lawlessness mentioned in questions stated in Dr. Taylor's article?"

I had not read Dr. Taylor's article until after I had received Dr. Steel's letter, since which time I have read and re-read it several times, and there is not one thing apparently unfair or unjust to the negro race contained therein. The article is true from beginning to end, and one has only to read it partly through to be convinced that Dr. Taylor is not theorizing, but is discussing a subject plainly and fairly, as only one who is thoroughly conversant with a subject can. He gives credit where it is due, and speaks in plain terms of the weaknesses and the deficiencies of the negro as a race. And from my personal knowledge of the negro, and his habits, and his mode of living, I must say Dr. Taylor is liberal.

For the past seven years I have been in charge of the department of genitourinary diseases and syphilis of the Dispensary School of Medicine of the University of Alabama, acting assistant surgeon U. S. Marine Hospital, attending genitourinary surgeon City Hospital, during which time I have treated 7,000 negro men, and I have never questioned more than a very few and received a negative answer as to his having had gonorrhea. The pitiable part of it is they do not consider gonorrhea a disease, but "just an overstrain," to which they pay little or no attention so long as there are no attendant complications. The average negro male believes all necessary to cure "a little thing like the

*Read before Mobile County Medical Society, Mobile, Alabama, February 22, 1913.

clap" is to take a small pill made from the resin of the pine tree, or ten drops of turpentine on a piece of sugar, three times a day, or inject into the urethra pure spirit of turpentine. And the majority of them believe firmly that the quickest, surest way to cure it is by excessive sexual intercourse, or if they can have sexual intercourse one time with a virgin they will be cured of any and all venereal diseases. I have had them tell me this often. I should like to lay stress on this "method of cure." It is not infrequent that I have little negro girls, ranging in ages from seven to twelve years, brought to me for treatment for syphilis, chancroids, or gonorrhea, the victims of this belief. Last year a negro woman, aged thirty-two, and married, was referred to me for treatment. Upon examination it was found that she was suffering from multiple chancroids and gonorrhea. The next day she returned, bringing her five-year-old boy, who, upon examination, was found to have gonorrhea, a large chancroid underneath the prepuce, and a suppurating bubo in his left inguinal region. Suspecting the source of his infection, I questioned the mother privately, and she told me she had "always heard that if a person had any disease of the privates, they would be cured if they had intercourse with someone who had never had intercourse before." So she made use of this little boy, but said, in extenuation, "I didn't know I could give any disease to him. I thought it would cure me. I thought little children couldn't have such diseases." This particular case, in which all of the revolting details may be scoffed at as being unusual among negroes, is cited as one instance out of many as confirming my argument that negroes of the South, male and female, resort to revolting practices, founded on honest belief, to rid themselves of venereal diseases.

I have had a number of such cases on my service during the time I have been on service at the University Dispensary.

At present we have thirteen negro male patients in the Marine Hospital, ranging in age from nineteen to sixty-five years, and all of them admit having had gonorrhea; several say they have had it nine or ten times, but don't consider that anything. One man said to me to-day, "Why, Doctor, I don't mind having the clap; it don't bother me, and all I do for it is just get me a woman and stay with her until it stops running." All of them give histories of suffering from prostatic inflammation, and several of them have been patients of mine for acute gonorrheal epididymitis, several I have operated upon for urethral stricture (external urethrotomy).

In one ward of our City Hospital there are at present twelve negro male patients, and of this number all twelve have had one or more attacks of gonorrhea, and some of them are there now for treatment for some of the complications of gonorrhea. During the year 1911 we treated in the genitourinary dispensary at the University 1,960 men; of this number 1,900 were negroes, and of the 1,900 all gave histories of having had one or more attacks of gonorrhea, and the majority of them had been patients there in previous years for the same disease. During 1912 we treated 2,500 patients in the same department. Of this number 2,300 were negroes and 2,100 gave histories of having had one or more attacks of gonorrhea, or were then there for treatment for their first attack.

It is a rare exception to find a negro who will take treatment for gonorrhea for a longer period than one week, and most of them give it up even in a shorter time. We are striving daily to teach them the necessity of medical attention in such cases and the importance of a cure. Our dispensary is rapidly growing, and we see an increase in the number of times patients come for attention. Our present trouble is to convince them of the necessity of refraining from sexual intercourse while the disease is active, and to show them the havoc wrought by men who do not do so—but my words of advice and warning go in one ear and out the other. For instance, a few days ago, a young negro presented himself for treatment with a virulent attack of gonorrhea, of five weeks duration. He asked me, "How long before I can 'do business' again?" And I told him possibly two months, if he took treatment properly. He laughed and said, "Now, looker here, Doctor, you're jokin'; you know dere ain't a nigger in dis worl' goin' to stay 'way from a 'oman two weeks, less 'lone two months. Man, I ruther be dead."

Another thing, they will not give up alcoholics. Beer and whiskey are drunk just the same as before the attack by those who drink, and one can readily see the work of a genitourinary surgeon is an uphill road all the way with such patients to deal with, and because of their indifference to the gravity of the disease they go on spreading it in new soil whenever and wherever possible.

Dr. W. R. Jackson, an eminent surgeon of this city, in speaking of the negro relative to gonorrhea, once classified them as follows: Those who have had it; those who have it now, and those who are going to have it. And my dispensary and hospital work during the past seven years has proven that he is much nearer right than wrong, for I have found it almost exactly as he stated.

Replying to Dr. Steel's questions, I shall take them in the order in which they come:

"In your practice as compared to the white race: Is gonorrheal urethritis more prevalent among the adult negro?

Answer: Yes, the proportion will be easily ten negroes to one white man, and this is easily understood when you realize the difference in personal hygiene, mode of life, occupation, degree of education, and difference in sexual appetite of the two races.

"Are its sequelæ, pyosalpinx, pelvic abscess, etc., more common among the adult negro female population?

Answer: Yes. I am told by several surgeons that the proportion of pyosalpinx is six negroes to one white. Also, that the majority of the operations on adult female negroes are for gonorrheal pelvic lesions. To get a correct statement of facts in answer to this question, I refer you to Drs. W. R. Jackson, P. J. M. Acker, Wm. Mastin, C. H. Mastin, W. R. Sherrard, H. P. Cole, W. T. Henderson, E. G. Gavin, and H. T. Inge, all of Mobile, and all of whom have an extensive practice and experience in abdominal surgery.

"Is gonorrheal ophthalmia proportionately greater among the negro newborn?"

Answer: The proportion of negroes who employ physicians to attend them at childbirth is so small relatively that there is no way to arrive at any definite answer to this question. Nearly all negroes have midwives to deliver their babies, and these midwives, as a rule, are ignorant old women who have no more idea of asepsis and antisepsis than they have of the correct translation of Homer. It

is common practice among them to wash out a newborn baby's eyes with "chamber lye"—*i.e.* urine. Last year a negro woman brought a baby to the dispensary with a most virulent gonorrheal ophthalmia, and, upon questioning, it was learned the baby's eyes had been "cleansed" at birth with "chamber lye," choosing for this occasion the urine of an aunt, whose urine, it was claimed, made "chamber lye" especially suited for this purpose.

"Is the disease more prevalent among the city or country negro population?"

Answer: The city population. Reason: Segregation, dissipated mode of life, access to places of debauch, etc. The country negro works in the open air, as a rule, has a comfortable house to himself, leads a more sober, industrious life. His habits are cleaner, his environment purer, his ideals higher, his neighbors few, and, as a consequence, he, as a rule, is a more desirable citizen. In the cities where they crowd the fight for existence is harder, the temptations more and greater, and the environments, as a rule, the very worst for them.

"Is the disease as virulent in the colored race?"

Answer: Yes, and more so, for everything is done by the patient to make it so, viz., absolute disregard to treatment, persistence in sexual gratification, dissipation, poor nourishment, and unhygienic home surroundings. Everything which would tend to assist disease against nature.

"Is chronic gonorrhea and its sequelæ, prostatitis and seminal vesiculitis, more prevalent in the negro male?"

Answer: Yes; nearly every negro who comes under my observation has either one or both of the aforesaid sequelæ, and often many more.

"Is this condition responsible for sexual lawlessness mentioned in Dr. Taylor's article?"

Answer: There is no question that this condition has to do with sexual lawlessness, but to it alone cannot be laid the blame, for I am sure cocaine, poor whiskey, and bad influences have ruined many negro men, irrespective of venereal diseases. However, these all go hand in glove; usually where you find one the others are present, or soon follow. That the irritation caused from an inflamed prostate produces erections, creates a desire for sexual intercourse, and has often been the cause of sexual lawlessness is a fact. I know of two cases which could be attributed to that cause more than to any other, yet it would be too broad an assertion to say this is the whole cause.

Inasmuch as Dr. Steel confined his query to gonorrhea and its sequelæ, I have not devoted any part of this paper to syphilis and its ravages among the negro race, but I cannot refrain from alluding to it and quoting from an article entitled, "Some Economic Questions Relating to Syphilis," by Dr. Isadore Dyer, dean of the Tulane Medical School. This article appeared in the January edition of the *Southern Medical Journal*. Dr. Dyer is one of the greatest authorities on dermatology, and his opinion is certainly of greatest value. He goes on to say: "The South has its peculiar problem in this regard to the negro population, which it is hard to educate in sanitary or moral prophylaxis. The older our civilization grows the less virulent syphilis becomes, and it is chiefly among the negroes that we find the more malignant types of syphilis surviving to-day. Their habits of life under conditions of semi-poverty, immorality, exposure, and lack of hygiene, make the problem more and more difficult, and it cannot be solved without radical measures aiming at a forced treatment under hospital care. In an experience of over twenty years of hospital practice I have known of but one negro to take treatment for syphilis properly; the usual observation is that as soon as the evidences disappear treatment stops, and it is in these poor devils that the ravages of an insidious disease develops all the evils which follow its neglect."

The negro of the South belongs here now. He did not come of his own free will; he was brought here, and is here to stay a permanent fixture. And it is no one's desire that he should leave, so long as he fills the place of a citizen; but when his status is such that he is a public charge or a menace, then it is time to devise ways and means to remedy this evil.

Before he is taught the mathematical value of the parabolic curve, the distance from the earth to Mars, whether or not there are three or four dimensions, and how mathematically to prove it, or the chemical composition of salvarsan, he should first be taught life as it should be lived—not as any particular religious creed thinks it should be, but from a hygienic point of view. Do away with so many creed-teachers and give them teachers on sexual psychology and hygiene, beginning from the time they are twelve years old, and taught until their education is finished. It is a great pity some of the large-hearted philanthropists who bequeath fortunes for the education of the negro do not specify that about one-half of the amount donated be used in establishing such courses of study. Not only should these branches be taught in negro school and colleges, but in the institutions of learning for our own young people. This has been the fault in our white schools and colleges, not only in the South, but all over the United States. They have failed to teach young men how to live, and by this I mean they have allowed them to go on ignorant of the sexual side of life except as it could be learned from a fellow-student's personal experience. Legislators should pass laws requiring all persons suffering with venereal diseases be confined to hospitals until such time as they are found to be free of infection, and a law which should require all marriage licenses to have certificates of health attached before it is lawful for a minister, priest, or officer of the law to perform the marriage ceremony.

With the rigid enforcement of such laws we would soon have the negroes and whites alike appreciate the gravity of such infection and would put a check on promiscuous sexual intercourse. Those who ignored the law could not escape the marriage license provision.

The negro is not to blame for his disregard for the consequences of venereal diseases, for he is allowed to run at large with no restrictions save the advice of a physician (when he has one). Then, too, he hears white men discuss such matters as things of no consequence, therefore utter disregard for such conditions is but natural.

---

**Pregnancy and Tuberculosis.**—H. v. Bardeleben concludes that old, latent, inactive processes in the lungs do not furnish an indication for artificially terminating pregnancy. The patients with these lesions should, however, be kept under close observation, for in some of them the tuberculosis may light up in the later months. In cases with clinically active tuberculosis, excepting cases with simple apical catarrh, and in cases of apical catarrh after the fourth month, mere termination of gestation does not result in any special advantage to the woman.—*Zentralblatt für die Gesamte Gynäkologie und Geburtshilfe sowie deren Grenzgebiete.*

# A SIMPLE AND SATISFACTORY METHOD FOR REMOVING ADENOIDS AND TONSILS.

By WILLIAM WESLEY CARTER, A.M., M.D.,

NEW YORK.

LARYNGOLOGIST, GOUVERNEUR HOSPITAL; ASSISTANT SURGEON, MANHATTAN EYE, EAR, AND THROAT HOSPITAL.

In this short communication I wish to disclaim any desire to add to the confusion, which it seems to me can always be safely predicted whenever the subject of adenoids and tonsils is brought up for discussion.

I believe that no one operation will ever be generally accepted as being the best, for almost every operator has had sufficient experience with this very common ailment to have formed his own ideas. His technique, therefore, is based upon those ideas, and he performs the operation in the manner in which he believes he can do it most skillfully. It would therefore, be the acme of arrogance on my part to claim that my methods are superior to those of other operators, and should be generally adopted. I will not place myself in this unenviable position, but after many hundreds of operations on the tonsils, in which almost every method was tried out, I have adopted a technique which is simple, safe, and efficient, and attended by a minimum of trauma to the surrounding parts, and I believe that its many advantages will justify my temerity in offering a further contribution to the already overcrowded literature upon this much discussed subject, the importance of which, however, cannot be denied.

We will assume (1) that a palapable pharyngeal tonsil constitutes adenoids that should be removed. (2) That a diseased faucial tonsil is diseased in its entirety and should be removed completely, and that this can be done with assurance only when its capsule is included.

Two objects must be constantly kept in mind: A minimum of injury must be inflicted upon the tissues adjacent to the tonsils, and the offending growths must be thoroughly removed.

Too much stress cannot be placed upon the importance of protecting the palatal pillars. This protection should be afforded not only the muscular structures, but also the mucous membrane covering the pillars, for every injury means the subsequent formation of scar-tissue with its attendant contractures. Injury to the pillars, especially the posterior, may result in difficulty in swallowing, and in the return of fluids through the nose. This symptom is usually transient but may persist for some time. The injury to the voice, in my opinion, is never recovered from if the pillars have been badly mutilated.

Hemorrhage to any large extent can usually be avoided if we remember that it almost invariably comes from injured pillars, though the venous plexus at the base of the tonsil is sometimes responsible for very troublesome bleeding.

I must mention here that I never operate upon a throat without first examining by both inspection and palpation for an abnormally placed carotid, and on more than one occasion I have been rewarded for my pains by discovering a tortuous, pulsating carotid posterior to the tonsil, which I might have injured in the operation had I not been aware of its presence.

If injury to the soft palate is very severe, the resulting adhesions and contractures will prove a permanent injury to the voice and a constant menace to the health and comfort of the patient, unless they are relieved by an operation, and this is difficult and its results uncertain. On three occasions I have seen the nasopharynx completely closed by cicatricial tissue, due to the unskillful use of the Brandegee adenoid forceps. Such cases are deplorable, for the function of the damaged parts can never be restored to normal.

I have tried out on a sufficient number of cases nearly every procedure that has been advocated for the removal of tonsils, and in my hands the following technique has proved the most satisfactory.

*Instruments Used.*—(1) Denhart's mouth gag. (2) Tongue depressor. (3) Carter's spiral tonsil tenaculum. (4) Carter's sharp tonsil separator. (5) Eves' tonsil snare. (6) Gottstein's adenoid curette.

Most of these instruments are familiar to all, but I will call attention especially to the two instruments devised by me, as they have proved most useful, and their construction and application have never been fully described.

The *spiral tenaculum*, which was devised about three years ago, consists of two spiral prongs, each compassing half a circle. These are attached to a long slender shaft with octagonal handle. The prongs of this instrument are purposely made only a half circle in length in order that it may be easily and quickly engaged or disengaged by a half turn in either direction. This insures the safety and convenience of the instrument. In soft, mushy tonsils it is necessary to make several turns of the instrument in order to engage it in the firmer and deeper tissue which in such tonsils is found nearer the capsule. The instrument is especially useful in submerged cases. Here it can be introduced into the tonsil without engaging the pillars, even though only a narrow slit may separate the latter. When the instrument is engaged it gives perfect control of the tonsil, and enables one to adjust the snare with great precision. An important point in the use of this instrument is that a certain amount of torsion must always be kept up when traction is being made in order to overcome the reverse action of the inclined planes of the spiral prongs.

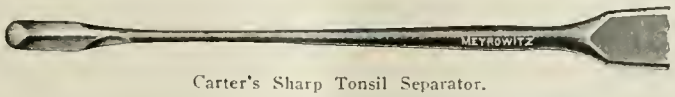
Carter's Spiral Tonsil Tenaculum

Recently there has appeared the inevitable modification of my instrument; this so-called modification has several turns of the spiral prongs. This design adds neither to the convenience, the efficiency, nor the safety of the instrument. It cannot be introduced or removed as quickly, it cannot hold the tonsil more firmly, and it is liable to be screwed through the tonsil and into the constrictor, thus endangering important structures. It is a form carefully and purposely avoided by me in devising my own instrument. I may add that my instrument as made by some manufacturers bears only a slight resemblance to the original model, which was made under my own directions. The instrument involves delicate

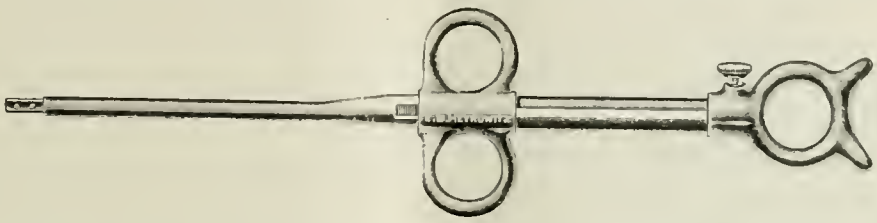
mechanical principles and should be correctly made in order to be effective.

The *tonsil separator* consists of a short beveled blade, curved on the flat. It is sharp on both sides and the end, and is used to cut through the plica and the mucous membrane along the margin of the pillars. It also serves as a lever to assist in lifting the tonsil from its bed.

*Description of the Operation.*—The patient, lying flat on the table, is thoroughly anesthetized with ether; the operator is stationed on the right of the patient, the anesthetist at the head, and the nurse with sponges on the left. The mouth gag is placed on the left side of the mouth. The throat is inspected for abnormal arterial distribution, and the location of the adenoids is definitely fixed by digital examination. The *spiral tenaculum* is then engaged in the right tonsil, which is pulled towards the median line. The *tonsil separator* is then introduced at the margin of the anterior pillar, and the mucous membrane is cut through, care being taken not to cut into the capsule. The posterior pillar is liberated in like manner. The separator is then passed under the anterior pillar, which is used as the fulcrum, and the tonsil is pried out, traction being made all the while by means of the tenaculum. The loop of the Eve's snare is then passed over the tenaculum and adjusted about the tonsil, which has been lifted entirely from its bed. When the loop is brought home it follows the line of cleavage between the capsule and the adjacent tissues and the tonsil is removed on the tenaculum with its capsule intact. The same operation is repeated on the left side.



Carter's Sharp Tonsil Separator.



Eve's Tonsil Snare.

The adenoids which have been previously located are then removed by one stroke of a well sharpened Gottstein curette, and the nasopharynx is wiped out with gauze wrapped about the index finger. This removes any fragments of adenoid tissue that may have been left, and also limits the hemorrhage from this area.

In conclusion I may say that my results by this method have been uniformly good and that I have never had a case of alarming hemorrhage nor complications resulting from injury to the soft palate.

69 West Fiftieth Street.

**The Action of Radium Upon the Blood and Upon Arterial Pressure.**—Giovanni Giacchi conducted his investigation upon 17 patients under treatment at the Policlinic Humbert I. The patients were exposed to the direct action of radium emanations in the emanatorium attached to the Institute of Clinical Medicine in Rome. The effects noted were as follows: There is a reduction in the amount of hemoglobin as well as in the numbers of red blood cells. Following the first exposure to the emanations there is an increase in the number of leucocytes, but following the later exposures there is a diminution. As regards the leucocytic formula it is noted that the polymorphonuclear neutrophiles in general increase in number but undergo a diminution following prolonged exposure to the emanations. The eosinophiles increase. There is a relative and an absolute increase in the basophiles. The large mononuclears increase in number. The effect of radium is to cause a diminution in arterial pressure.—*Il Policlinico.*

## Medicolegal Notes.

**Compensation of Health Officer.**—The Kentucky statute, section 2055, provides for the appointment of county boards of health and of a health officer, the amount of whose salary shall be fixed by the fiscal court at the time or immediately after his election. In no case is the health officer to receive from the county any compensation for his service other than the salary fixed by the fiscal court. The health officer resigned on account of insufficient remuneration. The board of health refused to accept his resignation, and during his term of office delegated certain of his duties to another, who was afterward appointed health officer. The latter claimed from the county compensation for services rendered both before and after his appointment as health officer. It was held that the county was not liable for services rendered during his predecessor's term of office, as that would be an evasion of the statute; and it was not liable for services performed by him after his own appointment, as these would be included in the salary fixed by the fiscal court. The salary so fixed must be reasonable, and relief could be had from an order of the fiscal court fixing an unreasonable salary by appeal to the circuit court and thence to the court of appeals.—Hickman County v. McMorris, Court of Appeals of Kentucky, 147 S. W. 768.

**Expert Testimony—Graduate Nurse.**—In an action for personal injuries a graduate nurse, who had nursed in familes, some of the members of which were epileptic, but who had never nursed in cases of epilepsy, was held not competent to testify as to whether certain symptoms indicate epilepsy. Any person could testify as to whether or not another had had a "fit," but it might require some considerable study of disease to be able to testify whether a "fit" was of an epileptic character.—Shawnee Gas & Electric Co. v. Hunt, Oklahoma Supreme Court, 122 Pac. 673.

**Burden of Proof.**—In an action against a surgeon for alleged negligence it was held that proof of the fact that a drain was left in the defendant's breast after the removal of a tumor imposed upon the defendant the burden of explaining that its presence there was not due to his negligence.—Evans v. Munroe, Rhode Island Supreme Court, 83 Atl. 82.

**Medical Authorities—Cross-Examination.**—In an action for personal injuries a medical expert had testified as to his opinion regarding the effect of the injuries in causing diabetes mellitus. It was held to be error to permit the cross-examination of the witness by questions as to medical authorities, the effect of which was to impress upon the minds of the jurors the idea that certain writers were men of eminence in medicine whose opinions were of value, and that their opinions differed from that expressed by the witness. The matter comes under the settled rule that neither medical books, though of recognized authority, nor the opinions of medical experts unless testified to by themselves as witnesses, can be received as evidence.—Allen v. Boston Elevated Ry. Co., Massachusetts Supreme Court, 98 N. E. 618.

**Expert Testimony—Mental Capacity.**—The proponents of a will and its contestants each called a medical expert on the question of the testator's mental capacity. Hypothetical questions were framed by each side, covering a period of four years and including many disconnected, trivial and insignificant circumstances, most of them as consistent with mental capacity as with mental incapacity. The opinions of the experts on the hypotheses respectively submitted to them were diametrically opposed. It was held that the surrogate, as trier of the fact, could not separate the facts so as to ascertain on which facts the experts relied, and must determine for himself the question of mental capacity.—*In re* Benjamin's Will, 136 N. Y. Supp. 1,070.

# MEDICAL RECORD.

New York, May 31, 1913.

## THE SERUM TREATMENT OF EPIDEMIC MENINGITIS.

AT the present time there probably remains little doubt in the minds of physicians of the efficacy of the serum treatment of epidemic meningitis. It is, however, not the less interesting and important to note just how valuable this treatment has proved to be. The Rockefeller Institute for Medical Research began the preparation and distribution of the antimeningococcus serum in 1906 and continued it until a short time ago when the work was turned over to the Department of Health of New York City. During this period the Institute collected the records of 1,294 cases which received the treatment. Flexner, in an article analyzing these records (*Journal of Experimental Medicine*, 1913, xvii, 553), presents figures based on the pandemic of 1904-9, which show that the mortality among patients not receiving the serum treatment varied from 42.5 to 90.0 per cent. with an average of not far from 75 per cent. The death rate remained remarkably constant in all parts of the world and seemed to depend more upon the virulence of the infecting organism than upon race or occupation. Among the reported cases the mortality was 30.9 per cent., a reduction of over 50 per cent.

A study of the figures makes this reduction all the more remarkable. All cases are included, early and late, fulminant and mild, those receiving the serum in modern hospitals at the hands of trained physicians and those treated in country districts by men little practised in the art of lumbar puncture. Under favorable circumstances with early and expert administration the mortality should be still further reduced. Figures are also given of two other series of cases treated with the serum. One in Greece of 186 cases with a mortality of 22.6 per cent., the other in three cities in Texas in 1911-12 where among 876 patients who received the serum the mortality was 25.5 per cent., while of 562 who were not so treated 77 per cent. died. Even in the fulminant cases in which death usually occurs in less than twenty-four hours, the serum not infrequently has a decidedly beneficial action. In the patients that recovered the complications and sequelæ were reduced in number; indeed the number of permanently injured among the serum-treated has become very small.

These figures carry their own argument and the conclusion from them can best be stated in the words of the first report of 1909. "In view of the various considerations presented, the conclusion may be drawn that the antimeningitis serum, when used by the subdural method of injection, in suitable doses and at proper intervals, is capable of reducing the period of illness; of preventing, in large measure, the chronic lesions and types of the infection; of bringing about complete restoration of health, in all but a very small number of the recovered, thus lessening the serious, deforming, and permanent consequences of meningitis; and of greatly diminishing the fatalities due to the disease."

## COAGULATION TIME.

MUCH interest has been manifested recently in the theoretical and clinical value of the coagulation time of the blood. A review of the literature shows thirty-four methods, together with their modifications, which have been devised in the attempt to render this property of the blood of practical clinical value. The devices for the determination of the clotting time are of three chief types: (1) the capillary tube, which forms the basis of the Vierodt and Wright methods; (2) the apparatus in which corpuscular motion is maintained by a current directed against the drop of blood, as in the Brodie-Russell chamber; and (3) the methods depending upon the contour of the drop of blood.

The factors entering into the clotting time of normal blood may roughly be classified into extrinsic and intrinsic. Of these the extrinsic are of greater importance clinically, because of their bearing upon technique. Within certain defined limits it is possible to control and reduce to uniformity the percentage of error if some standard can be adopted. The most striking of the extrinsic factors is contact with a foreign body. Blood free from contact with a foreign body, requires from seven to eight times as long to clot as blood drawn into a plain glass vessel. If the factor of air be added this time is nearly halved. The vital importance of small surface contact, or at least uniformity of surface exposed, is readily apparent. Perfect cleanliness of apparatus should be insisted upon. Opinion varies as to the influence of the size and shape of the drop, when the drop method is used. The amount of blood withdrawn, whether a small drop or a test tube full, cannot be disregarded. Mechanical disturbance, whether through handling, direction of air currents, the use of horsehair, silk, or mere tilting of the drop, tends to hasten coagulation time. Evaporation hastens it. Temperature near that of the body is desirable, as a slight fall below or rise above that retards or hastens the end point of the process. Any dilution of the blood, even if the diluent be isotonic, tends to lengthen the time of clotting.

The manner of drawing the blood has caused much discussion, (1) as to the part punctured, (2) the depth and character of the wound, and (3) contact with the tissues. Several reliable investigators have found that the part punctured has no influence on coagulation if the drop used is a freely

flowing one, and no pressure is used in securing it. The depth of the wound is not a factor if free bleeding is obtained. When a blunt instrument is used and only relatively free or poor flow results, the excessive tissue juice and slow flow hasten clotting. A sharp instrument, a free flowing drop, and absence of pressure are essential to accurate results. Contact with the tissues has to do, not only with the wound edges, but with the presence of a portion of an old clot, tissue juice, and the skin. Of the intrinsic factors, temperature, barometric pressure, humidity, and time of day are of doubtful influence. Blood pressure, agglutination, and amount of hemoglobin are unimportant. A low platelet count seems to be a factor in some cases, in others not. Viscosity involves a slow flow, and a deeper (higher) drop in the drop methods.

The pathological significance of coagulation time clinically is as yet indeterminate. It is variable in typhoid fever, being hastened especially in cases with thrombosis. It is hastened in myelogenous leukemia, diabetes, and endocarditis. It is delayed in hemophilia, purpura hemorrhagica, lymphatic leukemia, and splenic anemia. In diseases of the liver and gall-bladder the decreased coagulability seems to vary directly as the depth and intensity of the jaundice. Of the acute infections, lobar pneumonia and septicemia show the most consistent and longest delay of clot formation. The above results have been obtained by a number of observers, the latest to confirm them being Lee and White of Boston (*American Journal of the Medical Sciences,* May, 1913). They took blood directly from the arm vein with a syringe. While their method has many good points, there is too much contact with foreign bodies in the transference and handling of the blood for any great accuracy.

Personal equation as yet plays too great a part in the interpretation of the end-point of the clotting process. The results obtained by the multiplicity of coagulometers render difficult any exact comparisons by the different workers. In view of the large amount of material handled, and the extensive work done by the many investigators in this field, the nonconfirmatory nature of the results is unfortunate. Coagulation times, varying from two to thirty minutes in normal blood, leave too wide a latitude for accuracy. The adoption of some uniform procedure, or the devising of some technique minimizing the factors of error, and yet of sufficient practical value for clinical purposes, is much to be desired.

## SEXUAL INSTRUCTION.

For some time past there has been a considerable amount of discussion with regard to sexual instruction in schools. Many have argued that it is largely due to the prudishness which has prevented the teaching of sexual matters to the young that immorality, prostitution, and their awful aftermath flourish so exceedingly. It is now recognized that venereal diseases are at the root of most diseases and that if these are allowed to continue unchecked in time modern civilization will be sapped at its foundations. It has been also contended that Great Britain and America have been and are the two countries in which such things must not be mentioned to the young. In fact, it is only within the last few years that they have been mentioned in public at all. Now a change has come over the attitude of the medical profession and public with regard to this matter and a crusade against venereal diseases appears to be imminent.

Various writers and speakers have earnestly urged that sexual instruction be given in schools, but there is little unanimity of opinion as to the form this instruction should take. Some think that young children should be taught elementary physiology, others hold that the process of reproduction as it occurs in plants and animals should be taught as a matter of course just as any branch of physics might be taught; but most believe that the teaching should not go far.

Under the title "What Every Child Wants to Know," Emilia v. Kanthack de Voss of Hamburg, Germany, has contributed an eminently commonsense paper on the subject of sexual instruction to the young to *The Child* for April. She wisely points out that although it may be fitting that the home should be the fount of such instruction, and that while it is absolutely necessary to be truthful to a child, truthfulness does not necessitate premature revelations. Such revelations might be productive of infinite harm to a child's developing intelligence. Furthermore, attention is drawn to the fact that education is not training, and that the training a child receives in his own home is what gives him his attitude for ever after toward life and all that is in store for him, his attitude, indeed, toward the world, the flesh, and the devil. Training, too, is mainly subconscious; a child is above all imitative, and the training received when young, that is by mothers or those who stand in the place of a mother, will last throughout life. Therefore, perhaps, it should rest with the mother as to how much of the truth she should tell to an inquisitive child. Strong meat is not for babies, and, arguing in the same way, one must not tell a child more of sexual matters than its intelligence warrants. Mrs. de Voss truly says that there are other ways of influencing and protecting children apart from giving definite explanations. Love and trust in a mother will often prevent a child or youth from yielding to temptation. Let biology be taught in schools and let the teaching be correct and explicit but "sex hygiene" as a school subject can never repair the omission of early home training.

Of course, it is frequently taken for granted that mothers are not competent to give instruction to their children on sexual matters and no doubt this is to some extent true, but as the writer in *The Child* remarks, "It is not fair to dub parents, as a class, wholly incompetent to make clear to their own children matters about which they must have more inside knowledge than unmarried teachers." It is well that this subject should be thoroughly ventilated by parents, teachers, medical men, and sociologists, and it is especially refreshing to read so able a presentation of the matter as that given by Mrs. de Voss.

## EXPENDITURE OF PUBLIC MONEYS FOR HEALTH WORK.

The adjournment of the various legislative bodies usually brings up the subject of appropriations, and it is interesting to note that with an exasperating uniformity the appropriations for the health and sanitary departments is always particularly niggardly. The public does not yet seem to realize or recognize the monetary value of public health, except when the lack of it causes them an actual financial loss, perhaps through some stringent quarantine restriction. Whether the death rate is higher or lower at a particular time makes little difference to the public, if, indeed, it is aware of it. While they are shocked at a severe railroad or other disaster, they do not seem to be affected by an equal number of deaths from even an epidemic. And this is not from a lack of sympathy or generosity, because the State as well as private individuals respond generously for the relief of suffering following on disaster—more than they would if the disaster were an epidemic of a particularly fatal disease.

A comparison of the moneys spent by the State for the public health and on other public endeavors, will throw some light on this subject. In 1910, the City of New York, for example, spent about 148 million dollars in governing that city, and only 2½ millions for its health. In the same year it spent about 8 million dollars for its fire department, though its fire loss was only about 9 millions. The loss of life in the same year from preventable diseases was about 33,200 (total deaths from all causes 76,742), and if each life is valued, according to Irving Fisher, at $1,700, then the loss in dollars is over 56 millions—and against this loss only 2½ millions were spent in efforts to conserve. Fisher estimates that if each life is valued at $1,700, and the average productive capacity of each individual is $700 annually, then the total loss in the United States, through preventable disease exceeds one and one-half billion dollars annually.

It has been repeatedly stated, and truly, that the United States Government spends more money on the protection of its cattle industries than on its health departments. Every one, no matter of what medical creed, concedes the necessity of an adequately organized department for that purpose, except the ignorant or those against it from selfish motives. When it was attempted to create a United States Department of Health, it was attacked even on constitutional grounds, but President Taft's commentary on this question should have settled this contention for all time. He said: "There is nothing in the constitution especially about hogs or cattle or horses; and if out of the public treasury at Washington we can establish a department for that purpose, it does not seem to me to be a long step or a stretch of logic to say that we have the power to spend money in a Bureau of Research to tell how we can develop good men and good women."

When will the public see the light in its own interest? The suspicion it has of medical men is not justified, for in what other branch of human endeavor do we see its workers trying with all their might to reduce their business? The public should be, and no doubt will be in time the foremost advocates of medical research and health measures. At present all the work in that direction is due to the generosity of a few private, but public spirited, individuals.

---

### Pemphigus Malignans Cured by a Single Intravenous Injection of Blood.

Pemphigus, a potentially fatal malady, has long been studied in the hope of elucidating the nature not only of this bullous dermatosis itself, but of all similar eruptions which appear to herald the presence of an underlying severe blood dyscrasia. Some of the members of this group are to be found in the cutaneous expressions of pregnancy toxemia. These eruptions first yielded to a serum from normal gravidæ and later the method was extended to the treatment of nongravid victims of pemphigus with ordinary serum. During the past year Heuck reported a severe case of chronic pemphigus, cured, or at least greatly improved, by a series of 34 injections of from 10 to 30 cm. of normal human serum. In the *Muenchener medizinische Wochenschrift* for April 22, Praetorius briefly reports a case of the most severe type of chronic pemphigus cured apparently by a single injection of normal human blood which had not been defibrinated. The eruption ceased and no relapse has occurred during eight months. This result overshadowed greatly those accomplished only after much delay with defibrinated and centrifuged blood. The author did not use the modern technique of arm to arm transfusion, but simply withdrew blood from the donor's body and injected it forthwith into the cubital vein of the recipient.

---

## News of the Week.

**Anti-Cancer Society.**—On May 15, in New York, a committee of physicians representing a number of medical societies met with a committee of laymen for the purpose of forming an association to conduct a world-wide campaign of education on the subject of cancer. The following officers were elected: *President*, George C. Clark, New York City; *Vice-Presidents*, Dr. Clement Cleveland, New York; Dr. Lewis M. McMurtry, Louisville, Ky.; Dr. Edward Reynolds, Boston; Dr. Edward Martin, Philadelphia; Dr. Llewellys F. Barker, Baltimore; *Secretary*, Thomas M. Debevoise. The executive committee is composed of Dr. George Brewer, New York City; Dr. F. F. Simpson, Pittsburg; Dr. Livingston Farrand, New York City; Dr. Joseph Bloodgood, Baltimore; Dr. A. D. Bevan, Chicago; Dr. Le Roy Broun and Dr. Howard Lilienthal of New York City; Dr. Jeff Miller, New Orleans; Dr. James Ewing, New York City; Dr. Charles Powers, Denver; Dr. Reuben Peterson, Ann Arbor, Mich.; Dr. William M. Studdiford, New York City; Dr. Frederick J. Taussig, St. Louis; Dr. Howard C. Taylor, New York City; John E. Parsons and V. Everit Macy. The following medical societies were represented at the meeting: the American Dermatological Association, American Surgical Association, American Laryngological Association, American Otological Association, American Genito-Urinary Association,

American Gynecological Society, American Association of Pathologists and Bacteriologists, American Orthopedic Association, American Ophthalmological Society, American Neurological Association. The association plans, by means of magazine articles and pamphlets to be distributed by visiting nurses, social workers, etc., and by lectures to be delivered before women's clubs, to enlighten the women of the country on the subject of cancer and the importance of prompt treatment.

**Wood Alcohol and Blindness.**—The fourth annual report of the New York Committee on the Prevention of Blindness states that during the past year in this State alone thirteen persons were made blind for life and four persons were killed by either drinking wood alcohol or inhaling its poisonous fumes. The committee urges the passage of legislations restricting or regulating the use of this poison.

**Hospital at Aix-les-Bains.**—The Leon Blanc Hospital at Aix-les-Bains, France, which was donated to the town by the late Mr. J. Pierpont Morgan, was formally opened on May 15. The hospital was given by Mr. Morgan in memory of his physician, Dr. Leon Blanc.

**Civil Service Examinations.**—The New York Civil Service Commission announces that examinations will be held on June 14, 1913, for the purpose of filling vacancies in the following positions:

Woman physician in the New York State Training School for Girls, Hudson, N. Y., at a salary of $1,200 a year and maintenance. Also, assistant woman physician, at a salary of $1,000 a year and maintenance. Candidates for these positions must be graduates of a registered medical school with at least one year's hospital experience or three years' general practice after graduation.

Lecturer on oral hygiene (male) in the State Department of Health, at a salary of $3,000 to $3,500. Candidates must be graduates of legally chartered dental colleges recognized by the State Board of Regents, and must have practised their profession in the State of New York for at least five years.

All candidates must be citizens of the United States. Applications for the examination must be filed in the office of the Commission before June 6. Blanks may be obtained before June 4 on application to the State Civil Service Commission, Albany, N. Y.

**Proposal for a Joint Investigation of the Doctrine of Similars.**—A committee of the American Institute of Homœopathy, under the chairmanship of Dr. Herbert Dana Schenck of Brooklyn, has sent a communication to the president and secretary of the American Medical Association, asking in behalf of the Homœopathic physicians of the United States for a joint investigation of the scientific merits of the method of drug relation expressed by the formula "Similia Similibus Curentur." It is suggested that the American Medical Association appoint a committee of five to meet a like committee from the American Institute of Homœopathy to discuss this subject with a view of attempting a demonstration of the truth or falsity of the theory of similars. It is further suggested that the joint committee study the physiological action, in large and small doses, of a definite number of drugs in common use by the members of both societies, this investigation to be under the auspices of some research laboratory like the Rockefeller Institute in New York or the McCormick Institute in Chicago; and finally make a comparative trial of the therapeutic efficacy of these drugs, given according to the various methods of administration, in some of the large public hospitals.

**Dr. Ludwig Weiss** has been appointed consulting physician in the Dermatological Department of St. Mark's Hospital, New York City.

**Dr. Enrique Nunez** has been appointed Minister of Sanitation in the Cabinet of President Menocal of Cuba.

**City Vital Statistics.**—During the week ending May 17, there were reported in New York 1,531 deaths, giving a death rate of 14.75 per thousand, as against 1,463 deaths and a rate of 14.75 during the corresponding week of last year. The increases occurred almost entirely in diseases of a chronic nature; thus, the deaths from organic heart disease were increased by 44; from tuberculosis by 22; from disease of the kidney by 16. Measles showed a decrease of 11 deaths, lobar pneumonia of 15, and bronchopneumonia of 21. The New York Department of Health estimates that on July 1, 1913, the population of the city will amount to 5,372,983. It is also estimated that of this population only 15.8 per cent. is of native parentage, while 38.8 per cent. is of foreign parentage though native born, and 45.4 per cent. is foreign born.

**Medical Graduates.**—The fiftieth annual commencement exercises of the New York Medical College and Hospital for Women were held on May 22, when nine young women received degrees.

**St. Vincent Hospital Alumnæ Association.**—Announcement is made of the establishment at 269 West 12th Street, New York, of a registry for nurses by this association, under the charge of Miss Katherine Donovan.

**Annual Meeting of St. Vincent's Hospital Staff.**—The annual meeting of the medical staff of St. Vincent's Hospital was held at the hospital on May 21st, His Eminence Cardinal Farley presiding. The medical and surgical appointments for the year were confirmed. Dr. José M. Ferrer was elected President of the Medical Board and Dr. Charles E. Nammack, Secretary. After an address by the Cardinal, the report for the year 1912 was read and approved.

**Charitable Bequests.**—By the will of the late Samuel Teller Benner of Philadelphia the sum of $5,000 is bequeathed to the Presbyterian Hospital of that city for the endowment of a free bed.

The Montefiore Home, New York, receives a bequest of $5,000 by the will of the late Mr. Samson Fried of this city.

Bequests of $2,000 each are made to Mount Sinai Hospital, the Montefiore Home, Beth Israel Hospital, and the East Side School for Crippled Children, New York, by the will of the late Mr. Albert Krower.

Mr. Theodore Goetze, who died recently in Brooklyn, made provision in his will for a number of charities. Among them, the German Hospital, New York, receives $8,000; Seton Hospital, St. Francis Hospital, and St. Joseph's Hospital, $5,000 each; and St. Mark's Hospital, $5,000.

The Methodist Episcopal Hospital, Brooklyn, $3,500 by the will of the late Miss Elizabeth M. Carpenter.

The Polyclinic Hospital has recently received the endowment of three beds in its general wards, and an additional donation of $1,000 from Mr. A. H. Troescher, in memory of his friend, the late Andrew Blum.

By the will of the late Dr. Daniel B. Bower, a dentist of Boyertown, Pa., the sum of $25,000 is bequeathed as a fund for the establishment of the Bower Charity Hospital.

**Bellevue Alumni.**—The Class of '98 of the Bellevue Hospital Medical College held their fifteenth annual reunion on May 10. Dr. Anthony Bassler acted as toastmaster, and short speeches were made by several members of the class.

**Research Fellowship.**—The Medical Department of University of Pennsylvania has received from Mr. Stevens Hecksher of Philadelphia a gift of $10,000 for the establishment of a fellowship in medical research as a memorial to the late Mrs. Hecksher.

**Hospital Anniversary.**—On May 12, St. Agnes Hospital, Philadelphia, celebrated with appropriate ceremonies the twenty-fifth anniversary of its foundation.

**New Hospital Building.**—The New York Orthopædic Dispensary and Hospital has purchased as a site for its new buildings a plot running from 421 to 435 East Fifty-eighth Street and from 420 to 426 East Fifty-ninth Street. A large building is to be erected as soon as possible.

**Medical Society Elections.**—American Association for Promoting Hygiene and Public Baths.—A meeting of this association was held in Baltimore on May 13 to 15, when the following officers were elected for the ensuing year: *President,* Dr. Simon Baruch, New York; *Vice-President,* Mr. Thomas M. Beadenkopf, Baltimore; *Secretary,* J. Leonard Mason, City Hall, Newark, N. J.

Canadian Medical Association.—The forty-sixth annual meeting of this association will be held at London, Ontario, on June 24 to 27, 1913, under the presidency of Dr. Hugh A. McCallum of London. Dr. J. Alexander Hutchinson of Montreal will deliver the address in surgery; Dr. T. S. Cullen of Baltimore, the address in gynecology, and Dr. Llewellys F. Barker of Baltimore, the address in medicine. An interesting program for the different sections of the association has also been arranged.

Texas State Medical Association.—At the forty-fifth annual meeting held in San Antonio, the following officers were elected: *President,* Dr. Marvin L. Graves, Galveston; *Vice-Presidents,* Dr. John H. Foster, Houston; Dr. J. C. Anderson, Plainview, and Dr. R. R. White, Temple; *Secretary,* Dr. Holman Taylor, Fort Worth; *Treasurer,* Dr. W. L. Allison, Forth Worth. Houston was selected as the place for the 1914 meeting.

Oklahoma State Medical Association.—The following officers were elected on May 15 at the annual meeting held at Enid: *President,* Dr. James M. Byrum, Shawnee; *Vice-Presidents,* Dr. Dock Long, Duncan; Dr. J. T. Slover, Sulphur, and Dr. J. H. Barnes, Enid; *Secretary,* Dr. Claude A. Thompson, Muskogee. The next meeting will be held at Guthrie.

Franklin District (Mass.) Medical Society.—At the annual meeting held on May 14 at Greenfield, the following officers were elected: *President,* Dr. Charles F. Canedy, Greenfield; *Vice-President,* Dr. J. E. Urquhart, Ashfield; *Secretary-Treasurer,* Dr. W. K. Clark, Greenfield.

Worcester Dstrict (Mass.) Medical Society.—The following officers were elected on May 14 at the meeting held at Worcester: *President,* Dr. Homer Gage, Worcester; *Vice-President,* Dr. Frank H. Clapp, North Grafton; *Secretary,* Dr. Earnest L. Hunt, Worcester; *Treasurer,* Dr. George O. Ward, Worcester.

Ohio Homeopathic Medical Society.—At the meeting held in Marion on May 14 and 15, the following officers were elected: *President,* Dr. Frank Webster, Dayton; *Vice-Presidents,* Dr. George Irvin, Orrville, and Dr. Ella G. Hunt, Cincinnati; *Secretary,* Dr. R. O. Keiser, Columbus; *Treasurer,* Dr. T. T. Church, Salem.

**Obituary Notes.**—Dr. John DeWitt Nelson of New York, a graduate of the College of Physicians and Surgeons, New York, in 1875, died recently at his home, aged 65 years.

Dr. Louis G. Le Beuf of New Orleans, a graduate of the Medical Department of the Tulane University of Louisiana in 1887, formerly coroner of Jefferson Parish, president of the Orleans Medical Society, and a member also of the American Medical Association, and the Louisiana State Medical Society, died at Pass Christian, La., after a long illness, on May 5.

Dr. David Coggin of Salem, Mass., a graduate of the Harvard Medical School in 1868, consulting ophthalmologist to the Salem Hospital, with which institution he had been connected since its foundation, and a member of the Massachusetts State and Essex County Medical Societies, died at his home on May 7, aged 69 years.

Dr. John William Kyger of Kansas City, Mo., a graduate of the University of Virginia, Department of Medicine, in 1868, and a member of the Missouri State and Jackson County Medical Societies, died at his home on May 5, aged 64 years.

Dr. Richard Francis Murphy of New York, a graduate of the New York University Medical College in 1889, died at his home from apoplexy, on May 10, aged 51 years.

Dr. Edward W. Carhart of Brooklyn, N. Y., a graduate of the Albany Medical College in 1898, died at his home on May 16, aged 56 years.

Dr. James B. Olmstead of Portland, Ore., a graduate of the Pulte Medical College, Cincinnati, O., in 1881, died in St. Elizabeth's Hospital, Yakima, Wash., from uremia, on May 8, aged 56 years.

Dr. J. Williams Henry of Brooklyn, N. Y., a graduate of the Georgetown University School of Medicine, Washington, in 1866, died at his home after a long illness, on May 16, aged 83 years.

Dr. Elmer E. Brown of Philadelphia, Penn., a graduate of the Jefferson Medical College in 1897, a member of the Pennsylvania State and Philadelphia County Medical Societies and the Philadelphia Obstetrical Society, a director of the Garretson and Samaritan Hospitals, and vice-president of Temple University, died at his home May 23, aged 53 years.

Dr. David Engelman of Easton, Penn., a graduate of the Jefferson Medical College in 1864, a member of the Pennsylvania State and Northampton County Medical Societies, and at one time president of the State Board of Health, died at his home on May 14, aged 77 years.

Dr. Annie M. Hawley of Pughtown, Penn., a graduate of the Hahnemann Medical College and Hospital of Chicago in 1873, died at her home on May 11.

Dr. Joseph Warren Dossett of Wilmer, Ala., a graduate of the University of Alabama Medical Department in 1903, died in the Providence Hospital, Mobile, on May 9, aged 56 years.

## A SHORT-CIRCUIT WARNING.

*To the Editor of* The Medical Record:

Sir:—In the Medical Record for May 17, 1913, Dr. A. E. Rockey, under the above caption, makes elaborate criticism of the reference to the short-circuiting bowel operation in my article, published in the issue of April 12. Dr. Rockey's criticisms are correctly made and the point well stated, from the standpoint of the Lane operation. The dangers and difficulties to which he calls attention have all been experienced by those of us who are interested in this work, and I had not thought of leading any inexperienced surgeon into temptation by making the work seem simple.

In view of the fact that the short-circuiting operation is to be done more and more in cases of chronic constipation in which intestinal stasis leads to numerous toxic conditions, from neuralgia to melancholia, I have tried to simplify the operation in such a way that it would not frighten the general practitioner, who now has a tendency to run off in alarm when we speak of short-circuiting the bowel instead of applying liniments in cases of rheumatism.

The operation in which I am interested at present can really be done through a short incision. The ileum is not divided at all, but is brought down to the distal part of the sigmoid, or the proximal part of the rectum, and there united after a doorway has been made. The tendency to progress of contents of the ileum along a natural route, disregarding the doorway, is overcome by angulating the ileum for a couple of inches distally from the doorway, two or three sutures serving to retain the ileum in its angulated form. To guard against the filling of the colon by antiperistalsis, as described by Mr. Lane, and as occurring in the practice of various surgeons at present, the sigmoid is angulated for a short distance proximally from the doorway. This angulation, like that of the ileum, is maintained by the introduction of two or three sutures at points where they are evidently needed for the purpose.

In my last case the operation was done with the aid of a special instrument devised for the purpose. This instrument carries jaws, one of them fenestrated. It is passed up the rectum to the vicinity of the sigmoid; one jaw remains in the large bowel, the other is passed through a slit in the side of the large bowel through a corresponding slit in the ileum; the jaws are then snapped together and left to cut their way through slowly and make a doorway, avoiding most of the hemorrhage and soiling of the peritoneum, and expenditure of time, belonging to the Lane operation. In this particular case the forceps cut through at the end of about 48 hours, and the instrument was removed from the rectum.

I will show a cut of this instrument in the near future, although it was my intention to wait until it had been employed in a certain number of cases before presenting it for consideration by the profession.

Robert T. Morris, M. D.

616 Madison Avenue, New York City.

## OUR LONDON LETTER.

(From Our Regular Correspondent.)

MEDICAL MEETING IN THE CITY—LONDON UNIVERSITY—GOUT AND RHEUMATISM—TUBERCULIN FOR OUT-PATIENTS—BLOOD PARASITES—OBITUARY.

London, May 9, 1913.

Yesterday there was a meeting of city practitioners held at the Guildhall, over which Sir T. Crosby presided. The object was to discuss the working of the Insurance Act. There were present men who had accepted and others who had refused panel service. Dr. Strong and Dr. Scanlan were chosen to represent the city on the Medical Advisory Committee, and Dr. Gillies was appointed chairman of the city committee. It was resolved that the allocation to one medical man of several thousands of patients under the Act rendered honest treatment impossible, and degraded the conception of professional duty. The meeting therefore asked for a reasonable limit to be put on the number admitted on the panel of any individual practitioner.

Wednesday was presentation day at the London University, and was celebrated by what were said to be the customary ceremonies. There is some difficulty in satisfying oneself as to what are customary in an institution the constitution of which seems continually changing. The annual report was read, in which the question of the new site was attended to and the preference of the Royal Commission for Bloomsbury half-heartedly endorsed. The event, however, was the address of Sir P. Magnus, who showed to the delight of not a few the objections to these continual changes. During its 80 years of existence it has attained no permanent form. Within the last week or two the report of the Royal Commission has been issued, and is a careful and powerful exposition of university requirements and work in general, but says the organization of this is "fundamentally defective." Yet only about a decade ago a commission of equal authority had set up this organization, which was to make it the "greatest institution of the kind in the whole world." I can look back more decades than Sir P. Magnus, but with the same doubts and disappointments, and considering the many remedies proposed for the constitution, which has offered fresh "defects" to every new set of doctors, repeat his reminder of the unfortunate patient on whose tombstone was inscribed: "I was well, I wanted to be better, and here I am."

The etiology of gout and rheumatism from the bacteriological standpoint was the subject of a paper in the Medical Section (R. S. M.) by Dr. Lyon Smith. He based it on nearly 200 cases observed in the last 3 years. They included single and multiple arthritis, periarthritis, aponeurositis, neuritis, and perineuritis. They were traced to chronic lesions serving as foci of infections, mostly in the alimentary mucous membrane, though the renal lining also furnished cases, as did the skin. Pyorrhea alveolaris was the most frequent form, and the importance of recognizing its precursor—marginal gingivitis—was pointed out. All the common microbes associated with chronic inflammatory conditions had been met with; so were some of the more specific. But most of the cases seemed to be due to mixed infections. This increased the difficulties of treatment by rendering the immunizing process more complicated. Clinical responses to tentative inoculations had been quite significant. In

one unusual type of case the diphtheria bacillus seemed to be the cause, and antitoxin was used with striking results, symptoms being alleviated by inoculations far short of complete immunization. It could be shown that ferments of certain bacteria acting on food-stuffs caused cleavage of proteins, hydrocarbons, and carbohydrates, and could give rise to various organic acids, *e.g.* lactic, acetic, butyric, hippuric, oxalic. It did not seem logical to cut down one section of the diet table in the hope of killing the parasite by starving the host. A more rational plan was to try and raise the specific immunity of the host to whichever pathogenic organism beset him most actively. Our models for such efforts were the methods of the research laboratories which had proved most successful in producing such immunities.

At the same meeting (22d ult.) Dr. T. D. Lister gave his experience of consumptives treated with tuberculin while out-patients, and pointed out the difficulties of doing so. The first was to settle what observations could be made. Patients were supplied with a thermometer and instructed to take their temperature by the mouth on waking, usually about 7 A.M., before eating or drinking, and again in the afternoon, one hour after tea. When not verified by a medical man or district nurse the accuracy of the record must be estimated by its own evidence. In doubt, he did not begin the treatment until a further chart. He kept the charts some weeks before giving tuberculin—one week's interval did not give a scientific basis for out-patients. In the wards they were under continual observation, and there was not the irregular attendance, the unfavorable conditions as to employment, the varying nutrition and so on. So when reactions occurred—which he endeavored to avoid—there was not the same control as with in-patients. Some, however, followed their instructions, and for them (too few) it was justifiable and often expedient to try out-door treatment, but the selection of suitable cases was difficult, for immunizing ability depended on the state of the blood and tissue cells, while nutrition was an important point. He felt sure some unfavorable results he had seen were due to failure of nutrition, and that other favorable ones were due to the supply of proper food. Physical signs in an infective disease causing gradual destructive change were less important than the resisting power of the patient towards the infection. A limited severe lesion and chronic fibrosis, even with a cavity, was better than diffuse infiltration and subacute symptoms. It is established that nine-tenths of our population have recovered from tubercle infection. So our improved diagnosis will detect many cases that will get well. A small dose at first—quite experimental—was best, the patient being warned to be careful about temperature, and rest in bed 24 or 36 hours on any rise. The dose should be only gradually increased until it became full in the twenty-fourth week. Unfortunately, much unsatisfactory administration was going on. Series of doses prepared by commercial firms were issued to practitioners, who used them without regard to their toxicity. A strong protest against indiscriminate use was necessary. Tuberculin was a toxin—not an antitoxin. A rise of temperature after a dose contraindicated any increase, and if the rise remained to the evening before the next attendance the dose should be omitted. The following week if it kept normal the previous dose could be given, and the week following that it could be increased, but only if the temperature remained normal. If this caused reaction the next dose must be less. After a reaction no dose should ever be given until the temperature had remained quite normal for several days under the patient's ordinary conditions of life. When a successful result had seemed to be attained the patient was advised to return at one or two months' intervals for repetition of the maximum dose he had had. After-care of these cases was the same problem as prevention. He confessed to little faith in the permanence of immunity after an attack of open tuberculosis by any method, but tuberculin treatment kept the patient a long time under guidance. He used the tuberculin prepared by Dr. Hunt, pathologist to the hospital, in a series of decimal dilutions corresponding to 0.0001, 0.001, 0.01, 0.1, 1 mg. bacillary substance in each 1 cc. It was diluted with 0.8 per cent. salt solution containing 0.5 per cent. carbolic acid and heated to 58° C. for half an hour. The injections were made in the arm, previously washed with a lysol solution. The puncture was dried and sometimes covered. A printed card of instructions was given to each patient. There was no need to cease other treatment, but he gave no opiates of any kind for cough. Menthol and licorice pellets were usually sufficient.

A lecture on blood parasites was given on the 2d inst. by Mr. H. G. Plimmer at the Royal Institution. He said knowledge of the subject began with Laveran's discovery of the malaria parasite. This belonged to the protozoa, as do most of the blood-parasites. That order accordingly deposed the bacteria from the proud position of causing all the ills that man has to bear. The earliest on which a blood parasite was observed was 1841, when Valentin detected one in a fish's blood. Up to the present a number have been discovered and believed to cause disease. But dangerously little is really known about them. It is therefore imperative not to make our account of them accord too closely with other facts, as later discoveries may show that partial knowledge has led to erroneous conclusions. The lecturer said that he had examined the blood of over 6,000 animals during the past 5 years, and he found parasites in 587; in 297 of the animals (which came from all parts of the world) he found the parasites for the first time. He showed a number of them on the screen, at the same time warning his hearers that they were enormously magnified. To help them appreciate their minuteness he told them that a 6-foot man magnified as much would appear more than 20 miles tall. In the course of his lecture Mr. Plimmer paid a tribute to Obermeier's inoculation of himself with the spirochete of relapsing fever, which proved fatal to him.

Dr. J. C. Thorowgood died on the 2d inst., aet. 81, at Bognor, to which he retired more than 10 years ago on account of failing health, to the great regret of many professional friends, among whom I claim a place. His London career as a physician was successful, and in every society he was welcome as a type of a learned, upright gentleman and worthy representative of the profession. He qualified in 1855, took the M. D. Lond. in 1857, and after spending some months in the provinces and abroad was elected on the staff of the City of London Hospital for Diseases of the Chest, and on the West London Hospital, to both of which he became consulting physician after long service, as he also did to the National Hospital for Consumption.

For a time he lectured on materia medica at the Middlesex Hospital School, and filled other appointments. Perhaps the chief of these was at Apothecaries Hall, where he was long an examiner and eventually president of the Board of Examiners. His book on the "Climatic Treatment of Consumption" was one of the earliest advocating bracing resorts, and his conclusions have since been generally endorsed. He delivered the Lettsomian lecture in 1879 on "Bronchial Asthma," a subject which much interested him. He also published "Notes on Asthma" and the "Hypophosphates in Consumption."

Dr. Herbert Manley, A.M., M.D., Cantab., and M. O. H. for West Bromwich, died on the 6th inst., aet. 57. He was a D. P. H. of the Conjoint Board, took a great interest in Medical Defence Union, of which he became V. P., and filled a number of offices in West Bromwich. He had been lecturer at the Birmingham Technical School, and was highly esteemed as an authority on hygiene and the relations of medicine to the public health. He was, besides his medical position, a barrister at law.

Mr. A. P. Hills, a leader in medical politics, M. R. C. S., 1850, much interested in the Incorporated Practitioners' Society, of which he became V. P., died on the 6th inst., aet. 57.

5. Artificially Dried Casein—Preliminary Investigation. H. I. Bowditch.
6. Transduodenal Choledochotomy. J. C. Hubbard.
7. Recurrent Variola. E. F. Cody.

1. **The Urinary Excretion of Formalin.**—G. W. Smith has found that Burnam's test for formaldehyde in urine is definitely positive when this substance is present in the strength of 1 part in 40,000 or more. The urine should be examined as soon as possible after it has been voided. A negative test at one time does not prove that formaldehyde is never liberated. From the evidence at hand the author believes that formaldehyde is liberated from the hexamethylenamine by the acids of the urine, not by a specific function of the renal epithelium. This process may take place in the kidney, but is continued in the bladder. Litmus paper, as an indicator of the true acidity of the urine, was unreliable in about 25 per cent. of the cases examined. The degree of acidity of urine, as measured in terms of its hydrogen ion concentration, showed in the author's cases a constant relation to its power to set free formaldehyde. The higher the acidity, the greater was this power. The requisite amount of acidity, which is not great, is present in the majority of normal urines, and can be secured in almost all cases by the use of boric acid or sodium acid phosphate. The author disagrees with the statements of Burnam and L'Esperance that only 50 to 60 per cent. of individuals break up urotropin. Examination of 213 specimens from fifty individuals showed that only in the urine of one case was formaldehyde never found.

3. **Intestinal Obstruction in Acute Appendicitis.**—D. Cheever points out that no more frequent and fatal complication of acute appendicitis exists than that comprising the various types of postoperative intestinal stasis. These may be assigned roughly to two main groups: First, those due to failure of peristalsis, resulting in intestinal paresis, distention, and stasis of the fecal current; and second, those due to mechanical obstruction resulting usually from kinks, twists, adhesions, or bands. The most familiar examples of the first group are the cases of paralysis associated with peritonitis, causing a toxemia acting either after absorption or locally on the neuromuscular mechanism of the intestine; the paralysis due to trauma, seen in the course of long abdominal operations involving manipulation and exposure; and that due to mesenteric thrombosis. Many of these cases are relieved spontaneously or by appropriate nonoperative measures, but not a few require interference by enterostomy, as an emergency measure to provide drainage until peristalsis may be restored, and no more anxious and difficult decision confronts the surgeon than when to interfere. The cases of mechanical obstruction forming the second group are sharply marked etiologically, but if they occur early they are unfortunately difficult to separate from the paralytic cases. This does not refer to the late secondary cases of ileus occurring weeks, months, or years after the operation. Inasmuch as mechanical obstruction, once established, is rarely relieved except by operation, and since the mortality of such secondary interference, high enough anyway, is vastly increased by delay, it becomes imperative to make the diagnosis and proceed to the relief of these cases at the earliest possible moment. Since in appendicitis the area immediately adjacent represents the usual region of peritonitis with resulting possibilities of adhesions, it is natural that the terminal ileum should be the most frequent seat of mechanical obstruction due to this cause.

4. **Pituitary Extract in Surgical Shock.**—C. A. Hill states that the administration of pituitary extract eliminates to a great extent the danger of shock developing after surgical operations. His routine procedure is to give the drug before the patient leaves the table and usually before closure of the abdominal wound is made. Fifteen minims are given hypodermatically. This dose is repeated every three hours until four doses have been given. In a series of eight hundred abdominal operations in which pituitary extract was used, the author did not note the development of shock in any instance except in two or three cases in which a condition simulating "heart exhaustion" was noted. This was only transient, the patient responding to stimulation after the administration of pituitary extract was discontinued. Another point mentioned is the happy result noted by several investigators as well as the author regarding the elimination of gas from the alimentary tract. Pituitary extract has a marked effect upon the muscular coat of the intestine, increasing peristalsis and facilitating the passage of gas.

5. **Artificially Dried Casein.**—H. J. Bowditch has been able to save the casein that is usually discarded in the making of whey. He has found that the casein curd can be dried and made into stable, pure, and soluble or insoluble powder. This powder may be used to increase the accuracy of administration of casein. Cases are being fed by the author on the basis of exact casein percentage, just as with sugar and fat.

5. **Relation of Syphilis to Internal Medicine.**—By W. T. Longcope. (See MEDICAL RECORD, March 8, 1913, page 454.)

6. **Hypertrophy of the Prostate.**—J. H. Gleason notes that the recent work of Tandler and Zuckerkandl has substantially advanced one's knowledge of the anatomy and surgical pathology of the prostate. It has further changed one's ideas as to what actually takes place in the operation of prostatectomy and the anatomical regeneration therefrom. Most remarkable, however, is the fact that an hypertrophy of all parts of the prostate does not exist. Contrary to old beliefs, the middle lobe and portion toward the bladder are always affected. Remarkable also is the fact that the prostate can be only artificially enucleated from its anatomical capsule. The capsule in the surgical sense is formed of atrophied prostatic tissue, which has been compressed by the hypertrophied portion of the gland. The proper and early treatment of a patient suffering from prostatism is most essential. The catheter should never be used habitually, and if its use becomes necessary in relieving acute retention, then the most scrupulous asepsis should be observed. Experience has demonstrated that the benign prostate has a tendency also to assume cancerous degeneration under the irritating influence of prolonged catheterization and its resulting complications. The ideal time for operation is before toleration and infection, and should be performed as soon as the presence of sufficient residual urine indicates the progression of the disease. Prostatectomy is not an operation to be attempted by an inexperienced surgeon. If the veteran in judgment and technique is ever needed in surgical procedure, certainly then the operator of known quality and skill is required in the management of prostatectomies.

8. **Medical Experts.**—H. M. Friedman outlines the following method of solving the problem of medical experts. Since expert opinion is in fact judicial opinion, the power of expressing these opinions must be vested in individuals or commissions, judicial in nature, especially appointed for such purposes, either by an executive, as in the case of many judges, or by a judicial officer in each case as is done in the appointment of referees or masters in chancery. The functions of these officers are to take testimony in such matters as are considered too complicated for the juries or too cumbersome for the judges—in "numerous litigated items," as they say in legal verbiage. The findings of fact by these officers are submitted to the court who, though it cannot usually alter them, can reject them entirely as unsatisfactory and refer the matter to a new referee or master in chancery, as the case may be. Similarly, medical questions are "numerous litigated items," and their reference to a *referee in medicine* would make for a more thorough adjudication of the questions in controversy, and with much less opportunity for bias. Yet both sides could bring their talent before the referee, who, being familiar with the scientific matters in question, could give the opinions of the experts their proper weight. The findings of such a referee would also be submitted and received as facts to be considered with the other facts in the case. The absence of any apparent bias by this method would inspire confidence in all concerned, even though not resulting in bringing before a court such an array of talent as is brought when the usual method is pursued.

9. **Gastric Ulcer.**—J. C. Kennedy points out that it is almost impossible, at times, to distinguish duodenal from gastric ulcer. Pain, however, if there is pain, does not occur in duodenal ulcer until two or three hours after the patient has taken food. With an empty stomach the pain is usually increased. On the contrary, the pain is relieved by taking food—the so called "hunger pain" of duodenal ulcer of Mayo-Robson. The reason of this, it is supposed, is because the acid gastric secretion is neutralized before passing the pylorus; thus the irritation of the ulcer is prevented. Gastric ulcer often exists together with duodenal ulcer; in this case a positive diagnosis is almost impossible. Hematemesis is also rare; in duodenal ulcer melena is often present; the quantity of blood in the stools is, as a rule, scant; tenderness is near the right costal border and extends somewhat downward; jaundice is rare—its presence, however, is an indication that the papilla of Vater is invaded, or it may be due to accompanying duodenitis; perforation is more frequent than in gastric ulcer. Gastric ulcer must be differentiated from gastritis; in this the vomiting does not recur regularly after taking food; constant nausea is almost pathognomonic of this inflammatory condition. The tenderness here is diffuse, and not localized as in gastric ulcer. Absence of food with other appropriate treatment quickly relieves this inflammatory affection, as a rule, while in gastric ulcer often the symptoms persist, and, if temporarily relieved, will frequently recur. Hemorrhage from the gastrointestinal tract due to other causes must be differentiated from gastric ulcer. A sudden rupture of varicose veins in the stomach without ulcer might give rise to a profuse hematemesis. An enterorrhagia from a walking case of typhoid fever might give rise to a suspicion of gastric ulcer. The surgeon must, therefore, be careful and, so far as he is able, get other symptoms than hemorrhage in gastric ulcer. A distinction between gastric ulcer and gastric carcinoma is frequently made, but with a thickened chronic ulcer with perigastric adhesions the diagnosis is difficult. Gallstone colic and cholecystitis, both chronic and acute appendicitis, as well as chronic and acute pancreatitis, must be thought of in the differentiation.

2. **Vertigo.**—A. C. Reed states that in the child transient vertigo is often due to mechanical causes, but most commonly it is due to a middle-ear infection following the acute infectious fevers. It may also be due to anemia or malnutrition, and occasionally one must consider the pos-

sibility of brain abscess or cerebellar tumor. In early adult or middle life vertigo can most often be traced to a vascular or reflex source, such as some disorder of the digestive or genital organs, or to arterial or myocardial changes. Ocular disturbances causing vertigo are also fairly frequent at these ages, and, of course, mechanical or aural vertigos may occur. With increasing age the vascular and certain types of reflex vertigo become more common. The vertigos from reflex irritation are most commonly due to irritation in the digestive tract or the pelvis. In treating these a sharp purgative may be given, followed by stimulants and sedatives and such medicines as may affect favorably the trouble in the exciting organs. Neurotic vertigos are somewhat similar to the reflex ones. They are common in neurasthenia and in certain degrees of nervous and emotional stress. Barany says that the vertigo of neurasthenia is characterized by irregular nystagmus, differing from the quick return of labyrinthine vertigo. Palliative treatment is secondary to thorough and persistent attack on the fundamental neurotic condition. Vertigo from purely vascular conditions or derangements, such as congestion, arteriosclerosis, anemia, and other disturbances of the cerebral circulation, should be treated according to the vascular underlying condition. Toxic vertigo, as from alcohol or a nephritis, calls for a like management. Auditory vertigo may signify organic disease, and is due to disturbance of the function of the space sense of the eighth nerve. This may be due to slight causes, such as the sudden occlusion of the eustachian tube, deranging the pressure in the tympanic cavity. Of the two labyrinthine vertigo from organic disease is more serious. Operative interference is seldom required in purely vestibular vertigo, but rest and quiet in bed are the prime needs. The second or paralytic type of vestibular vertigo following vestibular irritation, can be treated by progressive graded movements to reeducate the spatial sense of orientation. Meniere's disease is a term used to cover various forms of auditory vertigo with tinnitus and is always due to labyrinthine disease. Charcot's plan of giving increasing doses of quinine to cinchonism is recommended in this type and salicylate of sodium is said to be a good substitute for quinine in such cases. Vertigo from the disturbance of the ocular arc is less frequent than reflex or aural vertigos, and correction of the refractive error gives relief. Mechanical vertigos, like sea-sickness, car-sickness, etc., calls for no special method of treatment. To relieve the symptom when the cause is not apparent, the author recommends a purgative, rest, some volatile stimulant, and for internal administration sodium bromide 20 grains, three times a day, is probably the most satisfactory. A mustard plaster on the back of the neck, the application of warmth to the extremities, counterirritation with a weak mustard bath or hot water bags outside of the blanket, and occasionally a slight cautery of the mastoid region may be useful.

4. **Laryngeal Tuberculosis.**—R. Levy notes that among the earliest symptoms of laryngeal involvement slight intermittent hoarseness occurs as a local expression of a general anemia, often unilateral and on the same side as an existing pulmonary tuberculosis. In such cases a sensitiveness and irritability of the pharynx is also a suggestive early symptom. Pain as a symptom has an uncertain significance. It is not absolutely distinctive of tuberculosis but an important distinctive point is found in its increase in the act of swallowing between meals or at the beginning of a meal. It is unquestionably a valuable symptom but not pathognomonic. A common error is to diagnose laryngeal paralysis from constant or intermittent hoarseness in pulmonary involvement. This is most often due to laryngitis sicca. Some aphonia following hemorrhage, while suggestive, may be due to other causes, but if it occurs before the pulmonary lesion has been detected it has some significance. It is also a mistake to infer laryngeal involvement from sudden hoarseness and aggravation of symptoms generally. Statistics show the disease most fatal in the female, which may be ascribed to the occurrence of pregnancy—a dangerous complication in any case of tuberculosis. As regards the effect on the voice a large proportion of voices can be restored to usefulness even in cases in which extensive destruction of one vocal band has occurred. The least hopeful cases are those with extensive fibroid hypertrophy of the arytenoids and interarytenoid space associated with perichondritis invading the cricoarytenoid articulation. As regards treatment the consensus of modern opinion supports the following: (1) Treatment by means of rest to vocal organs in conjunction with rest and general hygienic measures. (2) Local measures, modification of surgical procedures. Among these the use of the galvanocautery seems to have at the present time the most advocates. (3) The relief of pain by injection or section of the superior laryngeal nerve. (4) The use of tuberculin.

5. **Thrombophlebitis of External Iliac Vein.**—M. Leale discusses the subject of the symptomatology and diagnosis of thrombophlebitis of the external iliac vein and reports a case complicating typhoid fever. Thrombophlebitis of any vein is usually the result of a bacteriemia or toxemia from surgical infections or infectious disease but it may occur from any cause increasing the coagulability of the blood. In most cases a constriction of the vessel wall is needed, but anything lowering the vitality of the blood-vessels or markedly retarding the velocity of the blood-stream in the vein tends to favor it. The symptomatology may be very clear or may be very obscure and in examining for lesions in the external iliac veins the anatomical conditions must be kept in mind. The further above Poupart's ligament the thrombophlebitis occurs, the greater the difficulty. When it is merely an extension of the process in the femoral the case is different but when it begins within the abdomen an early diagnosis is very important and difficult. The early symptoms are a dull ache or more or less sharp localized pain and a sudden rise in the pulse rate which is usually small, followed later by fever, and it may be twenty-four hours after the first symptoms before anything can be found by palpation. In a day or two there is likely to be edema of the leg or near the site of the thrombus but this may be a late symptom. The edema of cardiac or renal disease shows more pitting on pressure. The occurrence of distention or regional or general tympanites should be noted. In other acute abdominal conditions the pain is frequently not so localized, and there is a marked fall in the blood-pressure in acute abdominal conditions and a steady aggravation of the symptoms. The rigidity of overlying muscles is not so marked in iliac thrombosis. The brief rapidity of the pulse is a hopeful symptom but it does not usually last very long. Blood examinations in the early stages of thrombosis do not show as marked leucocytosis or as great a rise in polynuclears as in the acute stages of most infections. Careful examinations of the blood may afford valuable evidence. In considering the prognosis one must bear in mind that the thrombus may not completely occlude the vein at the start but may do so later, and then the prognosis will depend on how rapidly the collateral circulation is formed or whether or not the thrombus is absorbed. The possibility of an embolus is also to be considered. The condition of the patient is important. The better the circulation of the blood and the condition of the heart and blood-vessels, the more rapid the disappearance of the symptoms. In the case reported the complication occurred in an otherwise uneventful convalescence from typhoid fever.

6. **Skin Grafting without Dressings.**—J. Wiener reports a case in which he tried skin-grafting without dress-

ings. The conditions were unfavorable and yet the results were such that he has used this method of open grafting even in desperate cases and almost always with success. He has found it inadvisable to apply a wet dressing, even a bland one, until at least two weeks have elapsed. The grafts are cut as thin as possible and applied in the usual manner. Suppurating sinuses in the grafted area are packed with iodoform gauze. These packings are changed, as often as they become saturated with the discharge, without disturbing any of the grafts. The grafts can be placed within a half inch of a discharging sinus. During the first day or two crusts of inspissated serum form between the different grafts; these crusts should not be disturbed. For seven or eight days, or even longer, no dressing of any kind is applied. Usually after the first day or two, the grafts have already become firmly adherent and have a healthy pink color. After seven or eight days a weak ichthyol ointment is applied over the entire grafted area. Under this dressing the crusts that have formed between the grafts drop off, and in a short time the area assumes a normal appearance.

1. Physiology of Open-Air Treatment.—L. Hill is convinced that the whole of the effect of open-air treatment is due to the movement, temperature, and moisture of the air and has nothing to do with its chemical properties. Conformity to a better mode of life will enormously increase the health and happiness of everybody. Modern life in tending to put people into confined places, heated by convectors, with perfectly made windows and no draughts, is diminishing the metabolism, vigor, health, and happiness of everybody, quite apart from causing tuberculosis. Man cannot go straight into these artificial conditions when he has been for a million years living an outdoor life, facing every element, wind, cold, and rain. One should compromise and arrange matters so that the individual may get open-air exercise and exposure to wind and weather.

2. "Colds in the Head."—L. Hill and F. F. Muecke using a mirror and speculum have found that the mucous membrane flushes and swells, becoming turgid with blood and tissue lymph and covered with a thick secretion, when the subjects are confined in a warm moist atmosphere—*e.g.* 80° F. At the same time the airway is narrowed and even choked up in those who have a deflected septum. After passing from the warm to a cold atmosphere one finds that the mucous membrane quickly becomes paler owing to constriction of the blood-vessels, but still remains swollen with tissue lymph, as is shown by its appearance and by the fact that it pits deeply when touched with a probe. The altered conditions seem to be such as may increase the liability to infection. In a warm crowded room the swollen mucous membrane of the nose of an individual, covered, as it is, with thick secretion, will be massively infected with bacteria explosively sprayed out by the other occupants who sneeze, cough, and speak in the room. On passing out into the cold, misty, outside air the blood-vessels constrict, and at the same time the nose is chilled by the greater conduction of heat, due to the cold particles of water in the inspired air. The defensive mechanisms of the blood, the immunizing properties of the plasma, the cleansing action of the ciliated epithelium, and phagocytic action of the white corpuscles are diminished by the low temperature, while the pathogenic bacteria find a suitable nidus for their growth in the secretion and tissue-lymph of the swollen mucous membrane. The immunity to "colds" of those who live an open-air life is well known. Massive infection does not occur, and so long as they are exposed to the cold outside air the mucous membrane, like the skin, remains pale and taut, moistened with a scanty secretion. One can lessen the liability to such infection by keeping the air of rooms and crowded meeting places cool and moving. A fan set to whirl the air in an experimental chamber will keep the nose paler and drier and the airway patent even when the air is heated to 100° dry and 83° F. wet bulb. Keeping the air in motion in crowded rooms by means of fans will not only keep the mucous membrane in better state, but also diminish the massiveness of the direct infection from mouth to mouth or nose to nose. Warm, dry air flushes the mucous membrane with blood, but produces less swelling and secretion than warm, moist air does. While convection heat, *e.g.* from an anthracite stove, flushes and swells the nasal mucous membrane, radiant heat, *e.g.* from a modern gas fire causes sweating from the skin and does not affect the nose. The cause of the headache and stuffiness felt in rooms heated by steam pipes, stoves, and hot air is due to the swelling of the mucous membrane of the nose and its air sinuses. The change from convected heat to radiant heat relieves the stuffy feelings, and at the same time causes the skin to become moist and the nose to return to the normal "out-of-door" appearance.

3. Symmetrical Cortical Necrosis of the Kidneys in Puerperal Eclampsia.—R. Jardine and H. M. Kennedy report three cases of this condition, in which suppression of urine was a pronounced symptom. An almost constant feature of fatal cases of eclampsia is focal necrosis in various organs of the body, but chiefly in the liver, and these are frequently associated with capillary thrombosis. In the author's three cases to the naked eye there appeared to be focal necrosis in the liver. Capillary thrombosis, however, was *not* apparent, and, in fact, in one—the earliest case——there was great dilatation and congestion of capillaries in the foci. The cause of the necrosis in the kidneys is the same as that which causes necrosis in the liver, and the thrombosis in the smaller cortical renal arteries is secondary to the necrosis of the renal cells In discussing the cause of the necrosis, the authors fall back upon the explanation that it is the deleterious influences on the cells produced by the eclamptic toxin, whatever it may really be.

4. Alimentary Toxemia.—W. E. Dixon believes that alimentary toxemia is poisoning produced not by "toxins," the term being used in its strict sense, but by relatively simple chemical substances. These poisons originate as a result of digestion or putrefaction of food, chiefly of the proteins. It is true that under certain conditions a kind of toxemia may be induced from carbohydrate metabolism; for example, in certain conditions of the bowel an excess of lactic acid may be found leading to an excess of ammonium salts in the urine and some four or five times the normal excretion of calcium; the result may be calcium starvation, of which one symptom is probably joint trouble. When the protein molecule is broken down by the action of acids, alkalies, or by digestive ferments, amino-acids are ultimately produced, and it is in this form that proteins are absorbed, and it is known that the administration of the final cleavage products of an artificial sterile pancreatic digestion will serve to preserve nitrogenous equilibrium in

an animal, as well as the administration of intact proteins. These amino-acids, of which a considerable number are known and which vary in kind with the proteins from which they are formed, are then non-poisonous substances and do not give rise to evil results in the animal body. Under the influence of putrefactive organisms these amino-acids may, however, be slightly altered in composition and become toxic.

5. **Chronic Intestinal Stasis.**—C. H. Fagge does not regard as inflammatory the bands localized to the terminal ileum with the appendix free and normal to the naked eye, always passing in the same direction as those which pass down and inwards to the ascending colon, and limited to one aspect of the intestinal circumference. He would even go so far as to regard as non-inflammatory some bands in which the appendix was involved. One has only to examine carefuly several of these bands to realize that they are quite unlike in appearance ordinary inflammatory adhesions. These bands and kinks produce pathological states, as evidenced by abdominal pain, tenderness, loss of weight, tone, and activity; flatulence, constipation, etc. Stasis is generally due primarily to a pathological condition of the lower ileum, evolutionary in origin, and in well-marked cases surgical treatment is required.

7. **Secondary Polycythemia in Cardio-Pulmonary Cases.**—F. Parkes Weber asks whether polycythemia is a good or a bad sign in cardiac cases. In a former paper he answered this question as follows: "Just as hypertrophy of the walls of the heart is useful in so far as it compensates for mechanical defects in the valvular apparatus, so also is polycythemia useful in so far as it compensates for difficulties in the proper oxygenation of the blood and tissues of the body; but just as in cardiac valvular disease great hypertrophy of the heart indicates some grave defect in the valvular mechanism, so also an extreme increase in the number of erythrocytes in the blood points to there being great impairment of the normal process of oxygenation of the body." With the cardiopulmonary cases, however, the prognostic significance of the polycythemia is somewhat different, or rather the outlook is exceedingly grave at the stage of the disease when cyanosis and a great degree of polycythemia become striking clinical features.

7. The Interneuronic Synapse in Disease. B. Henry Shaw.

1. **Intussusception.**—H. S. Souttar pictures the symptomatology of acute intussusception in infants as follows: The child is usually well nourished and in perfect health. The sudden onset of this severe condition in a fat and healthy baby is most characteristic. As a rule the condition starts with a severe and sudden abdominal pain, coming on in acute attacks with intervals often of complete relief. The child may vomit, but never to any great extent. Tenesmus is a marked feature, the child straining incessantly, but only passing a little blood and slime. At first a motion or two may be passed, but after this there is absolute obstruction, and no trace of bile will be found on the napkin. This sign, which was first pointed out by Barnard, is almost infallible, and should in every case be part of a routine examination. The blood and mucus are exuded from the intussusception in sufficient quantity to soon clear the lower bowel of its contents, in view of the violent peristalsis which is occurring. On examining the child in a typical case the abdomen will be fairly lax unless the child is actively straining. In the course of the colon a tumor may be felt. It has very definite characteristics: It is in the region of the transverse or descending colon. It gradually shifts its position, advancing along the colon and increasing in extent. It is sausage-shaped and of horseshoe form, the concavity being towards the center of the abdomen. Manipulation causes it to contract and become hard. This hardening is accompanied by an attack of pain and an increase in the tenesmus. The characteristic feature is that, although the tumor may not be very tender, and manipulation may cause no instant pain, the pain rapidly follows and continues long after manipulation has ceased. The apex may be felt by the rectum. The presence of this tumor is the essential sign of intussusception. In studying cases of intussusception occurring after the first year of life one is at once struck by three features in which they contrast forcibly with cases in infants. In 70 per cent. of the cases a definite cause can be discovered; they tend to be chronic; the symptoms are irregular. In an extensive series of cases (Eliot and Corscaden) the following were found to be direct causes: (1.) Tumors were found in 40 per cent. Of these 24 per cent. were innocent. (2.) Ulcers were found in 14 per cent., and were due to typhoid fever, dysentery, and tuberculosis. (3.) Meckel's diverticulum (inverted) was the cause in 12 per cent.—a very remarkable number considering the comparative rarity of this abnormality. (4.) Trauma, such as a blow or a violent strain, was a definite cause in a few cases. More or less acute attacks occur, with intervals during which the patient is free from any acute symptom and only complains of general poor health. The attacks become more frequent and severe as time goes on, but they may go on over a period of from a month to a year. Pain is always a prominent feature. Vomiting occurs in two forms, which should be carefully differentiated. With the pain there is the bilious vomit due to dragging on the mesentery. Apart from pain, and in the later stages, there occurs the dark vomit of intestinal obstruction, with all the grave characteristics of that condition. Wasting and anemia are always marked, and frequently lead to a false diagnosis, such as tuberculosis, peritonitis, or carcinoma. Either constipation or diarrhea may be present. The former is more usual in enteric intussusceptions; the latter occurs in colic cases, and is accompanied by the passage of blood and mucus. A tumor is to be felt in the abdomen in most, if not all, of the cases.

2. **Transverse Colostomy.**—L. McGavin reports a series of cases in which a colostomy was performed. Of these 20 were done by the transverse and 6 by the iliac method. Of the former 3 were done for non-malignant and 17 for malignant conditions. Of the non-malignant 1 died of strangulation at three months, and 1 of phthisis at two years from operation, the third is alive and well to-day. Of the malignant cases 5 are alive to-day, 1 at three years, 1 at two years, 2 at eighteen months, and 1 at a year from the time of operation; and in all of these this method of colostomy has justified the opinion the author has formed of it, as it has also done in all cases in which the patients lived sufficiently long to allow of an honest judgment being formed. The transverse colostomy has many advantages and few objections. (1) There is good sphincter control. (2) There is firm support for a belt and plug. (3) There is freedom from prolapse. (4) There is greater accessibility both for cleansing and for defecation. (5) There is good spur formation. (6) The artificial anus is removed to a distance from the site of the growth in the rectum.

3. **Urachal Fistula.**—J. Elmsly Mitchell states that in urachal fistula, from which a certain amount of urine escapes upon attempts at micturition, any of the following

conditions may be observed: (1) A button-like papillary projection at the umbilicus with an orifice at its summit, through which a probe may be passed; (2) the urine may escape at several points of a hernial protrusion, covered externally by mucous membrane; (3) the orifice may be a mere deficiency in the linea alba. The abnormality may be said to be one of degree, the greatest deformity being fissure of the bladder, in which condition the allantois has failed to close completely inside the abdomen, so as to form the urinary bladder, and the lateral borders of the latter are adherent to the sides of the cleft, while the anterior wall is entirely absent. Again, the cleft may be confined to the upper part of the bladder, which presents itself as a red protrusion just beneath the umbilicus, the parts below being perfect. Whichever condition exists, there is a greater or less amount of discomfort and danger.

7. **The Interneuronic Synapse in Disease.**—B. H. Shaw believes that the cell-exhaustion theory does not satisfactorily explain the pathology of acute delirium. For purposes of comparison the author examined the records of 17 cases of insanity occurring after surgical operation, in which the important factor producing the alienation was exhaustion—physical and mental—plus the slight shock of the operating perhaps, and contrasted them with 25 cases of insanity immediately supervening in sudden and violent mental shock. It is pointed out that the type of insanity resulting from severe shock is decidedly different from that produced when exhaustion is the important etiological factor. As a result of sudden and severe mental shock, the tendency is to acute delirium, and when prolonged exhaustion enters into the causation the tendency is to depression. The greater the shock the more is the tendency towards delirium. The tendency in acute delirium is either towards rapid recovery or death. Whatever be the nature of the nerve current, the cell has apparently the power of releasing energy on the reception of a stimulus corresponding in degree to the intensity of that stimulus. The balance of evidence appears to be in favor of the nerve impulse being a physical process, and resistance to the passage of the nerve impulse is principally met with at the interneuronic synaptic membranes and finer terminal arborizations. The author has noticed that great susceptibility to the action of strychnine exists in hysteria, relatively small doses causing most unpleasant sensations, such as tachycardia and much mental uneasiness. Might not this indicate, he asks, that in hysteria the neuronic trouble is synaptic—that there is normally in this affection too little interneuronic resistance, resulting in a constant leakage of current, so to speak, outside the area to which it is limited in the normal individual?

## Berliner klinische Wochenschrift.

*April 28, 1913.*

**Infection and Digestion.**—Meyer states that even the ancients recognized "close relationship between digestion and infection, as shown for example through the fact that in fever a patient requires no nourishment. This fallacious interpretation was long ago exposed and has become replaced by another set of facts which show that digestion can cause or increase a fever which is not as a rule dependent on infection but which may in certain cases be due to or associated with some infectious process. For example, an infant may be attacked with some mild, obscure infectious process, such as furunculosis or colipyelitis. In such cases food may determine some derangement of the gastroenteric tract, most frequently diarrhea. The younger the individual the greater the tendency to diarrhea, because the instability of the intestine varies directly with the youth of the subject. In adults some infections also express themselves as a gastrointestinal crisis. The influenzal infection, for example, may manifest itself so decidedly by vomiting and diarrhea that authors write of a gastroenteric type of grip. It can be shown in all such cases that the diet of the patient has predisposed to digestive crises. Tests of the stomach in such cases also show diminished HCl in the gastric juice, diminished motility, and diminished capacity for resorption, so that the stomach is unable to handle food which in healthy equilibrium caused no disorders. We can only suppose that the infectious malady cripples the stomach and that certain types of food then cause a crisis.

**Diplomellituria.**—Stern implies by this term the coexistence or alternation of diabetic and non-diabetic glycosuria in the same subject. He has notes of over fifty such cases made during the past nine years. He insists that the two conditions (even if bound up in some common anomaly of metabolism) do not represent stages of one process but distinct pathologic states. A differential diagnostic parallel is given, from which may be gleaned that non-diabetic glycosuria may usually be connected with some antecedent condition, and disappears when this is removed; that the amount of urinary sugar is always small; that the bulk of the urine is not increased; that diabetic diet exerts little or no influence and that Gerhardt's reaction is invariably negative. Diabetic glycosuria is by contrast of unknown source, is eminently chronic, is usually of much higher degree, and is accompanied by polyuria. Gerhardt's reaction may be positive. The author apparently sees nothing in common between the two conditions, i.e., no basic carbohydrate intolerance, so that the coexistence is purely coincidence.

**Abderhalden's Hematological Studies and the Internal Secretions.**—Münzer discusses the relationship between Abderhalden's diagnostic reactions for pregnancy and tumors on the one hand and the pathology of internal secretions on the other. Naturally the alien albumin from the placenta and tumors may have something in common with the disordered secretions of glands of internal secretion. These substances may not, like those first mentioned, be split up by enzymes in the blood. Rather they themselves represent cleavage products of a more or less alien and toxic character. Fauser has recently sought to show that such products are able to produce psychoses, notably thyreopsychoses, dementia precox and luetic psychoses. In dementia precox cleavage products from the genital glands are accused. In metaluetic psychosis some unknown component of this sort may be unearthed in time. The parathyroid is suspected in connection with convulsive affections as well as the myasthenic states. It is time that these patients were treated with pluriglandular extracts

## Münchener medizinische Wochenschrift.

*April 29, 1913.*

**Complement Fixation Reaction in Congenital Idiocy.**—Froesch first gives an account of the Wassermann tests in idiocy. The percentage has usually been small, 1 or 2 per cent. in unselected material, although exceptionally it has been high—15 and even 30 per cent. The author's experience has been very unfavorable as but one patient in 102 gave a positive reaction. However, in about one-half of all cases there was exhibition of hemolysis. The author therefore prepared an artificial lipoid mixture in order to compare this test in idiots and controls. The inhibition in the Wassermann test clearly had no bearing on the presence or absence of syphilis. The reaction is in no wise specific for syphilis or any other affection but seems to indicate some breaking down of the central nervous system. In time the reaction may be shown to figure in bringing about Wassermann's reaction.

**Fatal Peritonitis Following the Use of a Laminaria Tent.**—Hussy reports a case from von Herff's clinic,

after stating that the use of these articles is very popular among the laity. In the United States their familiar use has much diminished, at least as far as the physician's endorsement is concerned. The victim was aged 45 and had begun to be irregular in her menses. This, however, was not imputed to an advancing menopause but to a combination of myomatous uterus with impending abortion. After ergot and a tamponade had accomplished nothing the house physician (Basel, Woman's Hospital) introduced a laminaria tent. Soon afterwards a chill followed by fever set in. The woman's face was pale and anxious. Hypogastrium tender. Uterus unevenly enlarged. Diagnosis, myomatous uterus, beginning peritonitis. There was a suspicion that the swelling tent had caused perforation. An exploratory laparotomy revealed a purulent peritonitis. The uterus and adnexa were removed, but patient soon perished from generalized peritonitis. The rationale of the infection was fairly clear. The initial tamponade no doubt paved the way and as a result of dilatation with the tent the offending germs ascended into the tubes and escaped into the peritoneal cavity. Schridde and others have shown how easily this mechanism operates and how laminaria tents contribute to the production of peritonitis. Naturally this sequela is not of universal occurrence. In fact not a few regard the use of tents as safer than metal dilators plus general narcosis.

**The X-Rays in Ovariogenous Affections.**—Hirsch champions the doctrine that not only at the climacteric but at any period in woman's life in which the ovaries are at fault, the Röntgen rays, through their destructive action upon the latter, are able to cure these ills. In 20 cases of amenorrhea with myoma the average dose was 81 x, and in 18 cases of amenorrhea with fibrosis the figure was 40 x as befits the fact that in the latter series the menopause was at hand. The main contention is the fact that through diffuse radiation as much as 1000 x are used up at a session. The economy of dose secured by the author is the result of special technique, of the type devised by Professor Klein for irradiation in cancer of the uterus, ovaries and mammæ. A special apparatus is utilized and the rays are concentrated on the so-called battle zone.

## Deutsche medizinische Wochenschrift.

*April* 24, 1913.

**The Bacterial Causation of Erythema Multiforme.**—Saisawa of Kitasato's laboratory, Tokio, believes that he has discovered that which has generally been supposed to exist. No doubt the prevalent view has been that a number of germs can call forth the same clinical picture, and several were long ago accused in this respect. The author shares this opinion and only claims that he has proved the existence of one such bacillary cause. It is of course plain that not all infectious germs can exceptionally give rise to the picture of erythema multiforme, else we should see it frequently in measles, scarlatina, etc. The author's case was seen in connection with preventive typhoid vaccination in a Japanese regiment. While getting ready to vaccinate the members the required tests excluded the patient under consideration, who was found to be febrile and was at once isolated. The picture was one of erythema multiforme, but the symptoms, at first mild, began to grow much more severe than usual. The lesions on the face became confluent, with great swelling. New crops appeared and some pus formed. There were no marked gastroenteric symptoms, although some round worms were expelled. There was acute cardiac dilatation which required digitalis and strophanthus. A special bacillus was found in the blood and urine. There were present phenomena of acute nephritis, and for some days the outlook for the patient was not encouraging. The author resists the temptation to call the disease influenza, which is known to be accompanied at times by erythema multiforme. The germ isolated by the author bears some relation to that described by Sabrazes. Thus far he has been unable to cultivate it, but other tests show a resemblance to the influenza bacillus.

**Action of Thorium-X on the Blood Cells.**—Arneth concludes a serial article on this subject as follows: When thorium-X is incorporated into the organism a very variable intensity of action is manifested on the leucocytes and erythrocytes. While in leukemia the number of leucocytes diminishes there is no corresponding improvement in the composition of the blood. Some months after injection of thorium-X, certain delayed changes may appear and the blood once more becomes approximately normal. The general impression is that blood studies have not been sufficiently carried out, with especial regard to counts, and that thus far we are unable to dose the remedy properly.

**Apocynum as a Heart Tonic.**—Textbooks many years old describe the root of ordinary milkweed, otherwise apocynum or Canadian hemp, as containing one or more glucosides which act in a manner similar to digitalis preparations upon the heart and kidneys. However, the same principle is also a drastic cathartic which naturally interferes with the other activities. Allard, however, treats the subject as relatively new and has been testing a new glucoside of apocynum which has been placed on the market under a proprietary name. The substance in animal tests behaves much like digitoxin. It also appears to possess a sedative and hypnotic action. In regard to the purgative activity of the old glucoside it is only mentioned that "in some cases diarrhea is caused" which may unfit it for administration *per os*. The remedy is unfortunately unsuited for hypodermic use, so that the intravenous method would seem to be that of choice. There does not appear to be any need of such a remedy as digitalis can do all that apocynum can and do it better and with less trouble. In supposititious cases in which digitalis is unsatisfactory it could be tested.

---

**Umbilical Concretions.**—Herzenberg gives a short but monographic account of this very rare find. He excludes from consideration all foreign bodies which have merely lodged temporarily in the fossa, without coincident change in the soft parts. The true concrements have the following genesis: at the outset the navel has a peculiar configuration, which favors the arrest in loco of shreds of clothing, hairs, dirt, etc. The second factor is the presence of some tenacious secretion from the sebaceous glands which acts as a cement. Upon this for a nucleus more sebum and epithelial débris are deposited until a conglomerate has formed. The presence of lime salts makes the latter a sort of tophus which has received the name of umbilical stone. Having attained a sort of natural limit of growth the concrement now begins to act as an irritant foreign body, setting up an inflammatory reaction which may involve a large area and simulate a tumor. Infection may readily occur with production of a phlegmon, the discharge from which contains in addition to pus crystals of cholesterin, fat drops and phosphates. As a rule from one to two months are required for the formation of one of these inflammatory tumors, this interval ending with suppuration. Given a phlegmon of the umbilical region, the presence in the discharge of phosphates points at once to the presence of one of these umbilical concrements. In the absence of phosphates in the discharge we have to think of the possibility of dermoid cysts, umbilical adenoma and even of actinomycosis. The author advises that in cases of alleged umbilical dermoid we should search for the presence of a concrement.—*Deutsche medizinische Wochenschrift.*

## Insurance Medicine.

**The Life Insurance Company as a Force in the Movement for Physical Welfare.**—In an article under this title, in the *Popular Science Monthly* for April, 1913, Eugene Lyman Fisk, Medical Director, Postal Life Insurance Company, shows why it is worth while for life insurance companies to engage actively in health-conservation work, and how it can be carried on by them to the best advantage. He summarizes the reasons as follows: (1) The machinery is at hand. (2) It can be utilized without loss, and with probable gain to both company and policyholder. (3) the nature and extent of the life insurance business imposes a public obligation to exercise this power for the welfare of the people. The medical and scientific staff of a life insurance company is trained in the consideration of disease-tendencies, rather than active diseased conditions; therefore, the influence of living-habits, and the significance of physical disabilities and abnormalities and especially of personal and family history, upon large masses of insured lives, form the body of the rapidly developing science of medical selection. By combining this intrinsic knowledge with the readily available extrinsic data of personal hygiene, the medical officers of a life insurance company are especially equipped to guide their policyholders toward safe and sane living-habits. Experience also shows that the policyholder will listen to the advice of his life insurance office on such matters, as he discerns the practical business motive that prompts it, however much there may be of normal genuine interest in human betterment. There are 25,000,000 old-line policyholders who pay annually to 250 companies. Every policyholder is in touch with at least two other individuals, thereby affording seventy-five million points of contact with the public, and constantly open channels of communication, through which educational material may be transmitted by these companies. Reduction of mortality-rate by health-conservation, means lowering of premiums paid by policyholders, and a saving, over and above the cost of carrying on the work, of $5,000,000 annually, in the United States, besides an annual saving of approximately 10,000 lives. Fisk gives the methods employed by his company to carry on health-conservation work. A Health Bureau was established in 1909, and has issued many publications, such as periodical bulletins to policyholders, dealing with such subjects as the causation of degenerative affections of the heart, blood-vessels, and kidneys; affections of the nose, throat and lungs, with preventive measures; dental and oral hygiene; drug addiction; physiological effects of alcohol and tobacco; causation and prevention of many infectious diseases; diet-hints; summer and winter hygiene, etc. Thousands of monographs have been distributed among educational centres. But probably, the most important benefit to the policyholder, has been through the system of free, annual medical examinations for the detection of disease or disease-tendencies at the earliest possible moment. Although less than 10 per cent. of the policyholders have availed themselves of this privilege, the results more than justify the company's action. Forty per cent. of the risks examined, were found impaired, and of these, 44 per cent. were absolutely unaware of their impairment, especially of the degenerative affections found at middle life, showing the need for such a system. Thus far, only three out of 250 companies operating in this country are active in health-conservation work. Fisk says the pressure of public opinion is needed to set in motion this vast machinery for lifting the burdens of humanity.

**Accident Insurance for Government Employees.**—A bill providing compensation for employees of the Federal Government suffering injuries or occupational diseases in the course of their employment, was introduced in the Senate on April 12, 1913, by Mr. Kern of Indiana. This bill has been drawn after careful investigation by the American Association for Labor Legislation and is to supplant the present law, which has been in force since May 30, 1908. As the law now stands, only one-third of the 350,000 federal employees are benefited, no relief is granted for incapacity lasting less than fifteen days, no provision is made for medical treatment, and the most liberal benefit grants only one year's wages even for total blindness, life-long disability, or death. Solicitor Charles Earl, for the Department of Commerce and Labor, reported recently that during the past three years, government employees suffered 21,000 serious accidents, 670 of which were fatal, but in only one-third of these cases did the injured workman or his dependents receive any compensation, because under the present law the remaining two-thirds of Uncle Sam's employees are unprovided for.

The Kern bill remedies the weaknesses of the old bill by including all civilian employees of the Government, reducing the waiting time from fifteen days to three, and granting a liberal scale of compensation during the entire period of disability. It also provides for the prevention of accidents and occupational diseases in navy yards and government workshops, and allows compensation for occupational diseases such as lead poisoning. A commission of three is provided to administer the law. Senator Kern points out that his bill will remedy the present mistakes for all time, and relieve the embarrassment and time-consuming special legislation at present required. The Kern bill will merely extend the compensation principle already adopted by the Government and eighteen individual States. The authors of this bill declare that when it is passed by Congress, the United States will approach more nearly the standard of the model employer, and America will have at least one compensation law up to the standard set by England, Switzerland, and Germany.

**Child Insurance Limit.**—The Court of Appeals at Albany has sustained the decision that a child between the age of seven and eight years cannot lawfully be insured for more than $168, as provided by the State insurance laws. This decision has been upheld in order to prevent neglect or actual maltreatment of young children by those responsible for them, for the purpose of obtaining pecuniary benefit out of the child's death. As the number of policies on a single life could not be limited, the result could only be effected by limiting the total amount of insurance on a child's life.

**The American Association of Medical Examiners** will hold its annual meeting on June 16, at 10 o'clock A. M., at the Hotel Radisson, Minneapolis, Minn. All physicians interested in insurance work are cordially invited to be present. Dr. Frank W. Foxworthy of Indianapolis is the president of the Association, and Dr. G. Strohbach, Miami Building, Cincinnati, secretary.

# Book Reviews.

Investigations on Epidemic Infantile Paralysis. Report from the State Medical Institute of Sweden to the Fifteenth International Congress on Hygiene and Demography, Washington, 1912. Published by the State Medical Institute. Stockholm: Nordiska Bokhandeln, 1912.

The first epidemics of poliomyelitis occurred in Sweden, which was also the seat of the awful ravages of this disease in 1905 and 1911. It is quite natural that the most valuable clinical and epidemiological studies of infantile paralysis should emanate from that country. The present volume comprises the results of the experimental and epidemiological studies of this disease, which were stimulated by the widespread epidemic of 1911. The experimental portion begins with an elaborate study of the presence of the virus of infantile paralysis in human beings, by C. Kling, A. Pettersson, and W. Wernstedt. Among other valuable results, it was found that the secretion from the mucous membranes of the mouth and intestine of persons who have recovered has had the power of infecting monkeys still several months, in one case 204 days, after the outset of the illness, giving rise to an experimental poliomyelitis with fatal issue. Another important study is that of the clinical picture of experimental poliomyelitis in monkeys, as well as the study of the histological changes in the spinal cord of monkeys affected by poliomyelitis. The second part of the volume details certain epidemiological experiences gathered from the epidemic of 1911. One of the most striking of these experiences was the observation that the disease tended to spare those communities that had suffered most during the previous epidemic of 1905, and that the areas invaded during the later epidemic were to a certain extent on the periphery of the areas affected during the earlier epidemic. In other words, the disease spread somewhat in the form of a ringworm patch. It is pointed out that in its epidemiological aspects poliomyelitis bears a close resemblance to epidemic meningitis.

Forensic Medicine and Toxicology. By C. O. Hawthorne, M.D., Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow; Lecturer on Forensic Medicine in the London School of Medicine for Women; Physician to the Northwest London and Royal Waterloo Hospitals. Third Edition. Price $1.75 net. New York: Longmans, Green, & Co.; London: Edward Arnold, 1912.

This book presents in a brief and succinct manner the subjects of legal medicine and toxicology. It is based upon the larger works, but by the omission of cases it is able to furnish to the medical student and practitioner all that he is required to know on the above subjects. The book is well written and may be recommended without reserve as one of the best of the smaller volumes on forensic medicine and toxicology.

A Practical Treatise on Fractures and Dislocations. By Lewis A. Stimson, B.A., M.D., LL.D. (Yalen); Professor of Surgery in Cornell University Medical College, New York; Consulting Surgeon to New York, Bellevue, St. John's, and Christ Hospitals; Corresponding Member of the Société de Chirurgie of Paris. Seventh Edition, revised and enlarged. With 459 illustrations and 39 plates in monotint. Price, $5.00 net. New York and Philadelphia: Lea & Febiger, 1912.

The name Stimson has become synonomous with the standard of authority on fractures. With the recent developments in the open treatment of fractures, the time is quite opportune for the appearance of a new edition of this work. This, the seventh edition, has been revised and enlarged, and contains among its additions the discussion of the operative treatment of recent fractures, a section on the treatment of old dislocations, three new sections on certain fractures of the small bones of the hand and foot, and one section on fracture of the external tuberosity of the femus. To the many excellent illustrations of the former editions, one hundred new ones have been added. There are in all 459 illustrations and 39 superb plates representing chiefly the *x*-ray appearances of fractures and dislocations. As regards the open treatment of fractures the opinion of the author may be quoted: "To sum it up, direct fixation is very rarely necessary; when it is made convenient by an existing wound it should be temporary, by the use of an absorbable suture or of one that can be easily removed after a few days. Pins reaching to the exterior are also objectionable because of the difficulty of keeping their track aseptic; the infection may spread to the fracture. . . . It is, I think, unquestionable that the results of the general use of M. Lane's method would not materially differ from those heretofore obtained by the use of other fixation methods, and it is, therefore, by the results of these other methods, and not by Mr. Lane's, that the propriety of open fixation is to be judged. . . . I still feel that the advantages claimed are inadequate to offset the discomforts and risks of the operation, and that in most hands even those advantages would not be obtained; that external splints would still be needed for fixation, and that suppuration followed by delay in union or death would frequently occur." A copy of "Stimson's Fractures" should be in the library of every practitioner.

A Manual of Immunity for Students and Practitioners. By Elizabeth T. Fraser, M.D. (Glas.), Late Assistant Bacteriologist, Glasgow Royal Infirmary; Beit Research Fellow. Price $1.60. New York: The Macmillan Company, 1912.

During the past twenty years the science of immunity has been the most living branch of medicine and to-day it occupies a position of the highest importance. In both diagnosis and treatment the general practitioner is constantly coming into contact with the immunologist (a better word than "immunizator") and it is essential that he acquire more or less knowledge of the fundamental facts of this science. To this end a large number of books, some good, many poor, have appeared within the past few years. This volume is one of the best of these books. Extremely elemental in character, it tells the story in "words of one syllable" so that all may understand. It can be recommended as a well prepared and easily negotiated first step toward familiarity with the great problems of immunity.

Insomnia. Its Causes and Treatment. By Sir James Sawyer, of London, Doctor of Medicine of the University; Fellow of the Royal College of Physicians, lately Lumleian Lecturer; Fellow of the Society of Antiquaries, of Edinburgh, Fellow of the Royal Society of Birmingham; Consulting Physician to The Queen's Hospital; once Professor of Pathology, then of Therapeutics, lastly of Medicine, in the Medical School; Knight Bachelor. Second edition with many revisions and additions. Price 2s. 6d. net. Birmingham: Cornish Bros., 1912.

The first edition of this little monograph was really a revision of chapters on the causes and treatment of insomnia appearing in the author's book entitled "Contributions to Practical Medicine." The present edition, therefore, represents a second revision. It is based on material of practice, and embodies notes on the prevention, analytical diagnosis, and medicinal and hygienic treatment of what is truly stated as a complex malady. An index has been introduced into this edition to facilitate reference, and other additions in the text are to be noted, derived from the author's later experience. Some further revision could be made to bring the book well up to date. It retains the colloquial style of the original clinical lecture of 1878, and much of the first part (on causation) could well be omitted as immaterial. The author cautions the reader not to begin treatment for insomnia until he knows that it is really present; and secondly, if present, to ascertain its nature as regards etiology. For its curative treatment he relies on medicinal, hygienic, educational, and physiological agencies. Each case requires separate study as to causes, idiosyncrasies, habits of life and of body and "temperaments." Many useful hints may be obtained from a perusal of this little book.

Medizinisch - Chemisches Laboratoriums - Hilfsbuch. Von Dr. Med. et Phil. Ludwig Pincussohn. Mit 75 Figuren und einer Spektraltafel. Price Marks 13.50. Leipzig: F. C. W. Vogel, 1912.

The field of the laboratory worker in medicine has become so extensive and demands so much more than a smattering of many branches of scientific knowledge that there is every reason to suppose that the present volume will find numerous appreciative readers. All of the chemical and physical procedures likely to be required by medical investigators are described more or less fully, and the attempt has been made to add to the completeness of the book by including sections on the examination of the blood, on bacteriology, complement fixation, etc. These, of course, are so brief as to have little value and in the opinion of the reviewer might better have been omitted. Even in other portions of the book the descriptions of the methods could advantageously have been made more detailed, since but few references to original articles are supplied. This is the only criticism that seems justified, for the amount of information here brought together is truly enormous and the volume is just what is needed for quick reference when there is no time or opportunity for consulting the encyclopedic works of Abderhalden, Neuberg, and Oppenheimer. A very useful set of tables on the most varied subjects fills the last 100 pages of the book.

Second Report of the Government Bureau of Microbiology, dealing with work performed during the years 1910 and 1911. Sidney, N.S.W.; William Applegate Gullick, Government Printer, 1912.

This is a quarto volume of 244 pages and represents to good advantage the really enormous amount of work which is being done by the government in Sidney. The reports cover a large part of the field of bacteriology in its relations to man, animals and plants. The most interesting are articles on the biological characters of the *B. typhosus* and a comparative study of some strains of diphtheria and diphtheroid bacilli.

Stuttering and Lisping. By E. W. Scripture, Ph.D. (Leipzig), M.D. (Munich); Associate in Psychiatry, Columbia University; Director of the Research Laboratory of Neurology, Vanderbilt Clinic; Formerly Assistant Professor of Experimental Psychology, Yale University. Price, $1.50 net. New York: The Macmillan Company, 1912.

An extremely valuable text-book upon a sadly neglected theme is provided by this volume, which is from the pen of one who has given years of special study to the subject of speech defects. These he has approached along two different paths: that of psychology and that of practical medicine. The present volume is meant for both the teacher and the physician. The importance of its subject matter to the former may be realized if one is told that from one to two per cent. of school children are stutterers. The recognition of the cause of stuttering may be a difficult matter in some cases. Nevertheless, the therapy of nearly all cases is not so difficult that it is beyond the scope of the general practitioner. The latter will find this volume a clear and concise presentation of the subject. Dr. Scripture advances the view that stuttering is a disease marked by the following cardinal symptoms: (1) psychic hypertonicity and spasms of the muscles of speech; (2) anxiety (embarrassment or fear); (3) fixation of these conditions by habit, and (4) the existence of these symptoms only in the presence of other persons. Lisping is of quite a different nature. It includes several different speech disorders, whose characteristics lie essentially in defects of enunciation. The author distinguishes four different types: negligent lisping, organic lisping, neurotic lisping, and cluttering. The neurotic type is described here for the first time. The various graphic methods employed in the study of speech defects are described. Illustrated cases are given. The book closes with an elaborate series of exercises that will prove valuable in the treatment of stuttering and lisping.

A Treatise on Pellagra for the General Practitioner. By Edward Jenner Wood, S.B., M.D., Chairman of the Pellagra Commission, North Carolina Board of Health, etc. Price $4.00. New York and London: D. Appleton and Company, 1912.

Appearing in this country as a disease either entirely new or hitherto unrecognized, pellagra has excited a great deal of attention and investigation, the fruits of which have been exhaustively detailed in this book. The author pointedly disagrees with the older theory of the etiology of the disease that it is a grain intoxication, resulting from the ingestion of spoiled corn. Following Sambon he is inclined to believe that it is a parasitic, insect-borne disease, transmitted by a Simulium, a species of biting fly. He is confirmed in this belief by its analogy to other protozoal infections, its peculiar seasonal incidence and by the fact that wherever pellagra has been proved to have originated, there this fly has been found. He takes issue with those who make a diagnosis of "pellagra-sine-pellagra" that is pellagra without the characteristic eruption, on the ground that in the present state of our knowledge in this country, such a diagnosis is unsafe. In his experience the disease has never occurred without presenting, at some stage, the typical erythema. The book is written in a clear, convincing manner and the author is evidently thoroughly acquainted with his subject. It is attractively published and can be recommended to all interested in the subject.

Bacteria. By Dr. Max Schottelius. Second Edition. Translated by Staff-Surgeon Herbert Geoghegan, R.N. Henry Frowde, Oxford University Press. Price $3.50. London. 1912.

Written in popular language, with a style that is attractively easy and at times delightfully dramatic, this little book contains a semi-scientific discourse upon the general subject of bacteriology. The second edition has been somewhat enlarged and the chapters on Immunity and Protozoa have been practically rewritten. Almost wholly neglecting the technical details concerning individual bacteria, the author rather devotes his time to the hygienic aspect of the subject. The matter is presented in a form that is easily understood and the volume can be recommended as suitable for the instruction of the layman who seeks bacteriological information. The work is very attractively published.

Diseases of Children. A Practical Treatise on Diagnosis and Treatment for the Use of Students and Practitioners of Medicine. By Benjamin Knox Rachford, Professor of Diseases of Children, Ohio-Miami Medical College, Department of Medicine of the University of Cincinnati; Pediatrician to the Cincinnati Hospital, Good Samaritan Hospital and Jewish Hospital; Ex-President of the American Pediatric Society, and Member of the Association of American Physicians. New York and London: D. Appleton and Company, 1912.

In the large number of text books on the diseases of children there is noted a certain uniformity of method and presentation. A standard has been created, and apparently every new work on this subject aims to follow this more or less closely. The different works vary chiefly in the emphasis which they place upon pathology, diagnosis, and treatment. In the present volume the author devotes most attention to diagnosis and treatment. He has written a sound and practical exposition of modern pediatric science, based upon a wide practical experience. The work is up to date in its inclusion of the newer classifications and the newer methods of diagnosis and treatment. Thus the author reports favorable results from the use of casein milk, misnamed "albumin" milk, in the treatment of gastro-intestinal indigestion. It may be questioned whether the preparation of this, as described by the author, is strictly in accordance with the method advised by Finkelstein. The author boils the milk first instead of heating it to 100° Fahr. The book is well written, and the numerous illustrations help to elucidate the text. The typography, paper, and binding leave nothing to be desired. The volume may be recommended to the student and practitioner.

Travaux de Chirurgie Anatomo-Clinique. Par Henri Hartmann, Professeur à la Faculté de Médécine; Chirurgien de l'Hôpital Bichat; Membre de la Société de Chirurgie. Avec la collaboration de B. Cuneo et Paul Lecène, Professeurs agrégés, Chirurgiens des Hôpitaux; Kuss, Prosecteur à la Faculté; Delamare, V. Henry et Lebreton, anciens internes des hôpitaux. Quatrième série. Voies Urinaires, avec 132 figures. Price 15 francs. Paris: G. Steinheil, 1913.

This is the fourth volume of Hartmann's Clinical Surgery and is devoted to surgery of the prostate and urinary organs. Small sections on anatomy, operative technique, pathology, and case reports are accredited to his collaborators. In the first chapter is tabulated his operations and death rate. The list is interesting and instructive since it is the summing up of an experience of many years. The number of general surgical operations reported is 1787 with 113 deaths, 6.3 per cent. That presumably simple operation of internal urethrotomy was followed by death in 7 of 290 cases, 2.4 per cent. Following an analysis of these statistics, much space is given to prostatic surgery. He prefers the suprapubic route of enucleation and selected that approach in the majority of his later cases. The technique described differs in no material steps from that of Fuller and Guiteras. The results reported are less brilliant than those of American surgeons and the number of secondary operations reported causes one to think that the author's foresight was by no means so good as his hindsight. Moreover, the frequency of complications and sequelæ noted in his case reports do not compare favorably with those of our countrymen. This cannot be justly attributed to lack of operative skill but probably is due to the fact that several cases were operated twenty years ago when prostatic surgery was primitive, together with the tendency of his compatriots to present themselves for relief only when in deplorable condition. Insufficient discussion is accorded to postoperative treatment and only here and there does the reader glean a helpful hint. The chapters on renal surgery are clear and distinct. His description of surgical conditions of the kidney and the operative technique of their treatment is especially good. Likewise, the immediate and ultimate results are good. Several rare and unusual clinical conditions are described in detail; one of a vesical myoma completely filling the bladder and protruding through the ulcerated abdominal wall. Another is a gangrene of the bladder following a caustic injection into the viscus. The author's eminence, ability and rich experience gives such weight to his words that the interest of every genitourinary surgeon cannot fail to be awakened.

An Atlas of the Differential Diagnosis of the Diseases of the Nervous Systems: Analytical and Semeiological Neurological Charts. By Henry Hun, M.D., Professor of the Diseases of the Nervous System in the Albany Medical College. Price $4.00. Troy, N. Y.: The Southworth Company, 1913.

This is a new departure among books on the diagnosis of nervous diseases. We have had the symptoms of different diseases contrasted in parallel columns in tabular form, and collections of charts and diagrams of the nervous system. These have all been of assistance in diagnosis at times. But here is presented a key by which even the student and the general practitioner may work out his own neurological salvation (if he has some intelligent knowledge of the subject), in apparently a comparatively easy manner. Diseases of the nervous system are divided in the book into groups, the members of which bear a relationship to one another. This relationship is definite and constantly crops out in the use of the charts. The same disease appears in many charts, and cross references by numbers are placed in the text to facilitate reference. On one side of each chart is an important symptom; on the other a list of all the diseases in which this symptom occurs. Between the two a series of tests are inserted which constitutes the examination of the patient. All the important diagnostic symptoms of nervous diseases are thus treated. The usual methods employed by clinical teachers of neurology are utilized. The clinical physiology and pathology of nervous diseases are given with the differential diagnosis. Technical terms are defined. The index is very complete and embraces nearly every clinical neurological term. The book is divided into three parts, Semeiology, Diagnosis, and Localization. There are twenty-two charts, and thirty-three figures. Electrical examination and examination of the cerebrospinal fluid are included in part one. The book is of special service in diagnosis in organic neurology.

The Surgical Diseases of Children. By William Francis Campbell, A.B., M.D., Professor of Anatomy, Long Island College Hospital; Surgeon in Chief, Trinity Hospital; Attending Surgeon, Methodist Episcopal Hospital; Consulting Surgeon, Coney Island, Swedish, and Jamaica Hospitals; and Le Grand Kerr, M.D., Attending Pediatrist to the Methodist Episcopal, Williamsburgh, Bushwick, and Swedish Hospitals; Consulting Pediatrist to the Industrial Home for Children and the Rockaway Beach Hospital. New York and London: D. Appleton & Company, 1912.

This is a handsome volume of 693 pages representing the combined authorship of the surgeon and pediatrist. Judging by the number of volumes upon the surgery of childhood that have appeared during the past few years, there is apparently a demand for a book of this kind. There can be no question that the pediatrist should have a voice in the management of children that come under the care of the surgeon. This is particularly necessary in such cases as empyema and surgical tuberculosis, in which the postoperative dietetic and hygienic care is an important factor in the final outcome. At the same time the surgeon can be of distinct service to the pediatrist not only in providing the technical skill in the presence of cases requiring operative treatment, but also in suggesting the proper line of non-operative treatment in cases that are usually classified as surgical. It must also be borne in mind that the work of the orthopedic surgeon is almost entirely among children, and most of these are first brought to the general practitioner or children's specialist. Both of the latter should be well informed, not only in the latest methods of surgical diagnosis but also in the methods of surgical treatment, so that they can recognize a surgical case when one presents itself, and can call in the proper surgical assistance when this is indicated. In short, the general practitioner, the pediatrist, and the surgeon should be well informed not only in their own respective field of work but also in that of the others. The value of a volume of this kind depends upon the degree to which it recognizes the places at which the three domains overlap one another. Judged by this criterion the present volume admirably answers its purpose. In discussing the subject of appendicitis in children the essentially surgical character of this disorder is emphasized, and the treatment is considered under the two heads, preoperative and operative. It is to be regretted that this volume touches but lightly or not at all on certain subjects that ought to be discussed in detail. Thus only a half page is devoted to the subject of hypertrophied tonsils, no mention being made of the methods and technique of their removal, of the relative merits of tonsillectomy and tonsillotomy, of the contraindications to either operation, of the local and systemic complications that frequently follow operation, and of the preoperative and postoperative treatment of the patient. The same scant attention is paid to the subject of adenoids, which is dismissed in a brief discussion of one page. Only one-third of a page is devoted to the subject of the mechanical and operative treatment of the deformities of infantile paralysis, a subject that has acquired considerable importance within recent years. The chapter on lumbar puncture is well written and well illustrated, but the authors ignore the most modern method of introducing antitoxic sera into the subarachnoid space, namely, by means of allowing the sera to flow in by gravity rather than by injecting them with a syringe. No mention is made of the manometric measurement of the pressure of the cerebrospinal fluid, nor of the therapeutic possibilities of lumbar puncture in the case of uremia, hydrocephalus, etc. Many sections of this work, as for instance those on the plastic surgery of the palate, and of such congenital deformities as hypospadias, etc., are well written. Would it be amiss to ask why so many of the excellent illustrations are borrowed from other authors? Surely it is possible to obtain a good photograph of a case of hydrocephalus without resorting to this convenient expedient. Of course credit is given in every instance to the source of the illustration, but it is irritating to one who is fortunate enough to be within easy access to a large number of textbooks to come across the same illustrations in two or more works. It is questionable whether most of the cuts that adorn a medical work are of real practical value to the reader. In spite of its shortcomings this work cannot fail to be of service to the general practitioner and surgeon. It bears the imprint of originality and good taste and reflects views that are generally sound and practical.

The Labyrinth. An Aid to the Study of Inflammations of the Internal Ear. By Alfred Braun, M.D. (New York) and Isidore Friesner, M.D. (New York). With Fifty Figures in the Text and Thirty-four Halftones on Thirty-two Plates. Price $4.00 net. New York: Rebman Company, 1913.

The bibliography of the labyrinth comprises works and articles that have appeared mostly within the past decade. It is only, however, the past three or four years that have witnessed the epoch-making contributions of Alexander, Barany, Bartels, Brünings, Neumann, and Ruttin. The study of the labyrinth represents one of the most fascinating subjects in medical science, a subject teeming with problems in anatomy, histology, physiology, otology and neurology. A great deal has been added to the knowledge of this obscure recess of the cranium, but it is still upon the frontier, awaiting further discoveries and developments. It is a pleasure therefore to welcome the present volume by Braun and Friesner, which is a complete monograph, including all that is known at the present regarding the labyrinth and its diseases. The book is divided into five chapters which deal with the subject as follows: Anatomy, physiology, methods of examination, pathology, symptoms of labyrinthitis, and treatment of labyrinthitis. The authors describe the anatomy and physiology of the labyrinth in a masterly manner. The illustrations here, as in other parts of the work, are superb in their artistic execution and in the clearness with which they supplement the text. The methods of examination are described in great detail with the aid of many diagrams. This is a section of the work that should appeal to the neurologist. There are discussed the caloric test, which has attained its greatest elaboration at the hands of Barany; the galvanic test; the fistula test, and reaction movements. In discussing the pathology of the internal ear, the authors adopt the practical classification of labyrinthitis into the circumscribed and the diffuse forms. It is noted that the most common of the acute middle-ear diseases which cause labyrinthitis is that due to scarlatina, while of the chronic middle-ear conditions cholesteatoma is responsible for most of the labyrinthine affections. The chapters on the symptoms and treatment of labyrinthitis are exceptionally well written. The authors lay down as a broad, general rule that in no case of circumscribed labyrinthitis should the internal ear be operated upon. The various operations, including Hinsberg's and Richards' operations, the Jansen operation, and the Jansen-Neumann operation are described in great detail with the aid of many excellent halftone illustrations. It is stated that the most conservative of the operations is that of Hinsberg. In concluding what can be regarded only as a fragmentary review of this important subject one may state without reserve that the authors have acquitted their task well, and have made a substantial contribution to medical literature.

## MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

*Stated Meeting, Held March 17, 1913.*

THE PRESIDENT, DR. REYNOLD WEBB WILCOX, IN THE CHAIR.

**The Clinical Evidence of Lymphuria.**—Dr. HEINRICH STERN presented this paper, which was read by Dr. A. Ernest Gallant. (See page 967.)

**Colon Bacillus Infection of the Kidney.**—Dr. WINFIELD AYRES read this paper. (See page 968.)

**Hydronephrosis.**—Dr. A. ERNEST GALLANT read this paper. He explained that by hydronephrosis, or what more properly was termed uronephrosis, was meant urinary retention within the renal pelvis, or pelvis and ureter, caused by something which had obstructed the outflow of urine into the bladder. The origin of the obstruction might be congenital or acquired. The latter form of obstruction, by far the more frequent, might be due to such causes as strictures, neoplasms, adhesions, bands, blood, etc., but was much more commonly caused by kinks, calculi, or concretions. The obstruction might be located at any point where the lumen of the tract could be bent, narrowed, or plugged between the renal calices and the ureterovesical junction. *Ren mobile,* or displaced kidney, was by far the most frequent source of urinary obstruction, and was second only to calculus in the production of pathological conditions in the kidney. The range of the mobility varied very greatly, though the severity of the resulting suffering bore no relation to the degree of mobility or the distance to which the kidney had prolapsed. A case well illustrating what a prolapsed kidney might lead to was that of a female patient, 59 years old, whom he first saw on February 19. For two or three weeks she had been suffering from intermittent attacks of nausea, vomiting, and intense pain (Dietl's crises). The pain, starting just under the right breast, at times extended down to the hip and radiated through to the back. At first sitting up seemed to afford some relief, but more recently had aggravated the pain, and she could lie only on her right side. She had lost some 30 pounds in weight, had much distress after eating, and was constipated. At first her skin was slightly jaundiced; the conjunctiva decidedly so. Physical examination showed the abdominal wall to be very lax; epigastrium sunken; hypogastrium markedly prominent; lower border (greater curvature) of the stomach nearly down to the symphysis; lesser curvature three inches below the ensiform. The right kidney, which was three times the normal size, and very sensitive, had prolapsed to such an extent that the lower pole pointed forward and lay just above the umbilicus, while the upper pole pointed backward and could be palpated in the loin; representing the so-called "pendulum" prolapse, in which, on account of its large size, the kidney could be but partially replaced. The point of greatest tenderness was over the situation of the gall bladder, which was not palpable. The liver was not enlarged or prolapsed. Diagnosis: Hypertrophied, displaced kidney, dragging on the common bile duct and ureter, and causing jaundice and uronephrosis. During the following two weeks, although the patient reclined in the elevated posture, the attacks recurred with increasing frequency. The report of the urinalysis, by Dr. Heitzmann, in conjunction with the clinical history, seemed to point most strongly to ureteral obstruction, probably associated with calculus. On March 6 the kidney was exposed through a lumbar incision and, after being freed from the very dense adhesions present, was delivered. The pelvis was opened and the ureter probed into the bladder without finding any stone, though there had evidently been kinking at the pelvoureteral junction which was released when the kidney was freed. On account of the condition of the kidney and the laceration of the pelvis, it was decided to remove the organ. After the removal of the kidney, but before suturing, while the fatty capsule was being palpated, it was found that the gall bladder was filled with stones, and after the lumbar dressing had been applied the patient was turned on her back and a vertical incision made at the outer side of the right rectus. The under surface of the liver and gall bladder seemed to be filled up with masses of enlarged glands, and in the removal of one of these glands for pathological examination the gall bladder was opened, allowing the escape of stones. It was rapidly sutured to the skin, and while this was being done the stones continued to come out. The kidney removed was presented. Among 411 cases of movable kidney Dr. Gallant had recognized obstructive hydronephrosis symptomatically in 126, or 30+ per cent. In one case there was sigmoid distortion of the ureter at its pelvic junction; in one, stricture of the pelvic portion of the ureter four years after hysterectomy, and in two cases a descending ureteral calculus was the source of typical ureteral colic; but such conditions were far outnumbered by the remittent attacks of hydronephrosis caused by movable kidney and which were relieved by loosening the clothing and lying down. By this means the kinking was corrected. Hence the pain, nausea, and vomiting (Dietl's crises) ceased, the swelling in the lumbar region subsided, and the woman passed large quantities of urine. Then there would be freedom from symptoms until the kidney again dropped down low enough to cause ureteral kinking and urinary obstruction. During twenty years' observation of this class of cases it had always been his practice to place the patient in bed with the foot of the bed elevated some 10 or 12 inches, and by this means had secured prompt relief, provided that the kidney could be wholly or in part replaced. Whenever this postural treatment had failed he had found some complication present, such as gall stones, stricture, calculi, blood, etc. By thus elevating the pelvis we (1) relieved the symptoms, (2) established the differential diagnosis, and (3) ascertained the correct treatment required, whether medicinal, mechanical, or operative. As to the prognosis, temporary obstruction of the ureter might cause but little if any damage to the kidney tissues, but frequently repeated intermittent obstruction gave rise to dilatation and distortion of the ureter, and renal pelvis, resulting in an interstitial nephritis. The research work of Edwin Beer and others had shown that continuous obstruction beyond 21 days caused irreparable damage to the kidney. The treatment, advised by the speaker consisted in (1) postural, diagnostic replacement, (2) mechanical support by a corset constructed on proper principles, in order to keep in position all the prolapsed organs; (3) appropriate operative measures for the removal of pelvic disease when present; (4) such rest cure methods and medicinal means as will restore the normal health balance. In cases of replaceable prolapsed kidney nothing was to be gained by suturing the kidney (nephropexy) because, as had been pointed out by Glenard, we very seldom met with movable kidney causing obstruction in which there was not an associated dilatation or prolapse of the stomach and colon; a condition far more detrimental to health, though the symptoms were not so acute. The paper was concluded with the report of an illustrative case in which there was a prolapsed right kidney, with remittent hydronephrosis, and ptosis and dilatation of the stomach. For these conditions the patient had worn the special corset advised by Dr. Gallant, and he said that she had learned by painful experience that the attacks would recur if she were careless in putting the corset on or did not keep it in good repair.

**Bilateral Nephrolithiasis.**—Dr. OLIVER C. SMITH of Hartford, Conn., in this paper, said that while the operation of vesical lithotomy was among the earliest successful surgical procedures, operations for calculi of the kidney and ureter were of comparatively recent date. Before the use of the cystoscope, ureteral catheterization, urinary separation, and skiagraphy, operations upon the kidney were undertakings of great risk, but now the cooperative efforts of those working in different lines of scientific investigation and diagnostic technique had placed the surgery of the renal tract upon a scientific basis, and reduced the hazards to a minimum. The frequency of simultaneous occurrence of stones in both kidneys had been variously estimated at from 50 per cent. by Lagueu, to a much smaller proportion, but the possibility of this condition should always be borne in mind by the surgeon when planning operation for renal calculus. The importance of skiagraphing both kidneys and the entire renal tract, and of determining the patency of each ureter and the functional activity of each kidney, was paramount. Although authorities differed as to the possibility of securing skiagraphs of certain types of renal calculi (notably those composed of uric acid and cystine), the skiagraph taken and interpreted by an expert was the most accurate factor in the present-day diagnosis of urinary calculi. In order to determine the comparative density and resulting radiographic shadow, Dr. Smith's associate, Dr. Arthur C. Heublein, had made radiographs of a number of renal calculi of various composition. (At the conclusion of the paper lantern slides of these were exhibited by Dr. Heublein.) From these, the speaker said, it would be seen that even the uric acid and cystine calculi furnished definite shadows, and while it was true that these radiographs were made of the stones after they had been removed, in a favorable subject, and with a modern apparatus, it was possible in a certain percenatge of cases to secure shadows of even these kinds of deposits. In our zeal to apply the

latest and most satisfying aids to diagnosis, we might at times be inclined to neglect the older but still valuable methods of rigid physical examination and painstaking, accurate microscopical search for urinary sediment. When it was considered that primary renal calculi were the result of inherent conditions, rendering both kidneys equally liable, it seemed strange, and was indeed most fortunate, that bilateral calculi were so comparatively infrequent. The dangers of bilateral were more than double those of unilateral calculi. Structural damage and infection might go on simultaneously in both kidneys, finally rendering operation upon either or both far more serious than that for a unilateral affection. Anuria, a condition supposed to be due to a reflex inhibiting excretion, was, unfortunately, prone to follow these operations. In bilateral renal calculi two problems confronted us: (1) Shall we operate at all, and, if so, on one or both kidneys, in the absence of moderate or urgent symptoms? (2) Shall we operate on both kidneys at one time? The greater number of operations had been performed on one kidney, the other being attacked later or not at all, in accordance with the developments following the first operation. While Kümmel, Watson, and others, advocated operating on both kidneys at one time, a frequent contraindication was the serious condition present; the added time, increased amount of anesthetic, and additional shock and hemorrhage had to be reckoned with. In two of his own cases the primary operations were done in severe emergency; in one instance the operation upon the second kidney was performed later, when the patient was in better condition. These cases improved markedly between the first and second operation. In the first, the second operation was called for some weeks later by an acute infection occurring in the unoperated kidney, and in the second an elective operation was done for a large stone, with infection, some weeks following nephrostomy and nephrolithotomy for pyonephrosis and nephrolithiasis. Dr. Smith then gave the details of the following cases: *Case I.*—Male, aged 24. Bilateral nephrolithiasis; pyelitis; nephrolithotomy. On June 29 an oxalate of lime stone, measuring 7 x 8 x 5 cm., and weighing 33 gm., was removed from the pelvis of the left kidney through the cortical incision; after which two stones of marble size and a number of sand-like stones were removed. At the end of six weeks the patient was apparently well, and returned to work. On September 8 he was seized with pain in the region of the right kidney, accompanied by chill, and followed by high temperature. The urine became scanty, and contained a quantity of pus. Five days later, through lumbar incision, the right kidney, which was much swollen, was exposed, and incised over the cortex, and 15 to 20 c.c. of pus liberated from the pelvis. Three stones were removed (two of marble size and one the size of a kernel of corn), and the patient made a good recovery. *Case II.*—Male, aged 45. Bilateral nephrolithiasis; pyelonephritis; nephrostomy. First operation on September 15; second operation December 5. Four weeks after the latter, patient left hospital and resumed work. *Case III.*—Female, aged 35. Calculus anuria following nephrectomy for calculus pyonephrosis; nephrolithiasis; calculus impacted in ureter; ureterolithotomy; recovery. *Case IV.*—Simulating bilateral renal or ureteral calculi. This patient was a college student who when 15 years old had an attack of appendicitis, for which the appendix was removed. Aside from urinary retention, requiring catheterization on two occasions, his recovery was uneventful. Three months later he was seized with severe pain on the left side of the abdomen, radiating from the kidney down the ureter to the testicle. Frequent hypodermics of morphine, supplemented with ether at the acme of the pains, were required for three days, when the attack suddenly ceased. For three years afterward similar attacks occurred at irregular intervals and at the most inopportune times. The pain was so agonizing that doctor and nurse were called in and remained with him practically throughout the paroxysms, which lasted from one to four days. He would apparently follow the progress of something down the ureter, speaking of a slipping sensation, and finally, after a prolonged exacerbation, would say "There, it has passed." The attack would then end, though it was quite likely to be resumed on the other side within a few hours. On one occasion a number of blood corpuscles were discovered in the urine, but never any crystals. The reaction of the urine was acid, the specific gravity usually high at the beginning of the attack, and the color darker than normal amber. It was never the pale color of hysteria. On two occasions ureteral catheters were passed to the pelves of the kidneys and twice a series of radiographs were made, with negative results. He consulted distinguished specialists in New York and Boston, each one in turn at first believing that the passage of bilateral calculi was the undoubted diagnosis, but each finally concluding that the condition must be a neurosis. During the three years when the attacks were the most frequent and severe the patient was attending a high school, and about the time of his graduation they became less frequent. He then entered Yale and passed through his four years there with but three attacks. In the two years which had elapsed since then he had only two attacks, though he still lived in fear of their repetition. In other respects his health was good. In Dr. Smith's series of seventeen operations for renal and ureteral calculi, 18 per cent. had been bilateral. In all the latter cases pain had at some time been present and there had been hematuria and pyuria in all. Renal epithelium and crystals had been less constant in the urine, while enlargement of the kidney had been detected only at the time of partial or complete obstruction in the ureter or renal pelvis. In the four operations in cases I and II the kidney had been incised, rather than the pelvis. The presence of pyonephrosis, as well as pyelitis, demanded this incision in two instances, and the necessity of exploring and draining the kidney, as well as the removal of stones from the calices, made it the operation of choice. He believed that it was often desirable to incise the pelvis when the radiograph showed stone in the pelvis only, and the kidney was not otherwise diseased. The anesthesia employed had been gas-oxygen-ether, either in sequence or the three merged to meet the immediate conditions. Drainage of the kidney was resorted to in all cases. If anuria threatened, the drains were temporarily removed, hot packs applied to the whole body, and hot fomentations over the kidneys, and diuretin given hypodermically. Among the speaker's conclusions were the following: It was probably better to operate on both kidneys at one time if the patient's condition warranted. This had to be determined during the course of the operation. The more seriously impaired kidney, or the one causing most severe and recent symptoms, should be operated upon first. Lithotomy should only follow thorough and exhaustive efforts to establish a correct diagnosis of the condition of each kidney. Operations of this kind should be largely confined to hospitals where all the modern aids to diagnosis were at command. Such methods as radiography, cystoscopy, ureteral catheterization, renal function tests, and chemical and microscopic examinations of urine called for generous cooperation on the part of a number of competent and well-equipped men. Without such scientific preliminary work these operations were likely to result in disappointment and disaster, while with it the operative mortality was encouragingly low and the ultimate results, measured in life and function, were in the great majority of cases most satisfactory.

Dr. Louis Heitzmann said he doubted the propriety of discussing Dr. Stern's paper, which was purely a theoretical one, in Dr. Stern's absence. The claim in it was more a theory of his than a proven fact, and under the circumstances, therefore, he preferred to say nothing more about it. The subject of Dr. Ayres' paper was, unfortunately, one about which too little was known. Yet the cases of colon bacillus infection of the kidney were not rare. Dr. Ayers was of the opinion that all cases of this character were of hematogenous origin; but while he himself was sure that in the great majority of instances this was (*a*) Right optic tract, left homonymous hemianopsia for the case, he believed that we did have some cases of ascending infection. It was not always easy to prove that a case was of the ascending variety; yet when the bladder symptoms preceded those of the kidney, and when inflammation in the bladder had lasted for some time before there was any trouble in the kidney, as could be determined by microscopical urine examination, some evidence was afforded of such an ascending infection. This did not necessarily start in the bladder, but might arise in the vagina or elsewhere. Dr. Smith's paper was certainly one of great interest. If all skiagraphs of the kidneys were as plain as those which had been shown this evening, there would never be any difficulty in diagnosing renal calculi. Unfortunately, however, the *x*-ray in many instances proved entirely unreliable. There might be no shadow at all, or if there was a shadow, it might be due to other causes. It was in cases of this kind that we had to resort to other means, and here, he believed, the microscope was of more value than anything else. Yet in these cases of Dr. Smith's, even if the skiagraphs had not been so plain, the indications were such as to give rise to the suspicion of the presence of calculi. When there were hematuria and pyuria, and we could exclude other causes, there was strong ground for supposing that calculi were present; wherever a ureteral catheterization could be made as in hospital cases this would aid in the diagnosis. The

functional tests, in his opinion, were of little value, and the phenolsulphonaphthalein test was decidedly unreliable. The examination of the specimen of urine sent him by Dr. Gallant indicated the presence of a mild interstitial nephritis, a condition proven by the kidney which the doctor showed. While by many it was not admitted, it was easy to diagnose the existence of such a nephritis by microscopical urinalysis, without the presence of casts in the urine.

Dr. Robert T. Morris said it made very little difference whether the colon bacillus infection came by way of the blood, the lymphatics, or by ascending infection. Usually, however, it originated from the blood. The thing to do was to relieve the patient, since the presence of the wandering colon bacillus in the body usually meant sepsis. Still, it was a fact that in many instances its presence in the kidney was a matter of little or no moment. Fortunately, we had at our command a good resource for this infection, provided it was used in the right way. The correct method of employing urotropin depended on one or two little refinements, and one of these was to give it in conjunction with sodium benzoate. We had a still better remedy in the new methylene citrate. In regard to kidney stone, there were some instances in which the calculi were nearly pure uric acid, giving no shadow. Now, whether the *x*-ray showed the presence of stone or not, when we found blood and pus coming from a kidney, there was something there which called for operation. If not stone, it might be tuberculosis, or even fatty degeneration, as in one case he had seen. As a rule, patients operated on made a good recovery, but occasionally even what seemed to be the most favorable cases terminated fatally. This it had been his melancholy experience to see only last week, when a lady who presented every appearance of perfect condition died suddenly from embolism three hours after the operation.

Dr. Joseph Friedman said that one of the reasons why renal calculus was not more often diagnosed by means of the *x*-ray was because of faulty technique. The intestinal tract of the patient should first be thoroughly cleared out. It was his practice to give a full dose of castor oil in the evening, and repeat it the next day. The patient should be placed on a liquid diet, though milk should be excluded, as this substance caused a shadow to appear in the colon. Then, about two hours before the radiograph was taken an enema should be administered. A good picture ought to give the outline of the kidney, but often this was not obtained. It was always best to confirm the diagnosis of kidney stone, and therefore a second radiograph should be taken three or four days later. If the shadows at first observed were then in the same position, we could feel that the diagnosis was assured.

Dr. Ayres, in closing, said that Dr. Smith had touched on phenolsulphonephthalein, and though he considered it the best test yet devised, there was much to be desired. He gave the history of two cases. The first was that of a man 79 years old. Absolute retention; phenol. test (given subcutaneously) was 7 per cent. the first hour and 8 per cent the second. It was decided to drain by permanent catheter until the kidneys were acting better, but, on account of hemorrhage developing, the bladder was opened and the prostate removed. Though the patient suffered somewhat from uremia, he finally pulled through and made a perfect recovery. In the second case, also prostatic hypertrophy, the phenolsulphonephthalein was given intravenously. 42 per cent. was returned in the first half-hour, and 27 per cent. in the second. The patient died from uremia ten days after operation. Dr. Ayres had had two cases in which the *x*-ray did not show the presence of renal calculus, but in which he was able to detect this by means of the wax-tipped catheter. In the diagnosis of this condition the laboratory aids should always confirm the clinical findings. He could not agree with Dr. Morris that sodium benzoate aided the action of urotropin, though he considered it a valuable urinary antiseptic. Cases in which it seemed to have the action of a help, he said, were probably those in which no formaldehyde was being thrown off and the antiseptic action was entirely due to the benzoate. He admitted that he had neglected to mention in his paper the possibility of ascending infection, but he considered it an extremely rare occurrence.

---

**Public Exhibition of Hypnotism Forbidden.**—The Italian Government has forbidden demonstrations of hypnotism and all kindred arts in theaters. This action has been taken in consequence of representations by the medical profession as to the deleterious effects of such exhibitions on weak-minded people.

## NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, Held April 17, 1913.*

The President, Dr. William M. Polk, in the Chair.

This meeting was arranged by the College of Physicians and Surgeons.

**Pneumonia from the Laboratory Point of View.**—Dr. Augustus B. Wadsworth read this paper. He said that the physician at the bedside of a pneumonia patient needed, first, broad conceptions embracing alike possibilities and probabilities of the infectious processes to which he was to minister, conceptions based on the results of accurate experimental study. He then needed sufficient clinical knowledge to recognize the significance, diagnostic and prognostic, of the various signs and manifestations of the disease, in order to interpret the individual symptom complex. The laboratory and the bedside, each in its sphere, the one as much as the other, were educationally essential to the attainment of modern standards in the conduct of pneumonia infection. The story of experimental pneumonia was a long one, but was interesting and most instructive. The study of pneumonia offered the widest scope, the greatest promise and the most insurmountable difficulties, and had proven as elusive as it had been alluring. The sudden onset, the more or less unique course, the sharp and peculiar termination by crisis, all suggested much to the student of immunity and serum therapy. The great menace of the disease to the public health and the futility of preventive measures and public sanitation served to stimulate every effort to solve the subtle problems of both cure and prevention. Seemingly barren of results, the results had nevertheless added much to their knowledge of the conditions, factors, and processes underlying and determining the development and course of the disease, and thus possessed a value none the less definite and practical if lacking in the spectacular. If the significance of laboratory study was to be fully appreciated pneumonia must be considered broadly as a conservative reaction of the animal organism to infection of the lung. Lobar pneumonia was a distinct disease; the lesion of the lung was characteristic as was also the symptom complex. In man the lobar lesion was a specific infection due to the pneumococcus, but in animals it had been incited experimentally by many pathogenic bacteria, by non-pathogenic species, and by chemical incitants. Similarly, the symptom complex, strikingly characteristic as it was of lobar pneumonia in man, was occasionally seen in erysipelas, and in the rabbit a pneumococcus bacteremia without lung infection often followed this course even to recovery by crisis. Lobar pneumonia, anatomically and symptomatically considered, was thus a specific disease incited by the pneumococcus only as it developed in man. But even in man certain conditions of animal susceptibility on the one hand and bacterial virulence on the other hand underlay the development of the disease. These conditions were now recognized through the study of experimental pneumonia. In very susceptible animals pneumonia was not incited by tracheal injection of the pneumococcus; but in resistant animals, as in the experiments of Gamaleia, of Tschistovitch, and of Meltzer on the dog, typical lesions were obtained. In his experiments characteristic lesions developed in the susceptible animal only when it had been practically immunized. A relative insusceptibility, possibly some degree of immunity, was therefore essential to the development of lobar pneumonia. This immunity man might possess normally, or since the pneumococcus was frequently associated with inflammatory processes in the upper respiratory tract he might acquire it during recovery from them. Bacterial virulence might be also just as important as animal susceptibility in determining the development of pneumonia. Washburn and Eyre, Longcope and Fox, and recently Dochez had studied the virulence of different strains of pneumococci. But when the virulence was raised experimentally in one animal it was lower for other species. It was therefore impossible to determine the virulence of the pneumococcus for man by testing it in laboratory animals. At the bedside there was ample evidence of the toxicity of the pneumococcus but in the laboratory no toxin had been found. Although the parasitism and the toxicity of the pneumococcus in infection might be recognized separately, these biological activities were closely related one to the other. They had been discussd at length because they were fundamental and essential if one was rightly to conceive the disease processes in all their relations. The growth of pneumococci under artificial cultivation was inhibited at a comparatively low temperature. Of 26

strains which he had studied none grew above 41.2 C and many ceased growing above 40.5 C. In the pneumonia patient the temperature of the circulating blood was one degree centigrade higher than that of the mucous membranes and the temperature of the liver and other organs higher than that of the blood. It was not difficult to conceive of pneumococcus growth in the tissues of the pneumonia patient being inhibited. However an elevation of body temperature alone might not be conservative but injurious, as Dr. Wadsworth had found by experimental study. The protective mechanism should be studied as it occurred spontaneously and as it was induced under experimental conditions, not in one animal but in several. Recovery could not be considered complete until the infectious agents of the disease were destroyed. This must take place either inside the body cells through phagocytosis, or outside the body cells by bacteriolysis. In different animals these processes varied greatly. As in diphtheria and in tetanus so also in pneumonia the neutralization of the bacterial poison was the dominant process determining recovery. The destruction of the bacteria was secondary whether it took place by lysis or by phagocytosis, whether it took place in a local wound in the surface of the body or in the issues throughout the body. Fundamentally it mattered little whether the bacterial poison was found only in the body tissues and could be easily neutralized there, or whether it was also found outside the body in culture and could be neutralized in the test tube.

Dr. Rufus Cole said that he was much interested in the conception of the pneumonia process, as described by Dr. Wadsworth. All those who had had much to do with pneumonia as seen at the bedside had become convinced that the main process was essentially a general intoxication. The difficulty had been to prove this. In a way, intoxication must be associated with all infections. The idea of the mechanical action of bacteria was long ago given up. The action of the bacteria on the body must be due directly to some chemical substance formed by the action of the bacteria, or to some peculiar physical changes brought about by the bacteria, of which at the present time they could have but little conception. Of the nature of these intoxicating substances in pneumonia, at present they know but little. Such toxins, produced by the bacteria, might be non-specific or specific. They knew that pneumococci produced acid, for instance, in culture media, and it was conceivable that the intoxication in pneumonia was closely associated with the production of acid in the body by pneumococci. Last year Dr. Peabody did quite extensive work to determine whether or not acidosis was present in pneumonia. While there was some evidence that there was an increased acid production in the body in pneumonia, yet there was no evidence that this played the main rôle. It had been found that the bodies of pneumococci, when allowed to undergo autolysis, were toxic, and the speaker said that he had also shown that the bodies of pneumococci, when dissolved in bile, were toxic. This toxic bile extract, when injected into animals, gave rise to the production of antitoxins. This was evidence that the substance was a true toxin. Of course, it was impossible to say at present whether the toxin did or did not play an important rôle in the symptoms as seen in patients. This toxin was quite different from the toxin described by Wadsworth, since it was held back by the Berkefeld filter, while the toxic substance described by Dr. Wadsworth was obtained by filtering the culture through such a filter. Dr. Wadsworth had not shown this to be a toxin when injected into animals and so, of course, had been unable to demonstrate directly the production of an antitoxin, but his experiment and evidence to show indirectly that the immune serum produced by the injection of this substance was antitoxic, seemed to be extremely clear and important. The fact that by such a serum the symptoms might be inhibited, while the bacteria still continued to grow in the body, spoke strongly for the antitoxic action of the serum. This observation furnished evidence against the point of view which might otherwise be suggested that the serum so obtained was an antibacterial serum, produced by the injection of free receptors contained in the filtrate, just as had been done in the production of immune sera to *B. choleræ* and *B. typhosis* and also to the pneumococcus. Dr. Wadsworth had approached the problem of pneumonia in a fundamental manner and had already obtained important results, and the speaker felt sure that his work continued along these lines would add much to our knowledge of this most important disease.

Dr. W. T. Longcope said that Dr. Wadsworth's paper emphasized two points of great interest. One was the susceptibility of the host to infection, the other the virulence of the infecting agent. Dr. Wadsworth, in the first part of his paper, had made some reference to the possibility that the onset of the infection of lobar pneumonia might be dependent upon a sensitization of the host to the pneumococcus. This conception has been brought forward by Friedberger and Vaughan, and Friedberger, particularly, had applied this idea to the rapid invasion of the lung by the pneumococcus in lobar pneumonia. Dr. Wadsworth's experiments concerning the method of producing a certain type of pneumococcus infection in rabbits, simulating lobar pneumonia, emphasized the point that the host must in some way be prepared before an infection with this particular course could take place. Partial sensitization of which he spoke might indeed represent in a way the sensitization of the animal, just as one by one or two injections of horse serum or egg albumin, rendered a rabbit susceptible to intoxication by that protein. Recent experiments by Austrian seem to point quite definitely to the fact that animals might be made susceptible to infection by the tubercle bacillus when they were given a preliminary injection of the protein from the tubercle bacillus. If, now, the onset of pneumonia were dependent upon the sensitization of the tissues of the respiratory tract to pneumococcus, one would expect that preceding an attack of pneumonia there would be a history of some respiratory infection. As a matter of fact, Dr. Meltzer, among others, called attention some time ago to the fact that such slight respiratory infection did very frequently precede the onset of lobar pneumonia, and that the disease did not develop suddenly. During the last few years this point had interested him very much, Dr. Longcope said, and he had made an effort to discover in all cases of lobar pneumonia that had come under his observation whether or not there was a pre-existing respiratory infection, and on careful questioning it could be determined that the vast majority of patients had had a "cold in the head," some respiratory infection, which was frequently termed grip or sore throat, within one, two, or three weeks before the onset of the lobar pneumonia. The cause of these infections could naturally not be determined, but it is interesting to observe that such mild infections were present. Certainly in combating such serious diseases as pneumonia lines of thought such as these suggested by Dr. Wadsworth were valuable in stimulating work which had as its object the prevention or the cure of the disease.

**An Unusual Cardiac Condition Simulating the Stokes-Adams Syndrome.**—Dr. Horatio B. Williams and Dr. Henry James reported this case. Dr. Williams said the patient had been under observation since July, 1912. He presented himself on account of increasing dizziness with attacks of faintness. His previous history was negative, except that he had been a very hard worker and had formerly used whiskey to excess. There was no history of syphilis and Wassermann reaction was negative. His pulse was uniformly slow, about 40 beats per minute. The electrocardiograms showed an entire absence of the wave P which corresponded to auricular activity in its usual position. There was no suggestion of auricular fibrillation. An inverted wave was constantly found one-fifth of a second after the beginning of ventricular action. The auricles had been found to contract co-ordinately with each beat of the ventricles by direct observation with *x*-rays and fluoroscope. It was believed that the beat of the heart originated in the ventricles and was transmitted backward to the auricles by way of the His bundle. The condition had been imitated in dogs by destruction of the region of the sinus node in the right auricle. Lately several observations had been made of this patient when his pulse ran about 60 beats per minute and at such times the electrocardiograms were of the usual type, the auricles beating before the ventricles. There was still a tendency to revert to the reversed mechanism.

Dr. T. Stuart Hart said that the case just reported illustrated very beautifully the object and value of the new graphic methods of studying the heart. For a long time, on account of the methods at their disposal, physicians had paid much attention to the endocardium, the condition of the valves and the pericardium. They wanted to know more about the myocardium, but they knew comparatively little in regard to it because the means of studying it were very limited. By these new methods, the polygram and the electrocardiogram, they were put in a position where they could observe in detail the functional workings of the myocardium. Working with these methods, Dr. Williams had been able to point out certain definite defects of conduction, irritability, and changes in the pace-maker in the case he had presented. Such

observations were not merely of academic interest, they were also of immediate help to the clinician. The study of these disorders of the fundamental properties of heart muscle were of great service in making a correct diagnosis, in formulating the prognosis, and in directing treatment. As evidence of this one need only to recall the aid which these methods had afforded in heart block, extrasystoles auricular fibrillation, and in directing the proper use of digitalis. Dr. Williams had described an entirely new clinical entity and had offered valuable experimental evidence to support his interpretation of this case. Hereafter, since Dr. Williams had shown the way, any of us ought to be able to make this diagnosis. Dr. Hart referred to a case of his own in which, like Dr. Williams' case, there had been a reversed rhythm; this, however, had been a case of paroxysmal tachycardia of ventricular origin. During the paroxysm the auricle responded to the ventricle, but only to every alternate beat, the other impulses starting in the ventricle being blocked. The attacks of unconsciousness in Dr. Williams' case were probably due to temprorary cerebral anemia; it was likely that the slow pulse of 40 was not alone the cause of this. One often saw a heart rate of 40 with no attacks of unconsciousness; in this case not only had the pulse been slow, but each of those 40 beats was inefficient, since in each the sequence of the contractions of the chambers of the heart was abnormal. Dr. Hart cited a case which he had seen in which "fainting attacks" came on with a heart rate of 200; these were extra systoles, and so although many in number were ineffectual in maintaining the circulation. To maintain a proper circulation not only should there be a sufficient number of beats, but in each the sequence of the contractions of the chambers of the heart should occur in the proper order.

**Prolonged Complete Heart Block Without Lesion of the Bundle of His.**—Dr. B. S. Oppenheimer and Dr. Horatio B. Williams presented this communication, in which it was stated that the electrocardiograms were obtained from an old hemiplegic patient who was known to have complete heart block from February 26, 1912, up to the day of his death, December 31, of the same year. During many months he had pronounced Cheyne-Stokes respiration. The interest in the case lay in the fact that there were frequent changes in the electrical complexes of the ventricular beat and correlated with this the fact that histological examination revealed no organic lesion to account for the block, in the auriculonodal junction, the node of Tawara, or the main stem and its branches. The nodal artery was sclerotic. The variations in the ventricular complexes were seen not only from one examination to the next, but often from beat to beat. The waves Q, R, S, T all showed variations. The auricular rate was strikingly reduced during the dyspneic period, being 41.49 beats per minute, as compared with the rate of 94.17 during apnea. The ventricular rate was only slightly reduced during dyspnea, being 0.46 beats per minute, as compared with 31.25 beats per minute. In other words, the vagus had still a marked chronotropic effect on the auricle and little if any on the ventricle. Two atropine tests were made during which the heart block was not relieved; and again, the auricular rate was decidedly increased, the ventricular rate very slightly so. To explain the divergent types of ventricular complexes one might consider the possibility that the intrinsic ventricular pacemaker was frequently shifting, or that the different impulses started at the same point and traveled either along different routes or at varying rates along the same route. Complete heart block without anatomical lesion in the auriculoventricular system might possibly be of neurogenic or of circulatory origin, or it might be ascribed to chemical agents, to asphyxia, or to some hindrance to the passage of impulses from the terminal arborizations of the conducting system to the ventricular musculature. A previous example of possible functional heart block had been reported by Dr. Alfred Cohn. In his case of transient complete dissociation, showing constantly varying ventricular complexes, the patient recovered, so that there was no opportunity of determining whether or not there was an organic lesion in the auriculoventricular system.

Dr. Alfred E. Cohn said that the case reported was a unique one. There occurred many cases of heart block in which nevertheless after death no lesions of the conducting mechanism were found. This was a case of heart block without any cardiac lesion being found. The theories so far presented were quite useless, although quite numerous. Therefore, he thought it might be interesting to show one curve taken of a patient whom it was his opportunity to observe. This individual had a similar condition, but entirely recovered from the lesion as was shown when he was examined some six weeks later. There seemed to be no effect upon the coordination mechanism.

Dr. Theodore B. Barringer, Jr., said that the case reported was certainly a very interesting one, and, so far as he knew, unique. The personnel of the board of experts who made the histological examination (Drs. B. S. and A. Oppenheimer, Dr. Cohn, and Dr. Aschoff) made it certain that the auriculoventricular system was normal, morphologically speaking, and they were obliged to conclude that it was a question in this case of functional heart block. The conception of heart block as arising from functional disturbances of the bundle was by no means a novel one. They were all familiar with heart block arising from digitalis, or from the toxins of infectious diseases, or from vagus influence. This type of functional block was, as a rule, incomplete, transient in character, and occurred most often in patients whose auriculoventricular systems were already defective. Dr. Barringer said he had seen two cases of complete heart block in which influences other than morphological changes aided materially in inhibiting the conductivity of the bundle of His. One was a case of digitalis poisoning in a young man, whose polygrams showed no disturbances of conductivity until the day when complete dissociation ensued. The rhythm was different from ordinary heart block in that the ventricles beat more rapidly than the auricles and also quite independently of them. There was no autopsy. The second case concerned a man whose heart showed varying degrees of dissociation, alternating with periods of normal rhythm. During a period of complete block, one-fiftieth of a grain of atropine administered subcutaneously, increased the ventricular rate from 39 to 74 per minute in 35 minutes. The bundle in this case was probably defective and vagus inhibition sufficed to produce a complete block. In the case of Drs. Oppenheimer and Williams, they were obviously not dealing with a functional block due to toxins or digitalis, and the atropine experiments, it seemed to him, would eliminate any possibility of vagus influence. The cause would have to be one whose action was persistent and the sclerosis of the nodal artery was the only one, apparently, which would answer this requirement. As far as he knew, this was the first reported case of functional heart block, the details of which had been so flawlessly worked out that one was obliged to concur in the diagnosis which Drs. Oppenheimer and Williams had only suggested. They were both to be congratulated most heartily.

**The Cause of Metastasis Formation in Cancer.**—Dr. Isaac Levin read this paper.

Dr. F. C. Wood said that questions regarding the different influences which caused metastasis of cancer were of great importance. In animal experimentation it should be remembered that the conditions were different in animals than they were in human beings. In the latter the mechanical factors of metastasis had been studied. The size of the cell played an important part. In cancer the small cells were more apt to involve the lymph nodes; ultimately in the internal organs the large cells would be found. Another factor, unquestionably a mechanical one, was the lymph flow. Still another factor which did not play such a great part was ameboid action of the cancer cell itself. Dr. Wood called attention to the striking growth of the cancer cells at the periphery. He gave some of the conditions influencing metastasis in the human being which were interesting to all.

Dr. James Ewing said he wished to draw attention to a prominent statement that had been made, namely, that any previous injury to organs influenced the growth of cancer as well as of metastasis in animals; if this statement could be demonstrated as true it would be a very important observation. It was a curious fact about their knowledge, or lack of knowledge, of cancer that the important questions were so obscure; therefore, it should be the aim of those who were working in this line to throw any new light possible upon the problems involved. More work might be done on the blood stream itself and in this connection he called attention to the work of two men in Vienna who were working along this line and said that if the announcements made by them were true they were of great importance. Dr. Ewing said he could not miss the opportunity of saying something regarding metastasis which he considered of great importance, that acute traumatic metastasis was produced by the operator at the time of operation. He spoke of the energetic manner in which the patient was prepared for operation. Another point which had impressed him had been the period at which the metastasis was liable to occur. Good results no doubt would be obtained by educating the physician, especially regarding the development of these secondary growths.

### Philadelphia Neurological Society.

At a stated meeting held April 25 Dr. F. X. Dercum demonstrated a woman, about 45 years old, who had been shown at an earlier meeting on account of masticatory tic and in whom the symptoms had been relieved by suggestive therapeutics.

Dr. Samuel Leopold exhibited "A Case of Brain Tumor." The patient was a man, 54 years old, who for more than a year had impairment of vision, with hallucinations of seeing bunches of grapes at times. Examination disclosed the presence of optic neuritis on both sides, more marked on the right, but there was a total absence of headache and of motor and sensory phenomena. Gait, station, speech, reflexes—all were normal. In the absence of localizing symptoms a decompression operation was performed over the right motor area, but no growth was found. The optic neuritis, however, subsided, but a slight paresis developed on the left side of the face and in the left upper extremity. It was thought possible that a slowly growing growth might be present in the cerebello-pontile angle.

Drs. W. B. Cadwalader and E. P. Corson-White presented a communication entitled "The Relation of Syphilis to Progressive Muscular Dystrophy." They reported a number of cases of muscular dystrophy in which serological tests indicated the previous existence of syphilis. Of course, no final conclusion could be drawn as to the etiological connection of the two facts, but the association was certainly suggestive.

Dr. Charles W. Burr exhibited "The Brain from a Case of Acromegaly." The patient had been demonstrated at a previous meeting of the society and presented classic symptoms of acromegaly. Post-mortem examination disclosed, in addition to chronic lesions of liver, kidneys, and heart, a persistent thymus and a tumor of the hypophysis cerebri of considerable dimensions.

Dr. Thomas B. Holloway presented a communication entitled "Bilateral Pigmentation of the Cornea, Associated with Symptoms Simulating Multiple Sclerosis," and demonstrated the patient. The case occurred in a man, about 30 years old, who over a period of two years exhibited coarse intentional tremor, first of one hand and then of the other hand and slight slurring of speech, with a florid complexion and slight brownish pigmentation of a limited area of each cornea. The case was supposed to fall into the category of hemochromatosis with multiple sclerosis.

Dr. Milton K. Myers demonstrated "A Case of Tabes Dorsalis with Unusual Features in an Epileptic Woman." The patient, about 34 years old, had been having attacks of petit mal for sixteen years, with an occasional attack of grand mal. Insidiously, without pain, difficulty in walking developed and the knee-jerks were found absent. There was a history of venereal infection.

Dr. Morris J. Lewis presented a communication entitled "The Treatment of Chronic Sciatica." He reported two cases in which, other measures failing, an incision was made over the course of the sciatic nerve on the posterolateral aspect of the thigh and adhesions of the nerve freed. In each instance the patient was relieved and there has been no return of pain; nor were there any disagreeable after-symptoms.

Dr. John K. Mitchell presented a communication entitled "The Return of Reflexes and Other Curiosities of Tabes." He referred to cases in which the knee-jerks persist, at least for a time, in the course of tabes, and to others in which they return after having been absent; to some cases in which the Argyll-Robertson pupil was wanting, and to others in which it returned after having been absent; to some cases in which there was return of sexual power previously wanting, especially after treatment with testicular extract.

Dr. N. S. Yawger presented a communication entitled "Extensive Hemorrhage Into the Pia of the Brain."

---

### Pathological Society of Philadelphia.

At a stated meeting held May 8 Dr. Robert A. Keilty presented a specimen illustrating Lane's kink of the bowel; also an aneurysm of the arch of the aorta compressing especially the left bronchus in such a way that breathing was difficult when the head was held vertically in the line of the body, relief being afforded by inclining the head to the right. He demonstrated, further, tissues from a woman who presented brownish discoloration of the face, neck, and arms, and also of the mouth, esophagus and stomach. There had been hematemesis during life, but no other definite history could be obtained. In manipulations about the floor of the pelvis the soft tissues proved friable and the finger was readily pushed into the vagina, whence an odor of ammonia became evident. The uterus contained a fetus at an early stage of development. Apparently the woman had introduced cotton saturated with ammonia into the vagina for the purpose of inducing abortion, and failing in this she had swallowed the ammonia, with the result of causing the corrosive discoloration of skin and mucous membranes observed.

Dr. Charles W. Luders presented a communication entitled "The Theory and Effect of Vaccine Therapy in Typhoid Fever, with Report of Cases." The results of clinical observation show that the treatment of typhoid fever by means preferably of an autogenous vaccine, a stock vaccine being employed until the autogenous vaccine can be prepared, brings about a distinct reduction in the mortality from the disease and also a diminution in the percentage of relapses.

Dr. John Auer of the Rockefeller Institute, read by invitation a paper entitled "Studies on the Heart in Serum-anaphylaxis." It is the rule for animals receiving an initial injection of horse-serum to die soon after receiving a second injection of the same character after an interval of two weeks or more. Under these circumstances a sudden and noteworthy fall in blood-pressure takes place, together with changes in the action of the heart due to disturbances in conductivity. At times heart-block occurs. That these phenomena had a peripheral origin is shown by the fact that they occur even when the vagi are cut.

Drs. Howard T. Karsener and Joseph B. Aub of Harvard University presented a communication entitled "An Investigation of the Origin of Immune Serum Necrosis of the Liver." In experimental observations upon cats it was found that preparations of liver substance caused thrombi in blood-vessels of the liver, in which were found large anerobic bacilli morphologically resembling those described in dogs under similar conditions.

Dr. John A. Kolmer read a paper entitled "Concerning Agglutinins for the *Treponema pallidum*." By suitable technique it was possible to demonstrate the presence of specific agglutinins in blood-serum obtained from syphilitic patients.

---

## Books Received.

*The* Medical Record *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

Contribution a l'Etude des Propriétés Bio-Physiques des eaux de la Bourboule. By P. Gastou and P. Ferreyrolles. Part I. Paper; illustrated; 41 pages. A. Poinat, Editeur, Paris.

Contribution a l'Etude Physiologique et Thérapeutique des Injections Hypodermiques d' eau de la Bourboule. By P. Gastou and P. Ferreyrolles. Paper; part 2; 36 pages; illustrated. A. Poinat, Editeur, Paris.

## Therapeutic Hints.

**Iodine Vaporization in Therapeutics.**—Boissart describes a method of applying the antiseptic power of iodine, which method has been devised by Louge of Marseilles. It consists in the direct application of iodine vapor to cavities normally closed, to fistulous tracts, to the surfaces of wounds, to the ear, and to the uterine cavity. The essentials of Louge's method consist in the heating of iodoform contained in a flask and the conduction of the iodine vapor generated therefrom through a glass tube, the distal end of which is drawn out to a fine point, and which is applied to the cavity or surface to be treated. The antiseptic property of iodine renders this method of particular value in the treatment of infected wounds, and of cavities that are not readily accessible to the ordinary therapeutic agents.

Vaporized iodine is of eminent value in the treatment of tuberculous cavities and sinuses, furuncles that have been incised, anthrax, and chronic suppurations of the ear or of the mastoid. It is also of value in the treatment of uterine affections, such as simple metritis, inoperable cancer, and puerperal infection. In the last instance the iodine vapor is introduced into the uterine cavity by means of a double-current glass sound (iodine attacks metal). Varicose ulcers and soft or hard chancres are also favorably influenced by means of iodine vaporization. The duration of the individual treatment is three or four minutes. Louge has proposed the employment of this method in the treatment of synovitis, the vapor being introduced into the joint cavity by means of a syringe after the fluid has been evacuated.—*Gazette des Praticiens,* April 1, 1913.

**Subarachnoid Injections of Neosalvarsan in the Treatment of Cerebrospinal Syphilis.**—G. Marinesco of Bucharest does not believe that the impermeability of the meninges for salvarsan and other remedies furnishes a sufficient basis for the use of these substances by injection into the subarachnoid space. The fact that a substance administered intravenously or subcutaneously does not appear in the cerebrospinal fluid is no proof that this substance is not brought into contact with the nervous system. On the other hand such a substance is carried in the capillaries, and is transuded from the blood to be taken up again by the perivascular sheaths. It is almost certain that the lymph of the central nervous system does not flow into the cerebrospinal fluid, or, at any rate, passes into the latter only to a minimal extent. Bearing the above facts in mind, one cannot attribute the unfavorable results obtained in cerebrospinal syphilis by means of the subcutaneous or intravenous injection of salvarsan to the impermeability of the meninges with reference to this substance. These unfavorable results are to be attributed rather to the peculiar nature of nerve tissue, severe lesions of which are not amenable to cure. In many instances irreparable damage has been done to the nerve tissue long before any resort is made to neosalvarsan therapy.—*Zeitschrift für die physikalische und diätetische Therapie,* April 1, 1913.

**The Use of Formalin in Rectal Surgery.**—R. Engel has observed the good effects following the use of a sitz-bath of a six per cent. aqueous solution of formalin in the postoperative treatment of anal and perianal affections.—*Le Progrès Médical.* April 26, 1913.

### THE PROPHYLACTIC AND THERAPEUTIC VALUE OF FRESH AIR IN SCHOOLS AND HOSPITALS, INCLUDING HELIOTHERAPY.*

BY JOHN W. BRANNAN, M.D.,

NEW YORK.

THE title of my paper does not fully express what I wish to talk about this morning, for what I have in mind is not so much the air within the school and within the hospital as it is the absolutely pure fresh air to be found just outside their walls. Not all of our school children nor all of our hospital patients can be taught or treated in the open air, but a very large proportion of those who need it most can enjoy this privilege, and it should be our duty as physicians and guardians of the public health to see that they get it to the largest possible extent. Those who must remain indoors should receive the maximum amount of fresh unaltered air that can be admitted through open windows and transoms. I shall attempt to show rather by pictures than by words what has been accomplished in schools and in hospitals up to the present time.

FIG. 1.—Seabreeze Hospital. View at 6 A. M. in spring. Children sleeping on porch all night. Canvas overhead rolled back.

It was a long time after the discovery in 1882 of the bacillus of tuberculosis by Koch before the outdoor treatment of pulmonary tuberculosis became thoroughly established. But many years before 1882 tuberculosis of the bones and joints and glands in children, known probably then as scrofula, was treated in the open air. The hospital at Berck on the coast of France was established by the city of Paris in 1861, the French believing that this form of tuberculosis was favorably influenced by the air from the sea. Even long before this date, in 1797, a hospital was founded by two English physicians at Margate, on the coast of England, for scrofulous disease in adults as well as in children. This is the only institution of the kind in England, but on the continent there are between 75 and 80 marine sanatoria, situated on the Baltic, the North Sea, the Atlantic Ocean, the Mediterranean, and the Black Sea. The original municipal hospital at Berck has been followed by several large private institutions, so that there are now at Berck between two and three thousand beds for children with surgical tuberculosis, about half of them maintained by the city of Paris, the others supported by private endowment. In 1904 the Association for the Improvement of the Condition of the Poor of New York, impressed by the favorable results

*Read at the International Congress on Hygiene and Demography at Washington, D. C., September 25, 1912.

obtained at Berck, decided to establish a small hospital for children with surgical tuberculosis at Sea Breeze, the summer home at Coney Island, which has been maintained for many years by the association, for by day. But it is what I have seen at Sea Breeze during the past nine years that has led me, wherever I have a voice or can obtain a hearing, to urge that not only our patients with pulmonary tubercu-

Fig. 5.—Bellevue Hospital. Open-air treatment of pneumonia in children.

the children of the tenements of the city. The number of beds is restricted to 43, but now that the city has finally purchased Rockaway Beach we have reason to expect that a new hospital with 150 beds will be constructed and completed in the course of the next two years. The Board of Estimate and Apportionment has voted to accept the hospital, for which $250,000 has been subscribed, as soon as it has been completed by the association, and to maintain it hereafter as a city institution. What has been accomplished at Sea Breeze is probably known to many of you, for though the hospital may be modest in size, we have not allowed its light to be hid under a bushel. I shall therefore not impose upon your patience with any further description of the methods pursued there, but shall content myself with showing a few pictures of the daily life, by night as well as

Fig. 6.—Gouverneur Hospital. Children on open balconies.

Fig. 4.—Bellevue Hospital. Roof scene.

losis or with surgical tuberculosis should live in the open air, but that all of our patients, whatever their disease may be, and all of our school children, whether predisposed to tuberculosis or not, shall be placed in an atmosphere approximately the same as that out of doors.

At Berck, as at the other European seaside sanatoria, the children pass the day on the beach or on balconies open to the air and sunshine. This régime was adopted at Sea Breeze, and in the nine years since the opening of the hospital there has not been a day in all seasons and in all weathers that the children, including bed cases, have not been in the open air. At night the windows of the wards are wide open throughout the year. In the warm season the sashes of the windows are entirely removed. From April to November about one-third of

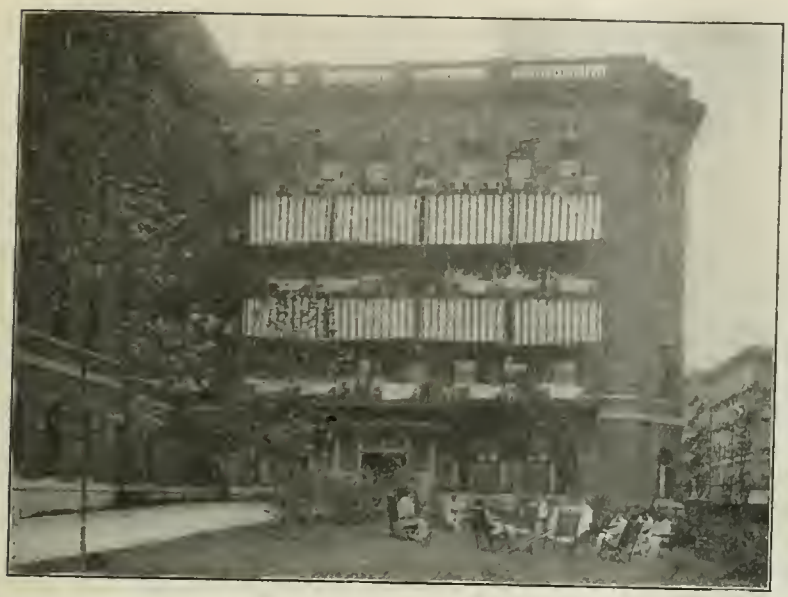

Fig. 7.—Harlem Hospital. Bed patients on balconies, also convalescent patients on lawn.

the children, as many as can be accommodated, sleep on the open porch. Throughout the summer months the ambulant children bathe in the ocean every day, and the nurses repeatedly call attention to the rapid improvement of the patients and the closing of sinuses under the influence of the sea water. During school hours the children are in a room with open windows or in a tent open on all sides, a teacher and a kindergartner being supplied by the Board of Education.

The good results obtained with the children at Sea Breeze were so uniform and so striking that it was decided to provide open balconies in all the hospitals then in process of construction in the department of Bellevue and allied hospitals. Every ward has at least one balcony attached to it, so that every patient, whatever his disease, may have the benefit of the outdoor air which in the past has been thought necessary only for tuberculous patients. In addition to the balconies there are large wide loggias at Bellevue and extensive lawns and roof gardens at all the hospitals but one. Gradually storm sashes and louvre windows are being added to the balconies so that even in the winter the patients can be moved out of doors, one or more sides of the balconies being always open for the free entrance of the outer air.

It is surely unnecessary for me to emphasize the stimulating effect of this treatment upon patients who under ordinary hospital conditions are confined to more or less poorly ventilated wards. It is, however, not easy to express this effect in figures or in percentages of recovery. In one disease, the acute pneumonia of children, an attempt has been made to reduce the results to figures. Previous to November, 1908, the children with pneumonia were cared for in a large sunny ward in the old building. The ward was fairly well ventilated, but there was no opportunity for outdoor treatment. After moving into the new building it became customary to place the children on the balconies for three or four hours a day, unless the weather was too stormy. The good effects of the fresh air were so noticeable that in January, 1910, it was decided to place the patients on the balcony as soon as the diagnosis of pneumonia was made, and to keep them there throughout the twenty-four hours, and this practice has continued up to the present time. It was noted that the patients, with rare exceptions, improved in all their symptoms, especially during the winter months, but no comparative study was made until a few months ago. The results of this study are as follows: From January, 1904, to November, 1908, 274 children

Fig. 9.—Graham School, Chicago. Fresh air obtained simply by raising window-sash.

Fig. 8.—Open-air school, Providence, R. I., showing windows trussed up to ceiling

Fig. 10.—Open-air class of tuberculous children on ferry-boat "Southfield" at Bellevue Hospital. Winter view.

(one year of age and over) were admitted to the hospital, and of these 69 died, a mortality of 25.2 per cent.; in the second period, from November, 1908, to April, 1912, 391 children (one year of age and over) were under treatment, of whom 42 died, a mortality of only 10.7 per cent. The observations of Dr. John Howland, the attending physician in charge of the children's service, and his assistant, Dr. B. Raymond Hoobler, apparently show that this remarkable effect of the outdoor treatment is largely due to the increased blood pressure caused by the fresh cold air. As these studies have been published elsewhere, I shall not refer to them in detail, but will simply state that the rise of the blood pressure out of doors was attributed by these observers to the reflex stimulation of the vasomotor centers by the action of the cold air on the skin of the face and on the mucous membrane of the nose.

Infants under one year of age are also placed in the open air as soon as the diagnosis of pneumonia is made, and adult patients are treated on the balconies or in a room with the windows open so that the temperature approximates that out of doors. These patients uniformly do well, but no statistical study has been made of the results. The effect of the cold air in quieting the restlessness and delirium of pneumonia, especially in alcoholic subjects, is very striking.

Maternity cases are removed to the balcony in from 4 to 7 days after delivery; during the warmer months within 36 hours in some instances. The good effects are evident to all, and particularly to the women themselves. The nurse in charge states that the patients sleep better and call for less attention than when in the ward. A week or ten days (and nights) outing on a Bellevue balcony is not a bad substitute for Lakewood or Atlantic City.

Fig. 12.—Open-air class for anemic children at Public School, No. 21, New York City.

Fig. 11.—Open-air class on ferry-boat "Southfield"—sleeping hour.

Dr. Gregory, the hospital alienist, reports that the effect of open air upon the acute insane is very beneficial, especially in the excited and restless. It has a quieting influence and induces sleep. The same is true of the alcoholic patients of whom there are thousands in the hospital annually. The fresh air and oxygen seem to furnish the stimulation which they greatly need, so that they eat and sleep well. It has been Dr. Gregory's experience that if alcoholics be kept in the open air they will recover much sooner than if kept in the wards. The tremulousness and anorexia and mental depression disappear very quickly. In functional nervous diseases the value of the open air treatment is generally recognized. It induces sleep,

improves the appetite, and supplies the general stimulation which patients of that class require.

Patients after severe operations gain rapidly when taken out of doors. In critical cases the stimulus of the fresh air often seems to turn the tide. The patients themselves are prompt to show their gratification, especially the women, using the words "fine," "lovely," "splendid," and "very nice," in expressing their appreciation. One woman, one of the group on the lawn shown in picture, when I asked her how she liked being in the open air, replied with much feeling that "it made her sleep all night and took away all her pain."

Passing on to the consideration of the open-air

Fig. 14.—Heliotherapy at Leysin, Switzerland. Children with bone tuberculosis.

schools, we may divide them into three groups, first, those for children with pulmonary tuberculosis; second, those for children who are anemic, underweight, and ill-nourished, and hence consid-

Fig. 15.—Heliotherapy at Leysin. Child with a 32 foci of tuberculosis. Cure after 15 months of treatment.

ered to be especially predisposed to tuberculosis, and third, those for normal school children who are neither tuberculous nor predisposed to tuberculosis or any other disease.

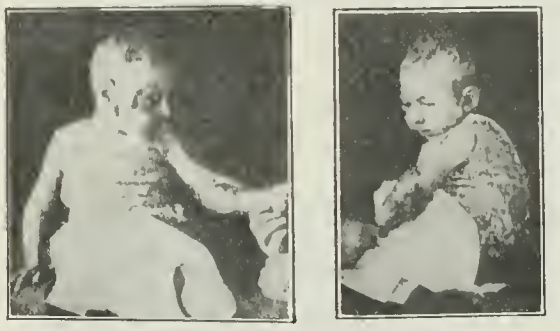

Fig. 16.—Results of heliotherapy at Leysin. Complete extension and flexion of diseased elbow joint after 13 months' treatment.

The open air school movement began in 1904 with the "Waldschule" at Charlottenburg, and was followed in 1907 by the outdoor school at Bostall Wood in the outskirts of London under the auspices of the London County Council. Other schools were soon established in various parts of England, of which those at Bradford and Sheffield are per-

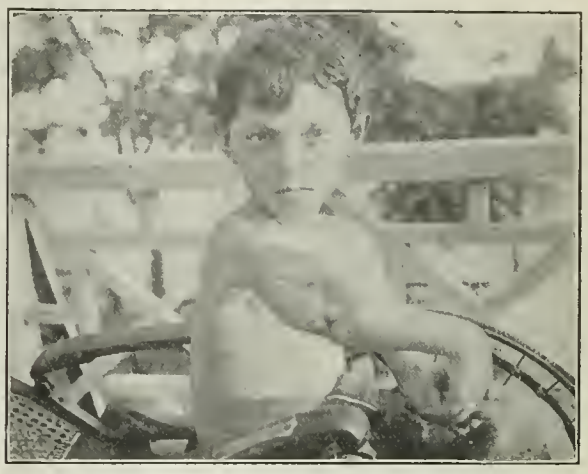

Fig. 17.—Heliotherapy at Seebreeze Hospital, June, 1912—boy with tuberculosis of elbow, shoulder and axillary glands—open sinuses.

haps the best known. In January, 1908, the movement spread to the United States and with the opening of the school term this autumn there will be in operation over 200 fresh air schools and classes for tuberculous, anemic or normal children, according to a statement of the National Association for the Study and Prevention of Tuberculosis. In Germany and in England structures especially designed for the purpose were erected for the children. In this country we have been content as a rule to make use of buildings already in use, either by selecting a room facing the south and altering the windows or by covering and partially enclosing a portion of the space on the roof.

The first school in the United States, with the exception of the hospital school at Sea Breeze already referred to, was opened in Providence. This was followed closely by the Franklin Park School in Boston. The Providence school is in an abandoned school house from which a portion of the south wall was removed and replaced by windows which can be trussed up to the ceiling. The class in Boston is on the roof of a building built for a

refectory in a public park. It is freely open on all sides; protection in stormy weather is secured by curtains which can be dropped as desired. The

results obtained in these schools were so satisfactory that they were soon followed by the establishment of similar classes in Hartford, Chicago, New York, and other cities. These schools vary greatly in their construction and arrangement, but they all agree in supplying fresh air in abundance to the pupils. In Hartford the class is held in a tent, in Chicago and in New York some of the classes are on the roofs of school or hospital buildings. In the Graham School in Chicago the fresh air is obtained simply by raising the windows of an ordinary school room. Two of the New York schools are of especial interest, being located on the upper deck of old municipal ferry boats.

Fig. 19.—Heliotherapy at Seabreeze Hospital, October, 1912. Children on beach. Cured cases of tuberculosis of elbow, wrist and ankle (open sinuses in each case).

Most of these classes are for tuberculous children who have been excluded from the public schools. The régime is the same in all—life in the open air, nourishing food, rest in bed after dinner, and the systematic use of gentle exercises. The results also are practically the same in all—gain in weight, disappearance of the physical signs, and improvement in general condition, both physical and mental. As an instance of these good results, the teacher of the class on the Gouverneur ferryboat reports that of 37 children who had been in the class for periods varying from six months to a year, 30 had been readmitted to the public schools by the physicians of the Board of Education. It should be added that the pupils have not only regained their health, but have also kept pace in their studies with the other children.

In the second group of open air schools belong the classes for anemic children established in the public schools of New York by the Board of Education. The children in these classes have no physical signs of disease, except enlarged glands in some cases, but they are anemic, under weight, ill-nourished, and many of them from tuberculous families. The first class was opened in April, 1910, in public school No. 21, in Mott Street, the center of the congested Italian quarter. Forty such classes have been authorized by the Board of Education and at the present time twenty are in successful operation in various parts of the city. The same routine is followed as in the schools for tuberculous children. The food is provided by the committee on tuberculosis of the Charity Organization Society, a private association, all other expenses being met by the city, through the Department of Education.

The results in all the fresh air classes are excellent. During the first winter the children in the Mott Street school gained on an average of 6 pounds apiece, with a corresponding improvement in all other respects. The increase in hemoglobin is especially interesting. Starting at an average for the class of 71 per cent. in the autumn, the figures reached 85 per cent. in the spring, whereas a control class of normal children in the same school, declined from 87 per cent. to 81 per cent. during the same period of time. At the end of the school year, the twenty-one children had so improved that they were returned to their former classes and a new group of anemic children took their places. Dr. Doty, the superintendent, reports that practically all the children in the school are anxious to join the fresh air class.

As the cost of the extra food is considerable and seemed likely to limit the number of open air classes, it was decided to lessen the amount of food in the new classes, and in some instances no extra feeding at all has been furnished, the children having only the usual dinner provided at home. As far as can be judged by a few months' trial, the children in these later classes are doing nearly as well as in the original class of school 21.

The third group of open air schools, those for normal children in the public schools, is in some respects the most interesting, and full of promise for the future. Having demonstrated that pure air fresh from outdoors can be given not only with safety but with great benefit to school children who are tuberculous or whose health is otherwise impaired, the next step is to give fresh air to all school children. A fresh air class was opened last winter in public school No. 9, at the request of a number of parents of the children. With the permission of the Board of Education the room was

Fig. 20.—Heliotherapy at Seabreeze Hospital, March 18, 1913. Cured case of tuberculusis of knee. No sinus.

cut off from the ventilating and heating system of the school building and the windows were kept open as in the anemic classes. The children receive no extra food, as the parents are well able to provide for them at home. Classes have also been opened—ten in all—in various private schools in different parts of the city, including the Ethical Culture School, the Horace Mann School, the Friends' School in Brooklyn, the Packer Institute, and the Brooklyn High School. There is no statistical record of the results of the schools, but the teachers all feel that much good has been accomplished and the parents are very much pleased. The chief interest, however, attached to the schools of this group lies in the evidence they afford that the public, and parents in particular, are beginning to appreciate the value of fresh air for their children during school hours and are preparing to demand it of the school authorities. In Boston, Chicago and other cities the movement for fresh air schools for normal children is also making progress, so that it would seem to be only a question of time when all children will be taught in the open air.

In conclusion, I should like to say a few words about heliotherapy, limiting myself to its use in surgical tuberculosis, especially as practised by Rollier, at Leysin, in the Vaudois Alps, Switzerland. Rollier established his hospital for the treatment of tuberculosis of the bones and joints as long ago as 1903, and has presented papers on the subject at at least three international congresses, but it is particularly during the last two years that his work has attracted attention. Other physicians had made use of the sun cure on the shores of the Mediterranean, joining it to the "cure marine," and Bernard had practised it in the pure mountain air of the Engadine. It was the work of Bernard that led Rollier to select an elevated site for his hospital. I shall speak but briefly of his methods and his results as the lantern slides present both so clearly that but little word description is necessary.

Leysin is situated at an altitude of about 4500 feet above sea level. The hospital buildings face the south and are protected by mountain ranges from the cold winds of the north and west. Rollier states that even in midwinter the temperature on the sunny balconies is often as high as 45° to 50° Fahrenheit. Owing to the purity of the atmosphere and the absence of moisture, there is no loss of the luminous and caloric radiation of the sun. The exposure to the sun is gradual, beginning with five minutes three times a day. This is steadily increased as pigmentation of the skin appears until finally the entire surface of the body is exposed from sunrise to sunset. The head is protected as shown in the illustrations. With the development of the pigmentation the cure progresses until the recovery is complete; how complete it is may be seen from the pictures of the two boys, the first of whom had 32 foci of tuberculosis, even the lungs being involved, the second, multiple lesions including a badly disorganized ankylosed elbow with seven sinuses and a history of three resections of the joint and forearm. Fever was present in both cases. After one year's treatment both boys are well, with complete return of function—full flexion and full extension—in the elbow of the second boy. I am not an orthopedic surgeon, but I know what is considered as a cure of a tuberculous joint. I have seen many such cures at Sea Breeze. Arrest of the disease with ankylosis of the joint in as useful a position as possible is accepted as a satisfactory result. Rollier regards the pigmentation as an important element in the cure. It gives to the skin a remarkable resistance, favors the cicatrization of wounds and confers a local immunity to cutaneous microbic infections. On days when there is no sun, recourse is had to radiotherapy for the adults and the Bier treatment for the children, and at all times, whether the sun shines or not, the skin has its bath of air and light, as it is put by Rollier.

During the past two years Rollier's methods have been followed by several surgeons at lower levels, where they did not have the advantage of the intense sunlight of Leysin nor the actinic action of the sun's rays at the seashore. The experience of Bardenhauer of Cologne is referred to in a recent number of *La Presse Médicale*. During the spring, summer and autumn of 1911, the season was unusually favorable at Cologne, and Bardenhauer exposed his cases of surgical tuberculosis to the sun in the manner prescribed by Rollier and reports results approximately the same as those obtained at Leysin. Other surgeons have had a similar experience.

The work of Rollier was brought to my attention some two years ago but it was not until last spring that it was decided to add the sun cure to the "cure marine" at Sea Breeze. In April treatment was begun with the first case and we now have fifteen patients exposed for several hours a day. In each case the joint or bone most affected was selected for the first exposure. In only two cases, both of long standing and of highly nervous temperament, did we have to interrupt the treatment. It is of course too early to claim permanent results so far as concerns the local lesion, but there can be no question as to the effect on the general condition and the spirits of the patients. The children themselves are perfectly delighted to get rid of their clothing and probably wonder why we never thought of it before.

The writings and demonstrations of Rollier and other surgeons practising in the mountains of Switzerland have tended to create the impression that heliotherapy and the cure d'altitude are synonymous, a view which is vigorously disputed by Calvé of Berck in the August number of *Archives de Médecine des Enfants*. Calvé and Ménard claim that the actinic action of the sun's rays is at least as powerful at the seashore as in mountain regions. Since the construction of the new open pavilions at Berck facing the sea, all sinuses and suppurative lesions are left uncovered and exposed directly to the sea air throughout the day and are but lightly covered at night. Under this treatment healing progresses more rapidly than formerly, according to Ménard. This practice is now followed at Sea Breeze, with the addition of sunlight. At last the skin of the child, at least the child with surgical tuberculosis, is coming into its own, the free enjoyment of its natural elements, air, light, and sunshine. Let us hope the day is at hand or not far distant when all children may share in this health-giving and life-saving privilege.

# THE ROB.

By JOHN BETHUNE STEIN, M.D.,

NEW YORK.

VOLTAIRE once said to the Margravine of Baireuth, sister of Frederick the Great, "Often an air of truth mingles itself with the biggest lie."

The "rob" or "robb" played a prominent part in one of the most curious episodes in the history of medicine. This secret so-called antisyphilitic specific has had a more or less extensive sale not only in France but in other countries from 1761 to 1910, and, so far as I know, is still on the market.

The mysterious exotic word "rob," which is Arabic in origin, meaning "a confection of fruit juices," was well selected for this secret remedy, which received not only the sanction of the Royal Medical Society of Paris, the approbation of Louis XVI, and of the French government during the revolution, but also the approval of Napoleon, who later offered the inventor 1,000,000 francs for the secret. During Napoleon's sojourn at Elba his sister, the beautiful Pauline, Princess Borghese, sent to Paris for two bottles of 'The Rob-Laffecteur," but history does not state whether they were for her august brother or herself.

At one time, large quantities of all kinds of mercury, especially the bichloride of mercury, were given for the treatment of syphilis and salivation was considered necessary in order to make a cure. The lesions caused by syphilis and those produced by mercury were confounded and not infrequently the dose of mercury was increased when the use of the drug should have been stopped. Because mercury appeared at times to aggravate the manifestations of syphilis it was considered by some untrustworthy, inefficacious, and even dangerous. Those who "cured" what they called syphilis, without mercury, and the inventors or projectors of antisyphilitic remedies made much use of the fear of "that terrible metal which often produces grave conditions and often leaves obstinate and painful sequelæ at times resulting in death," and their advertisements always stated that they "cured syphilis without mercury."

Boyveau, or as he later called himself, Boyveau-Laffecteur, the inventor of the rob, says, in his "Traité des maladies vénériennes et méthode de leur guérison par le rob antisyphilitique" (Paris, 1814, pages 192 and 193): "A fortunate chance put me in the way of it. I have cured patients who have been 'given up' and I have saved the lives of many unfortunates. I employed all the means possible to perfect a remedy which would heal the cruel wounds which have afflicted humanity during four centuries. It is not sufficient to find the most efficacious herbs, but it is also necessary to know how to combine them, and to vary the doses, following the intensity of their virtues, and to unite them in a vehicle proper to develop their energy for destroying and expelling the morbific material. . . . The principle of my theory was that herbs do not change the constitution of the patients, do not disturb the play of organs, aid the action of the animal economy and are to be preferred, on all occasions, to mercury, which acts only as an element of fire and destroys all that surrounds it. If one places mercury in a copper, silver or golden vessel this terrible agent destroys it. . . . I do not know why physicians advise, with so much ostentation, the internal and external use of mercury, since they cannot control its fatal effects. The French revolution has fewer victims than the sublimé—known in the new chemical nomenclature under the less appalling name of bichloride of mercury—advised by Van Swieten. When will the people of the art be sufficiently wise and humane to renounce this poison?"

Everything favored the sale of "Le Rob-Anti-Syphilitique"—the odd name, the fear of mercury, that it had the sanction of a government, a king, an emperor, a Royal Medical Society; that the royal edict of Louis XVI, September 12, 1778, punished anyone imitating it with a fine of 1,000 livres (one-half going to the king and the other to Laffecteur the inventor); that it was made of herbs and contained no mercury and, the most important fact of all, the magic of it—it was a secret preparation "Every secret remedy performs miracles because it is secret; disclose the secret it becomes inert."

Boyveau further states in his "Traité des maladies vénériennes," etc., page 195: "It was in 1776, with a consciousness which applauds itself for working only for the good of humanity that I presented myself to the commissary of Paris, M. Berthier, who refused to grant his protection to a remedy whose worth had not been proved but who permitted me at my expense to prove it."

On the back of the title page of Boyveau's work just quoted the following can be found: "At first I announced I would present my remedy to the medical society for special reasons, under the name of Laffecteur; but the law to-day requires one to use his own name. I therefore take that of my father, and I will sign it in the future, Boyveau-Laffecteur."

Payenneville in his work ("Histoire d'un spécifique de la vérole au XVIIIieme siecle Le rob de Boyveau-Laffecteur," Laval, 1910) says: "In August, 1810, a document was addressed to the Minister of the Interior at Paris by the commission on secret remedies stating that the 'Rob-Laffecteur' was more or less derived from a depurative syrup invented by Vergely de Velnos which had been authorized by the Royal Medical Society in 1761 and that several persons not connected with medicine, had addressed themselves, through an individual assuming the name of Denis Laffecteur, to the commissary of Paris, M. Berthier, for permission to try their antisyphilitic remedy at the hospital in the barracks at Saint Denis."

From this document, cited by Payenneville and the two statements quoted above, made by Boyveau himself, Boyveau appears to have been the "Denis Laffecteur" who assumed the name of Laffecteur when the request was made to try the antisyphilitic remedy at Saint Denis, and that is how this name became connected and identified with the rob, for it was first exploited under the name of "Rob-Laffecteur." On pages 195, 196, 197 of his work, Boyveau, describing the proving of the worth of his remedy at the barracks at Saint Denis in 1776 on three recruits of the pioneer corps, says: "Dr. Poissonier des Perriers, a physician, and M. le Breton, a surgeon and obstetrician, who is very celebrated to-day, were selected to supervise the experiments. As it was important to avoid any shadow of doubt, I obtained permission from the commissary to have the three patients placed in a reserved room, having three separate locks on the door, the key of one being given to me, the other two kept by the commandant so that I was prevented from entering the room alone. They also had a sentinel outside the door and a guard in the room.

My specific was also placed in a closet having three different locks, of which I kept one key, the other two also being held by the commandant. The specific was sealed in a vessel with the seal of the

Fig. 1.—Dr. Pierre Boyveau.

commissary, of the physician who watched the experiments, and my own. These three seals were broken and the vessel containing my remedy was resealed with three new seals each time the remedy was administered. I did not prepare the tisanes, or have anything to do with the preparation of food for the three soldiers, so that there could be no suspicion of my placing mercury in either. The patients were in a deplorable condition. I treated them, and at the time predicted they were entirely cured. This proof obtained the sanction of the government for my rob." (By an edict of Louis XVI September 12, 1778.)

Dr. Pierre Boyveau and Raffart de Marsilly, a nobleman, were the first to exploit the rob, which they called the "Rob-Laffecteur"; Boyveau probably was the inventor while de Marsilly furnished the funds. It is estimated that they made 150,000 francs a year by selling the rob. The cause of the dissolution of this partnership, which occurred in 1792, is unknown. However, they both continued in the rob business, de Marsilly calling his rob the "Rob-Laffecteur" and Boyveau naming his rob "Rob-Boyveau-Laffecteur."

Boyveau-Laffecteur, as Boyveau now called himself, insisted that he was the inventor of the true rob—the "Rob-Boyveau-Laffecteur"—and the house selling the "Rob-Laffecteur" claimed they had the original rob with the original name "Rob-Laffecteur" and that Boyveau was an impostor. This wrangle served only to advertise both robs.

Raffart de Marsilly and Hoffmann, his son-in-law, and successor, continued the sale of the "Rob-Laffecteur." From Hoffmann the business passed to his son, Alphonse Hoffmann, and was conducted by him until 1849. What became of de Marsilly is not known, but certain manuscripts show that the committee of safety, during the revolution, requested him or his agents to deliver his "Rob-Laffecteur" to the hospitals.

Doctor Pierre Boyveau, who was born at Rochelle in 1750, doubtless came to Paris to study medicine. He married his niece, Jeanne Boyveau, and she bore him fourteen children, seven of whom survived him. Boyveau died at Paris in 1812, leaving an estate valued at 3,000,000 francs. Of the seven surviving children of Boyveau only one, the eldest, Dr. Charles Boyveau, who obtained his degree in medicine in 1820, continued in the rob business.

For the reader who is curious to know what Boyveau, Sr., looked like, I have inserted a copy of an engraving of him made in 1795. He is said to have been prepossessing with considerable bonhomie. Not a few persons were jealous of him, and he had many enemies, but he also had many influential friends, and some partisans in the medical profession, one of the latter, Joseph Devaux, in 1808, dedicated a thesis to Boyveau, entitled "Optimo nec non dilectissimo Boyveau, Doctori medico."

After the death of his father, Dr. Charles Boyveau managed the business of the "Rob-Boyveau-Laffecteur" until 1842, when it was sold to Giraudeau de Saint Gervais for 20,000 francs, and in 1849 the other "only true and original, rob" the "Rob-Laffecteur," was also acquired by the same person for 70,000 francs.

I am inserting a picture taken from Payenneville's work, of a bust made in 1837 and now in the Musée Carnavalet, Paris, of Dr. Charles Boyveau. Some may regard it as evidence that history repeats itself in the fine arts as well as in other walks of life, or that the jest of yesterday may be repeated as sound philosophy to-day.

And now Giraudeau de Saint Gervais plays his part. His name was Jean Giraudeau, he was born at Saint Gervais in 1802, studied law at Poitiers, but giving up this career, came to Paris, studied medicine, and received his doctor's degree in medicine at the age of twenty-three.

"The therapeutics of syphilitic affections without

Fig. 2.—A caricature bust of Dr. Charles Boyveau.

the use of mercury" was the title of his graduation thesis. Toward the end of his term at the medical school he made the acquaintance of one Mme. Jullemier, a midwife, whose interesting memoirs ap-

peared in 1835, and who conducted a much frequented house for accouchements in the neighborhood of the Odéon. Their intimacy favored the fortune of Giraudeau but not that of Mme. Jullemier. Mme. Jullemier had a "purely vegetable rob" of her own composition, and it was to dethrone the "Rob-Laffecteur" which the midwife was "astounded to see still used in a century in which medicine was enriched by so many discoveries." After a time Giraudeau left Mme. Jullemier, but took the midwife's rob along with him and called it the "Rob of Giraudeau."

Here is the formula of Mme. Jullemier's rob, as given in her memoirs—where she alludes to it as follows: "Have confidence, gentle clients. Here is the heroic remedy which M. Giraudeau sells you at 12 francs the bottle. What a wonder of savoir faire":

| | |
|---|---|
| Gentian root | 20 c.c |
| Jalap | 10 c.c. |
| Molasses | 35 c.c. |
| Essence of cinnamon or peppermint | 2 c.c. |

But the two older and better known robs interfered with the sale of Giraudeau's rob, and he therefore bought them both, as we have seen, one in 1842, and the other in 1849. He then exploited all three robs, pretending through his advertisements that a rivalry and competition existed between all three. It is estimated that his advertising in newspapers, almanacs, and by posters cost him 200,000 francs a year.

Giraudeau rapidly amassed a fortune of several million francs. He died at his chateau at Bonffemont on June 2, 1861. It is not known how he obtained the cross of Chevalier of the Legion of Honor or the Greek Order of the Saviour, but he ennobled himself by attaching the name of his birthplace (Saint Gervais) to his own name, calling himself Giraudeau de Saint Gervais.

In "Les Médecins de Paris jugés par leurs œuvres" (Sachaile, 1845), we read: "Alas, we know M. Giraudeau de Saint Gervais, whose name and address are in all the newspapers, he is the chief of those commercial physicians who consider a patient as an object for exploitation only."

The following is an abstract from an article which appeared in a medical journal at the time of Giraudeau's death, 1861: "At twenty-three years of age he became a doctor. Without loss of time, he took his century at its word and imprinted upon its forehead the deep stigma of shame. He introduced into the practice of medicine the shamelessness and power of impudent and lying advertising."

After Giraudeau's death, his sons conducted the business, which in 1882 was sold for some several 100,000 francs.

Payenneville says in his work mentioned above: "The records of the Royal Society of Medicine at Paris make no mention of the composition of the rob; becuse it was understood that the remedy was a secret preparation and also because this society was requested simply to say whether or no the rob contained mercury."

It is certain that the members of the society selected to make this inquiry knew the exact composition of the rob, since it is said, somewhere in their reports, that Boyveau had furnished them all the constituents of his mixture which they made and gave to patients. One of these experts, Bucquet, who had a great reputation as a chemist, said he found no mercury in the mixture made by the committee of the Royal Medical Society, but he did not conclude that it was absent from the mixture. This reserve on Bucquet's part was based upon the fact that after he had introduced a small quantity of mercury in the rob, he was unable to find it in his analysis."

The following is quoted from Boyveau's work, pages 215 to 216, cited above: "On April 19, 1780, this committee of savants declared the radical cure of twelve of the most desperate cases in the hospitals of the capital by means of the rob which the committee themselves had made. Their conclusions contain four articles which I (Boyveau) embody. (1) The Society thinks that the rob of M. Laffecteur, as it has been prepared, does not contain mercury. (2) That the remedy and method of Laffecteur may cure confirmed and desperate cases of venereal diseases. (3) That this method did not exclude special accessory forms of treatment—precautions and modifications depending upon circumstances impossible to define, which must be left to the discretion of the physician. (4) That this remedy containing no mercury may be useful in the cases where either the internal or external use of mercury is feared, such as, for example, when there is a complication of the syphilitic and scorbutic virus."

On the conclusions of the Royal Medical Society at Paris, Boyveau writes as follows (page 216): "After so thorough an investigation of the rob, so many chemical analyses having been made previous to the prodigious cures which were affected before the eyes of, and by the hands of, prejudiced men, I can now announce that I have found a specific, purely vegetable, and much superior to all the preparations of mercury, because it produces a radical cure of desperate venereal diseases."

Payenneville says: "Naturally a great number of authors have pretended to know the composition of the rob (*i. e.* Rob-Laffecteur) and have given the so-called formula but none of these seem to be the true one."

Payenneville thought that the following given by a contemporary of Boyveau approached nearest the formula actually used.

Sarsaparilla, guiacum, cumin, flowers of borage, senna, rose leaves, musk, sugar, and honey. These were boiled down in water to the consistency of a syrup. However, many physicians claimed that the rob contained mercury, as several of their patients who took no other remedy became salivated.

After the firm producing the "Rob-Laffecteur" had sold their business to Giraudeau, they published a list of formulæ which were supposed to contain the true constituents of their rob. Here is one of these which I have copied verbatim from Payenneville:

| | | |
|---|---|---|
| Salseparille | 40 | parties |
| Saponaire | 50 | " |
| Squine, Saxafras, Gaïac | 8 | " |
| Santal citrain, Ecorce de buis, Ecorce de garou | 10 | " |
| Broux de noix sèche | 9 | " |
| Mercuriale | 25 | " |
| Cynoglosse | 30 | " |
| Buglosse | 10 | " |
| Bourrache | 30 | " |
| Chardon bénit | 10 | " |
| Fumeterre, Cones de houblon | 5 | " |

| | | |
|---|---|---|
| Feuilles de scolopendre | 5 | parties |
| Racines de chien dent | 10 | " |
| Racines de taraxacum | 10 | " |
| Racines de chicorée | 10 | " |
| Racines de séné | 40 | " |
| Racines de roses blanches | 40 | " |
| Racines de bécatunga | 10 | " |
| Racines d'agaric blanc | 10 | " |
| Semences d'anis, Semences de persil, Semences de fenouil, Semences de cumin, Semences de carvi, Semences de carotte, Semences de myrthe | aa 5 | " |
| Eau de pluie | q.s. | |

The "Annonces de Normandie," 1778, page 180, says of the rob: "Such a remedy is a beautiful present to humanity."

In 1910 the robs were (and probably they still are), sold in France, each with its distinctive bottle and prospectus, but the price is the same for one or the other. According to Payenneville "the present proprietors of the robs declare that none of them contain mercury, and numerous chemical analyses verify this statement."

It was not, it seems, sufficient for the patient to take a number of bottles of the rob in order to be cured of syphilis, but much caution and a certain ceremonial was necessary before, during, and after the absorption of the divine rob in order to obtain its marvelous effects. "The patient must be prepared by taking a tisane laxative and an emetic, and if he had a tendency to congestion he must be bled. This was followed by a purgative (senna). Sarsaparilla must be added to the rob, notwithstanding the fact that it contained a large amount of this substance. The patient must be placed upon a diet, and because the rob is a depurative and sudorific, the clothes should be frequently changed. He should wear a calico shirt, cotton, or better still, linen, socks" (but it is to be noted that no particular make or quality of linen sock is specified) "and his underclothes should be warmed in winter." They condescended to explain how the cure takes place. "The rob cures syphilis in three ways simultaneously, by dividing, neutralizing, and expelling the dense humors."

The prospectus impressed the fact that the best remedies did not act at first, and therefore the purchaser must not lose patience after taking one or two bottles. It was sufficient if the remedy brought out only symptoms of the disease. The age of the disease had much to do with the number of bottles of the remedy which was necessary for a cure. The climate was of great importance, as it required eight to twelve bottles to effect a cure in France, but in Italy only four to eight.

"One assisted the cure by giving the disease to another person, or at least it was well to treat one's-self among strangers."

Several brochures on venereal diseases were written between 1778 and 1789 signed Laffecteur. In 1789 the following work appeared, "Recherches sur la méthode la plus propre a guérir les maladies vénériennes soit récentes, soit invétérées, par le Dr. Boyveau, médecin à Paris, 1789." In this work Boyveau simply alludes to the rob as a remedy which has given good results in his practice.

Many second-hand copies of works on the rob can be found in Paris to-day. Some are signed Laffecteur, others Boyveau-Laffecteur. These books which treat of the rob are well written, printed on good paper, and are unusually well bound. My copy has the following title, "Traité des maladies vénériennes et méthode de leur guérison par le rob antisyphilitique, par M. Boyveau-Laffecteur, médecin, Paris, 1814," and its subject matter is divided into six parts: The first part treats of the history of venereal diseases; the second part treats of the different methods used to cure syphilis; the third contains the history of the rob; the fourth treats of gonorrhea; the fifth gives the proofs of cures as made by the rob, and the sixth contains petitions, letters on various documents pertaining to the rob, including an ode on the "Rob-Boyveau-Laffecteur."

The following extracts are made from the aforementioned work of Boyveau-Laffecteur: "There are men of the art who have attacked me more or less adroitly. Their attacks are the more perfidious because they solemnly announce that they have analyzed my remedy and have the hardihood to publish a pretended analysis of it in order to increase the number of formulas in their works. Thus Dr. Desbois of Rochefort, who has compiled 'An Elementary Course in Medicine,' affirms that my rob is only another name for the 'syrup of cuisinier.' This in itself is absurd. Swediaur pretends that the rob is a syrup made from the marsh reed, the arundophragmites of Deleschamp, and with good reason adds that this herb has no great virtue in healing venereal diseases. It does not concern me that Swediaur pretends to have my secret, which I surely have not given him, and which will contribute nothing to his art or fortune."

And to Swediaur's statement: "But I believe there are few patients who are radically cured by using this remedy without the previous use of mercury," Boyveau-Laffecteur responds on page 222, "One understands from this that the English doctor (Swediaur) says to his patients: 'First pay me to give you mercury, which will not cure you, then take the rob which will cure you.'" After devoting five pages to attacking Swediaur, he closes his chapter on the history of the rob as follows: "I do not attach much importance to this critic. This writer shines but little in medicine and his book does not show that he had great success in the art of healing."

Boyveau further states: "On April 1, 1781, I was commissioned to furnish my rob to the ships and the marine hospital. This commission was renewed on August 8, 1788. On December 1, 1793, the government commissioned me to deliver my rob to all the ports during the war. On September 29, 1794, the committee of safety gave me the right to export my remedy wherever the interests of humanity demanded and ordered the custom authorities to allow the cases of my rob to pass without a permit. This proof of confidence on the part of the government has continued without interruption from April 1, 1781, to this day. Our august Emperor, to whom humanity is dear, has not withdrawn to this day the confidence with which I have been honored. The report of the medical society, April 19, 1780, of which I have given an extract, accepts the confidence with which I am honored not only in France, but in foreign countries. I have invited the health officials in the capitol and provinces to test a specific that thirteen physicians pronounce harmless and efficacious, and which has the approbation of the medical society and the sanction of the government. The papers report what has taken place—the happy results of the first treatments. Confi-

dence has been established by the cures which multiply; and on all sides demands are made for stations for the distribution of my remedy."

What the rob was, whether or not it contained mercury, are conjectures. Time proved that it did not cure syphilis, and its vogue gradually fell off. But the exploitation of this remedy did much harm in inculating false ideas in the minds of the layman regarding the treatment of syphilis which are not entirely eradicated to-day.

The reproach against Boyveau is that he exploited, through the credulity of the suffering poor and an ignorant public, a secret so-called specific which he sold at the exorbitant price of twenty-four francs a bottle, and the therapeutic value of which has not been proved after a century's use.

Was the rob altogether a fraud? Was it a big lie with a little truth? Does the secrecy which surrounds it wholly damn it? "In science," says the physiologist Bunge, "we are fully justified in not accepting a conclusion until the grounds upon which that conclusion is based are laid before us."

205 East Twenty-third Street.

## THE ACID TEST IN THERAPEUTICS.

By JOHN AULDE, M.D.,

PHILADELPHIA, PA.

In selecting this topic for discussion at the fourth annual meeting of the American Association of Clinical Research, held in New York on November 9, 1912, I was guided by a desire to establish certain fundamental principles as a basis or foundation for clinical research, believing that the chemical problem in nutrition overshadows in importance all other questions. Hence, *the significance of the acid test*—to determine the physiological equilibrium as well as the chemical status of the body fluids and tissues. Although every physician is supposed to be thoroughly familiar with the scientific facts relating to acids and alkalies, as laid down in our text-books on physiology and chemistry, there is a dearth of information concerning *the effects* attending chemical deviations in the body fluids, blood and lymph. Thus, special attention has been given to the stomach in the case of hyperchlorhydria, without any efforts being made to correct or remove the effects—in the form of obscure nervous phenomena—directly traceable to the "habit" of the system which has given rise to the acid excess.

The original paper on this subject was submitted to a friendly critic for comment, in the expectation that any "unreasonable" claims would be pointed out—and I should evade the charge of "fictitious abstraction." In replying to the criticisms I have rewritten the article for the purpose of showing that we have to deal with demonstrable facts, scientific and clinical, susceptible of analysis and synthesis.

The importance of the chemical problem in nutrition depends upon the absolute necessity of inorganic matter to promote function—we should have no physiology without chemical stimulus. All vital phenomena in animals and plants are regulated, modified or governed by the chemical reactions of the nutritive pabulum—and the correlation is complete.

While plants take up carbon dioxide and throw off an equivalent of oxygen, and in animals the process is reversed, the protoplasmic cells are indistinguishable. Besides, the cell-sap, or nutritive pabulum in growing plants, is alkaline in reaction—just like the human blood under normal conditions, and oxygen is essential to their growth. Moreover, when plants are "cut" and placed in water the stems "swell" and become firm, and the chemical reaction of the cell-sap is changed to acid—like the blood-serum in the frog's leg when a ligature is applied at the thigh and the animal is allowed to remain in water; the tissues are swollen and tense. The counterpart of this phenomena is seen in nephritis—and it is believed to be due to colloid-chemical changes, the increased hydration capacity being caused by an abnormal production or accumulation of acid. Chemical deviations in the body fluids, therefore, may give rise to what might be termed a "habit," a self-perpetuating disorder, such as hyperchlorhydria.

*The obscurity connected with kidney disorders* supplies an apt illustration—while they have been differentiated and studied in detail, we still have no definite or demonstrable data to offer in the matter of treatment, simply because we have not yet fathomed the mystery of the causative factors responsible for their appearance. Indeed, the present outlook is rather discouraging—when it is claimed that kidney disease itself is the cause of the coincident or consecutive arteriosclerosis, whereas the kidney disease is but a local manifestation of constitutional derangement. A critical study of the chemical relations must convince the impartial student that Bright's disease is curable, in the sense that neuritis and neuralgia are curable. That is to say, a diminished alkalinity of the blood passing through the kidney tissues has interfered with function and destroyed structure—in other words, an excess of acid has produced organic disease.

Clinical observation shows that this increased hydration capacity or edema may be measurably controlled by the normal salt solution, and also that it can be permanently relieved by the employment of chemicals (lime salts), which restore to protoplasmic cells the inorganic proximate principles, the lack of which interferes with function. In addition should be mentioned the important clinical fact that recovery will be hastened by the conjoint administration of alkalies—to neutralize acid excess. Hence, the significance of the acid test—to determine the physiological and chemical status of the nutritive pabulum.

That *obscure nervous phenomena* may be due to acid excess is readily susceptible of proof, because the plan of treatment advocated causes them to disappear—a clinical fact and not a mere coincidence, since the results may be calculated with a certainty approaching mathematical precision, provided degeneration has not produced structural changes in the cells.

*An acid salivary reaction is* a short-cut in making a diagnosis, and might be misleading, unless corroborated and confirmed by other evidences. We have the acid mucus from the labial, buccal, palatine, molar, and lingual glands; also the alkaline or neutral saliva from the parotid gland, through Steno's duct, from the submaxillary gland, through Wharton's duct, and from the sublingual gland, which is supplied with from ten to twenty ducts (ducts of Revini), under the tongue. All told, the salivary glands produce approximately three pints daily—and a reliable test can be made by placing the moistened litmus paper directly *under* the tongue. In the case of severe attacks of typhoid, diphtheria, scarlet fever, and other serious illness, this method should be adopted, *after* the buccal cavity has been

rendered aseptic—to guard against the local effect of bacteria.

When it is stated as a clinical fact that an acid salivary reaction is a constant and persistent factor in disease, and that it is due to diminished alkalinity of the blood, and *not* to the presence of mucus or bacteria, nothing is assumed, because it can be demonstrated. Further, it is not necessary to prove that the saliva is not acid in perfect health, because it is admitted in text-books on physiology and by experimental investigators that under normal conditions the saliva is alkaline or neutral.

While hyperchlorhydria and so-called Bright's disease are chronic ailments, they represent essential conditions common to all disorders, acute, subacute, and chronic, functional and organic, and the complication incident to bacterial invasion requires no special line of demarcation, since the acid test still retains its ascendency.

The acid salivary reaction of hyperchlorhydria and Bright's disease (nephritis) represents essential conditions common to all disorders, but it does not follow that this is a primary condition, since it precludes the possibility of constitutional reaction—as in the incipient stage of tuberculosis, and perhaps in other diseases, such as cancer, where the reaction of hydrochloric acid is diminished or arrested—it disappears.

*The nature and significance of acid excess* will be readily understood by a brief recapitulation of certain well-known chemical changes incident to metabolism, as follows: The blood, under normal conditions, is alkaline in reaction; the lymph, together with the chyle, which unites with it in the thoracic duct, is also alkaline; likewise the products of glandular activity, except the kidneys, so that the upbuilding processes (metabolism), are constantly alkaline. Additional evidence in support of the proposition is to be found in the tissues—alkalescence is their normal status.

That anabolism, the up-building process, is an alkaline process must be patent when we observe the effects attending chemical deviation in the body fluids, blood and lymph, the evidences of malnutrition, as in chronic diseases. Indeed, they are conspicuous and multitudinous — chronic intestinal catarrh, with an increased output of acid mucus, bronchial catarrh, with atrophy or thickening, nasal catarrh with deafness, eye troubles, headaches and neuralgia, all are due to the same condition; and in the case of membranes and tissues dependent directly upon the normal alkalinity of the blood for their integrity, the rule still holds good—stiffness of the joints arising from a diminished alkalinity of the synovial fluid, muscular rheumatism, consecutive to involvement of the fibrous sheath; a low grade of inflammation attacks fibrous and serous structures throughout the body, from which the nerves do not escape, shown by neuritis and neuralgia, together with all the various forms of degeneration. Even the ductless glands, which exercise such an important influence upon the vital activities, do not escape. Bone structure also suffers; there is softening or "wasting" and condensing ostitis, shown by a multiplicity of deformities and deviations from normal.

Thus, we might proceed indefinitely to recount isolated and correlated scientific and clinical facts to establish principles, even laws—and this is analysis or induction. But the converse of this proposition also has alvantages—having a complete and satisfactory explanation of all the phenomena, the process is reversed and the facts stated from known principles—by deduction or synthesis. The following succinct and comprehensive exposition of analysis and synthesis is to the point:

"Induction in physical science . . . calls in the aid of deduction when hypotheses are formed to explain certain phenomena, and then it is tested by tracing them downwards to what would be their results whether they are true or not. On the other hand, geometric demonstration seeks the aid of analysis as a guide to the solution of its problems. And not only in subordinate points, but as wholes, the two methods supplement each other. There can be no concrete science which does not begin with induction, and there is no complete science unless it ends in deduction."

With a single exception, the gastric fluid, all retrograde changes (catabolism) are characterized by acid reaction, acid urine, acid perspiration, and acid mucus. Therefore, the deduction is warranted that the normal condition incident to anabolism is alkalescence, while acidity is normal as regards catabolism. Not only in the cases mentioned, but in every case the presence of acid in excess must lead to impairment of function, and ultimately to changes in structure. In all such instances, therefore, the therapeutic diagnosis points clearly to the employment of remedies for the purpose of neutralizing acid excess.

This one notable exception, the acid reaction of the gastric juice, by no means invalidates the rule relating to the incidence of alkalescence and anabolism. Rather, it is a factor tending to strengthen the rule, because it is in fact *complementary and conservatory* in maintaining the chemical equilibrium, and besides, the stomach is directly responsible for the formation or development of new chemical compounds by oxidation, deoxidation, or other reactions. In other words, the reaction of the gastric juice supplements acid elimination by utilizing it and at the same time performing important functions in the process of metabolism which could not be accomplished as well by any other or all the other facilities connected with the primary assimilation.

The significance of this chemical deviation, however, cannot be appreciated from the mere didactic statement of its existence, although it is no longer an academic question, awaiting the decision of a jury selected to determine the weight of the argument, pro and con, because the effects are definite and demonstrable by clinical evidence, confirmed by instruments of precision. The clinical as well as the scientific evidence completely supports the hypothesis, so that the conclusion or final decision may be reached by either induction or deduction.

Here we enter an unexplored region. The landmarks outlining the vast territory, as already mentioned, have been standing for generations, yet no one has had the temerity to venture beyond its borders, unless we except Sylvius and his followers of the iatro-chemical sect, who made some tentative discoveries, little understood, nearly two hundred and fifty years ago. Viewed in the light afforded by modern scientific research, this "find" gives promise of rich rewards to the clinician—through its direct influence upon health maintenance. Besides, in the treatment of disease two factors of paramount importance have been added to our therapeutic armentarium—simplicity and efficiency.

Sylvius was an enthusiastic investigator in both anatomy and chemistry. It was he who demon-

strated the fissure separating the parietal from the temporosphenoidal lobes, since known as the fissure of Sylvius. As a chemist he founded the iatrochemical sect, teaching that health depended upon the relation of the fluids, acid and alkaline, their union producing a neutral and milder substance; two kinds of disease were recognized, the result of either acid or alkaline acridity.

Among the followers of Sylvius should be mentioned Glauber, the discoverer of sodium sulphate (Glauber's salt), and Willis, the celebrated English anatomist. To the latter belongs the honor of demonstrating "the remarkable arterial anastomosis at the base of the brain," known as the "circle of Willis"; in addition, he described and named the cranial nerves, and was probably the first to outline the characteristic features of diabetes, so that "Willis' disease" was long used as a synonym.

The latter half of the seventeenth century was notable for the number and character of its medical devotees, and it seems almost incredible that they failed to distinguish the normal alkalescence of the building-up from the normal acidity incident to the breaking-down processes in both animal and plant life.

Having now pointed out the relative functions of acids and alkalies in the human economy and advanced the hypothesis of acid excess leading to injurious effects, even organic changes, it remains to show the practical application of the acid test as a guide in therapeutics; in other words, it is a question of adaptability.

The problem in nutrition, as previously intimated, is a chemical problem, and when a chemical deviation leads to derangement of function and ultimately to changes in structure we must or should endeavor to trace *the effects* by a study of the cause or causes responsible for their appearance, and for this purpose the acid test is immediately available because of its adaptability. Moreover, from a therapeutic viewpoint it is the only reliable test supplying a legitimate and logical basis for medication and treatment. Any other basis, except as expedients for emergencies, must be relegated to the mechanical aspect of treatment, like strychnine, digitalis, and nitroglycerin for heart disease, along with the associated degenerations.

When impairment of the primary assimilation (indigestion) has given rise to lime depletion through acid excess, together with a surplus accumulation of magnesia, there is ample warrant for the hypothesis of *substitution*. And since we *know* that magnesium nucleoproteins lack the property of imbibition (absorption) it is a logical deduction that the "substitution" interferes with function. Here we have induction and deduction in juxtaposition, to show the folly of mechanical treatment in the cases mentioned, the proof being found in the fatalities.

A word should be added here relative to *the effects of chemical deviation*, and again we see the advantages of analysis and synthesis—induction and deduction. While no free magnesium salts are found in the body fluids and tissues, we *do* have carbonates and phosphates; why not magnesium oxide, due to the action of oxidase, a constant product of cellular activity? Tracing this hypothesis downwards—with the known scientific fact that magnesium oxide (calcined magnesia) combines chemically with organic colloids—the complete solution of the question is simplified. That is to say, the abnormal deposits of magnesium involving the nerve structures and interfering with function may be dispersed or caused to disappear, provided the integrity of the colloid structures has *not* been destroyed and the "irritation" has *not* resulted in new tissue formation. To promote magnesium dissociation, treatment must be regulated to meet the special condition presenting. In the class of cases mentioned we have to deal with chemical transformation, the second division of the classification adopted, "The Chemic Problem in Nutrition," Philadelphia, 1912, an alterative being demanded (iodine), together with an appropriate lime salt (carbonate, phosphate, or sulphate), to restore the lacking inorganic proximate principle, but we must also at the same time adopt suitable measures to eliminate or neutralize acid excess. Neither of these measures alone would afford more than temporary relief, but taken together they complete the chemical circle and produce the desired results. Incidentally, it may be remarked, the successful management of this class of cases not only emphasizes the advantages of induction and deduction, but also confirms in no uncertain manner the paramount importance of the acid test in therapeutics.

As a preliminary it will be the part of wisdom to state definitely the effects arising from acid excess, a convenient term to designate a diminished alkalinity of the blood. Taking intestinal indigestion for the purpose of illustration, we know that it means fermentation of the undigested starchy foodstuffs, together with decomposition (probably) of nitrogeneous material which has escaped from the stomach, leading to the production of nitrites, so that to the acid incident to fermentation we have added the acid arising from microbic invasion (multiplication). As a consequence the urinary acidity is increased, the perspiration is more acid than normal and may be augmented, while the output of mucus is greater, along with hyperchlorhydria, all going to show the conservatism of Nature in her efforts to relieve the intestinal embarrassment, an alkaline or neutral medium being essential. Testing the blood under these conditions will show diminished alkalinity, which lessens its oxygen-carrying capacity and interferes with oxidation. Consecutively, we have diminished alkalinity of the lymph, the lymph-glanular apparatus being impaired, which seriously deranges the leucocytic function and permits multiplication and distribution of bacteria and their toxins, not to mention the dangers from cytotoxins.

A critical study of intestinal indigestion as related to magnesium infiltration would be intensely interesting if we could impress upon physicians the deleterious action of magnesium on function and structure by establishing a continuous and complete chain of clinical and scientific facts in support of the hypothesis. The phenomena embraced under the head of fermentation of starchy foodstuffs with decomposition of nitrogenous material escaping from the stomach in a partially digested form and introducing an additional bacterial flora are scarcely sufficient. Clinical observation shows diminished alkalinity of the blood, increased acidity of the urine and perspiration, and also an augmented output of mucus, and coincidently we observe evidences of suboxidation, impaired glandular activity or lymphstasis; leucocytic action is in abeyance and consecutively the multiplication and distribution of bacteria and their toxins direct attention to the fluctuations in temperature, when antiseptics are demanded. The "*missing link*" is to be found in the derangement of

function, due to the presence of magnesium deposits which impede, hinder, or destroy the capacity for the uninterrupted transmission of nerve impulses.

This hypothesis is susceptible of clinical demonstration, for example, in the case of children suffering from intestinal disorders incident to the summer season. After complete failure to secure *permanent* improvement by the routine methods in vogue, Pasteurized milk, intestinal antiseptics, and colonic flushing, the employment of calcium salts (lime) will establish convalescence almost immediately, a few hours being quite sufficient to effect a marvelous change. In this class of cases we *assume* that the acid excess has depleted the lime content, and that it has been replaced by magnesia, so that we have to deal with simple replacement—a deduction. To remedy this chemical deviation we administer lime in sufficient dosage to promote magnesium dissociation according to the law of mass action, first proposed by Guldburg, a Norwegian physicist, confirmed later by Van't Hoff (Studies in Chemical Dynamics), the celebrated Rotterdam chemist, who established it upon a scientifis basis.

*The demonstrable effects of acid excess* are to be found by a study of metabolism—in respect to the absorption, transportation, and elimination of certain inorganic proximate principles, especially lime and magnesium. Thus, the acid excess incident to intestinal indigestion depletes the lime content of the tissues, leading to various nervous symptoms, including anemia and lack of bone-making material. In convalescence, for example, a diet composed largely of crackers is responsible for delayed recovery, and not infrequently relapses may be traced to an unsuitable dietary, which favors or permits lime depletion.

When we understand *the importance of lime salts in promoting function* and maintaining structure, the deleterious effects of lime depletion are patent, even without the coincident or consecutive derangements arising from magnesium infiltration. A demonstration of the injurious effects of magnesia, when replacement or substitution takes place, would add strength to the hypothesis—a question which has to deal with physiological chemistry and relates to the absorption, transportation, and elimination of both calcium and magnesium.

A critical examination will solve the mystery in part at least, but laboratory research must complete the work.

Bone structure consists principally of lime, as does also that of the teeth. Let children subsist upon a dietary deficient in lime, the evidences of impaired nutrition soon become apparent, not only in the lack of bone-making material, but also in the retarded growth and mental development, and the distended abdomen places them in the strumous class.

The fetus has been described as a calcium parasite, and we know something about the peculiar nervous symptoms incident to the vomiting of pregnancy—although clinical observation shows that an appropriate lime salt will cause their complete disappearance in a few days or a week.

When we place this clinical data side by side with the scientific fact that the maintenance of rhythm is dependent upon the presence of calcium salts, reacting with potassium and sodium, we get a slight conception of the important function performed by mineral salts, but the clinical evidence advanced rather upsets the theory that disease is due to "mineral starvation."

As will be shown presently, the chemical deviation in the body fluids interferes with the mineral equilibrium or adjustment. For example, muscular tissue in man contains 1 part calcium to 3 parts magnesium, while the human brain contains but 1 part calcium to 10 parts magnesium. Should this chemical deviation cause depletion of the lime content as claimed, then we should find exactly what our text-books on physiology teach us, namely, that a deficiency of lime in the blood-stream leads to a lack of muscular tonicity and nervous excitability, a symptom-complex which is characteristic of neurasthenia. By deduction, therefore, the corollary follows that calcium is curative in neurasthenia, although it does not cover the vital facts relating to substitution or replacement by magnesium which impedes, hinders, or destroys the capacity of the nerves for the uninterrupted transmission of impulses.

*Calcium depletion involves also the integrity of ferments.* Physiologists tell us that without a proper supply of calcium the fibrin ferment is defective, which interferes with the coagulation of the blood; other unorganized ferments (digestive ferments) suffer in like manner. We notice these clinical effects in the treatment of various disorders, anemia, and diathetic disorders, and notably during convalescence from acute diseases. The defective leucocytosis in all diseases, and particularly in general debility, supplies additional evidence that lime depletion inhibits function. The absence of lime, therefore, becomes the pivotal factor in anemia with deficiency of hydrochloric acid—and may be the "missing link" in the case of cancer. And here should be mentioned the reports emanating from London, relating to the antidotal action of potassium salts in cancer, as reported by Dr. Forbes Ross. A theory is advanced that cancer is due to diminution of potassium salts, "an exhaustion of a natural quality of the body possessed by epithelial cells." Potassium citrate or bicarbonate is employed internally, and a solution of the phosphate locally, by means of the electric current. My impression is that this method, while it develops certain favorable points, is still incomplete. The internal medication, the well-known "neutral mixture" (liquor potassii citratis) is effective in promoting alkalescence of the body fluids; the local use of potassium phosphate possesses distinct advantages, owing to the fact that all potassium salts act as protoplasmic poisons at the points of elimination (Bartholow). (According to Beneke, potassium phosphate is *essential* to the formation of blood corpuscles.) We can understand how the liberation of potassium in the tissues may act as a protoplasmic *stimulus*, while the acid radicle unites with calcium, and it is not necessary to dwell upon the peculiar advantages of calcium phosphate. In addition to its nutrient properties, if given in sufficient quantity, it promotes magnesium dissociation, so that this new treatment of cancer hinges upon two of the three cardinal principles of the proposed classification—it aims to neutralize acid excess and promote magnesium dissociation.

It should be added that the presence of lime exercises an important influence upon fat metabolism, because it promotes function, while the substitution of magnesia hinders the transportation of starch, and besides, we have clinical evidence that it seriously interferes with the glycogenic function of the liver.

Finally, it will be in order to note the association of calcium and phosphorus; although acting in com-

bination as well as separately, they must be regarded as complementary, and with an unsuitable dietary there is loss of phosphorus as well as lime depletion. Thus, in the case of the experiment with the cracker diet *the daily loss of lime* incident to the intestinal indigestion set up was 17.87 grains, the *daily loss of phosphorus* 11.51 grains, while the *loss of magnesium* was but 2.16 grains. The proportionate loss of magnesium is 11.23 grains; hence, there is substitution.. Interpreted, this means that intestinal indigestion so interferes with function that there is depletion of certain inorganic principles (lime and phosphorus) out of proportion to magnesium depletion; and assuming that this is due to an excess of acid, the logical deduction follows that the chemical deviation is responsible. Hence, rational treatment should aim to restore the chemical and also the mineral equilibrium.

*Mineral depletion* is well illustrated in the accompanying tabulation, covering an experiment in metabolism, the dietary being limited to crackers and water. In the adaptation, grains have been added to show the metric equivalent, taking 15.43 grains as the equivalent of one gram; the explanatory details follow:

"This experiment was begun at 7 A.M., June 3, 1906, and continued three days. In order that the bodily condition of the subject should be as nearly as possible the same as in the second experiment, the diet of the three days preceding the third experiment was the same as in the first experiment, viz., 450 grams of crackers and 1,500 grams of milk per day.

"The weight of the subject (without clothing) was approximately 62.7 kilograms (138 pounds), at the beginning, and 61.8 kilograms (136 pounds), at the end of the experiment. The initial weight was therefore practically the same in this as in the second experiment, and the loss of 0.9 kilogram during the three days was probably due as largely to the hot weather as to the deficient fuel value of the diet.

"The daily diet consisted of 450 grams of the same lot of soda crackers as were used in the first and second experiments, with an average of 1200 grams of distilled water per day. The crackers supplied 43.9 grams protein, 44.7 grams fat, and 339 grams carbohydrates, the total fuel value being 1930 calories."

The average daily income and outgo of mineral constituents an dnitrogen are shown in the accompanying table.

By way of comment, the authors say: "During this experiment the food did not become so distasteful as during the second, but there was some lack of appetite and at times a slight feeling of fullness and thirst after meals. There was also in this, as in the second experiment, a slight tendency toward looseness of the bowels."

Special attention is directed to the evidences of intestinal indigestion, "lack of appetite," with "a feeling of fullness and thirst after meals;" but the effects, in the form of lime depletion, were "conspicuous," simply because the lime being the stronger base, it combines more readily with the acid than magnesia. Hence, the preponderance of lime depletion signifies the substitution of magnesium, and since magnesium nucleoproteins lack the property of imbibition, it follows that magnesium infiltration hinders tissue change and tends to impairment of function. In other words, lime depletion incident to acid excess results in chemical transformation, the organized nucleoproteins being changed into magnesium nucleoproteins, which interferes with function and may produce or give rise to death of the cells.

TABLE SHOWING MINERAL DEPLETION—CRACKER DIET*

| Kind of Material | CALCIUM OXIDE | | MAGNESIUM OXIDE | | PHOSPHORUS | | NITROGEN | |
|---|---|---|---|---|---|---|---|---|
| | Grams | Grains | Grms | Grains | Grams | Grains | Grams | Grains |
| Food per day: | | | | | | | | |
| Bread (crackers)... | .126 | 1.94 | .079 | 1.22 | .401 | 6.19 | 7.02 | 108.32 |
| Distilled water..... | ..... | ..... | ..... | ..... | ..... | ..... | ..... | ..... |
| Total daily income. | .126 | 1.94 | .079 | 1.22 | .401 | 6.19 | 7.02 | 108.32 |
| FECES: | | | | | | | | |
| Total for three days. | 3.690 | 56.94 | .379 | 5.86 | 1.355 | 20.91 | ..... | ..... |
| Average per day... | 1.230 | 18.98 | .126 | 1.94 | .452 | 6.97 | (.70) | (10.80) |
| URINE: | | | | | | | | |
| First day (June 3-4) | .062 | .96 | .086 | 1.33 | .986 | 15.21 | 10.64 | 164.17 |
| Second day (June 4-5)..... | .044 | .68 | .095 | 1.47 | .622 | 9.60 | 10.46 | 161.40 |
| Third day(June 5-6) | .056 | .86 | .098 | 1.51 | .476 | 7.34 | 9.77 | 150.75 |
| Total for three days. | .162 | 2.50 | .279 | 4.40 | 2.084 | 32.16 | 30.87 | 476.32 |
| Average per day... | .054 | .83 | .093 | 1.44 | .695 | 10.72 | 10.29 | 158.77 |
| TOTAL OUTGO per day | 1.284 | 19.81 | .219 | 3.38 | 1.147 | 17.70 | 10.99 | 169.57 |
| Loss per day..... | 1.158 | 17.87 | .140 | 2.16 | .746 | 11.51 | 3.97 | 61.26 |

*Adapted from the Monograph, "Calcium, Magnesium, and Phosphorus in Food and Nutrition," by Henry C. Sherman, Arthur J. Mettler, and J. Edwin Sinclair, Department of Chemistry, Columbia University, New York. Washington, D. C., 1910.

In the case of intestinal indigestion, therefore, we are confronted with *three distinct conditions or deviations from normal*, namely, (1) Impairment of the digestive capacity; (2) Acid excess, shown by the "tendency to looseness of the bowels;" and (3) Magnesium infiltration.

The corollary relating to treatment then is a logical sequence: (1) Restore the digestive capacity; (2) neutralize acid excess; (3) promote magnesium disassociation.

A convenient and reliable method for determining excessive acidity is to be found by testing the salivary secretion with blue litmus paper, or by testing the reflexes, the knee-jerk, for example.

It will not be out place in this connection to point out the serious disadvantages attending medical treatment, and particularly convalescence, when the dietary is not properly "balanced" as regards lime and magnesia. At the same time, it is pertinent to mention that the "sloppy" dietary so popular at the present time, may be responsible in a measure for much of the prevalent illness—especially diseases of the nervous system, the goal in disorders of nutrition.

*Other factors intimately connected with this study* relate to the daily average intake of acids, sulphuric and phosphoric, in the food eaten; the daily intake of chlorine, and also the daily average intake of lime and magnesia, together with the variations according to the food selected, but I have elsewhere ("The Chemic Problem in Nutrition," Philadelphia, 1912) discussed these questions in detail, covering substantially all the ailments in which this chemical deviation is the essential element, the line of demarcation between health and disease. When it is stated that these chemical changes or transformations illuminate and make plain and comprehensible the pathology of arteriosclerosis, neuritis, neuralgia, and neurasthenia, the intrinsic value of the acid test in therapeutics must be apparent. Add to this, diseases of children, in-

fectious and non-infectious, and we begin to grasp the significance of its importance in solving the chemical problem in nutrition—because *it makes for simplicity and efficiency.*

1305 Arch Street.

## PRELIMINARY REPORT OF PERSONAL EXPERIENCES WITH THE FRIEDMANN TREATMENT OF TUBERCULOSIS.*

By GEORGE MANNHEIMER, M.D.,

NEW YORK.

In making this preliminary report I am prompted by the following reasons: (1) I believe that every one who has had experience should publish the facts. (2) I believe that some colleagues might need information on the subject, coming through the accredited channels, to guide them when asked by patients as to the advisability of taking this treatment. (3) In some of my cases the treatment with the Friedmann vaccine is finished. (4) Innumerable premature misleading statements have been given out to the press from the Friedmann camp for advertising purposes, and the man has so conducted himself as time has gone on that he forced every one who has come in contact with him to assume the defensive.

You will remember that they succeeded, by their newspaper campaign, in creating the impression among the public, that he was not given a fair trial on account of professional jealousy. Our tuberculous patients furthermore were made restless and wanted information as to this much vaunted "sure cure"—information to which they were certainly entitled. A number of well-known phthisiotherapists came from distant parts of the country to gather this information at first hand for the benefit of their patients. They and all of us who took the matter seriously were guided by the knowledge that the idea on which this treatment is based is perfectly sound, comparable to the active immunization against smallpox by cowpox, or to the hydrophobia treatment. To quote Theobald Smith, "The use of living virus is the most certain and most economical way of calling for a maximum output of antibodies." This idea had been elaborated and carried out long before Friedmann, and by men of infinitely greater attainments. Of American investigators I mention Trudeau, de Schweinitz, Pearson and Gilliland, Webb, Williams, Barber and Dixon. We had sincerely hoped for a decided progress in the treatment of tuberculosis, which we sorely needed. Judge for yourself, from what I am going to say, whether this has been vouchsafed us by Friedmann.

Eighteen patients were injected by him under my supervision; one on March 6, and 17 on March 8—that is, now about eleven or twelve weeks ago. Twelve have tuberculosis of the lungs, one has tuberculosis of the lymphnodes, two have tuberculosis of kidney and bladder, and all these were injected intramuscularly; two have tuberculosis of the joints, and one has tuberculosis of lung and joint, and all three were injected both intravenously and intramuscularly.

Case I. Married woman, 40 years of age; 5 feet 4 inches in height; weight 156 pounds; under observation 4 years; sick 14 years; tuberculosis in family; climatic treatment; 2 courses of tuberculin; has the usual symptoms, but never suffered much; never hemorrhages; practically afebrile. Marked shrinkage of left upper lobe, with cavity, and very marked pleuritic thickening over left lobe posteriorly. Feels and looks well; attends to household duties; sputum very scanty but positive in summer, 1911; not since. Selected because stationary. Had a slight stich reaction at the site of injection; very little local infiltration, which has disappeared long ago. Friedmann thinks she has improved so much that she needs no further injection for an indefinite period.

Even granted that there were an improvement, that is not sufficient. Since the inventor has called his remedy "curative and protective," we had a right to expect at least apparent cures such as we have accomplished in a fair proportion of cases right along. We are justified furthermore in expecting permanent cures, *e.g.* absence of relapses. But for that, in any of the cases reported so far, the time is too short.

Result of this case: There has been no change either way. She has had periods when she also felt perfectly well and weighed 7 pounds more. Lately has occasional uneasiness and fluttering in the heart region and tachycardia, no doubt on account of the proximity of the lesion to the pericardium.

Case II. Man, 34 years of age; under observation 9½ years. Pulmonary tuberculosis 12 years or more. In December, 1903, weighed 123½ pounds; 5 feet 3 inches; broad chest; had infiltration of right apex with bacilli in sputum, and slight subjective symptoms; improved promptly under hygienic medicinal treatment, always keeping at his work. Received injections of tuberculin from January to March, 1904, his weight increasing 13 pounds. Not seen again until May, 1908, when he developed vasomotor rhinitis, diffuse asthmatic bronchitis, fever, loss of flesh, and dry left basal pleurisy. Had regained his former good condition by December, 1908. Passed by life insurance in 1909. In 1910 weighed 155 pounds. In 1912 much chest pains off and on; always at work in a cigar store; infiltration and shrinkage of right upper lobe and apex of lower lobe, difficult to detect on account of compensatory emphysema; no bacilli. Injected to help along natural healing. Slight stich reaction; local infiltrate, size of a cherry, still persisting after eleven weeks; skin pointing red. Punctured on May 25, and about 5 drops of thick pus evacuated; on staining cells mostly polynuclear, few lymphocytes; no organisms of any kind. Cultures on ordinary laboratory media, at 37 degrees C. after 48 hours sterile.

Friedmann says: Second injection indicated probably in 4 weeks. Result: No change.

Case III. Married woman, 37 years of age; 5 feet 1 inch; 154 pounds. Came from out-of-town for this treatment, beginning of March, since which time I know her. Pulmonary tuberculosis for 8 years. One aunt died of tuberculosis. Was always thin, and subject to colds. Probably acquired the disease by sleeping in a room formerly occupied by a consumptive in a summer resort where she went to recuperate from strain of caring for her troublesome baby. Had the usual signs, fever, sweats, cough, expectoration, hemoptysis, and went down to 87 pounds. Much climatic treatment, and repeated courses of tuberculin. Best weight 175 pounds; March 4, 154 pounds.

Consolidation, massive shrinkage and pleuritic thickening of left upper lobe and left base; induration of right apex; has the best medical care and enjoys all comforts of life; looks and feels well, but still coughs and expectorates about 2 ounces of sputum daily, with bacilli; temperature labile. Injected March 6, and advised by Friedmann to drink a pint of cream a day to facilitate the work of the vaccine. This is the only instance in which he gave advice of any kind. I consider it bad advice in this particular case, because the patient had the limit of adipose commensurate with her well-being. She tried cream for a week, but had to give it up of her own accord. Two days after injection an extravasation appeared at the point of injection, and a slight induration the size of a lima bean. Two weeks later this increased to the size of a plum, soft in the center and tender; the skin red. Patient elated and buoyant; left town. April 25 (7 weeks after the injection), report from her family physician, "Infiltrate broke down and discharged large quantities of pus." Report of May 14. "There is a sinus about one inch deep, leading into a pocket or cavity, which formerly contained pus.

*Read before the Metropolitan Medical Society May 27, 1913.

Opening in skin is oval, ½ by ⅛ inch, and is in the center of a slight depression. Skin around opening has a bluish tint. Both the sinus and abscess cavity are clean and practically free from secretion at this time. About ⅛ inch from the sinus there is a soft spot on a slightly hardened base, with skin slightly blue, which has the appearance of going to suppurate. Inguinal lymphnodes on that side not enlarged. Bacteriological and pathological report has not yet been received. Patient has lost her buoyancy, and is in the same condition as before.

What is the cause of this unusually large abscess? Have the previous frequent administrations of tuberculin anything to do with it? Was it due to puncturing of a vein and admixture of blood with the vaccine? Friedmann does not take precautions to avoid the veins in giving his so-called intramuscular injection. Was the dose too large? All acid-fast bacteria produce abscesses at the site of injection when a certain dose is reached, due to the irritation of their waxy substances which prevent absorption of the bacterial proteids. As I understand, Friedmann uses sterile water as a menstruum, with certain additions. He scrapes off loopfuls of his culture and weighs the scrapings. These he adds to the diluent, and then he filters, using the first portion of the filtrate for intravenous, and the second, the less concentrated, for intramuscular injections. We standardize our vaccines by counting the number of organisms to the cubic millimeter. I doubt whether his method of standardization is more accurate. Résumé: No improvement, but troublesome inuses and infiltration in gluteal region.

Case IV. Girl, 21 years of age, a patient of Dr. Junger. Pulmonary tuberculosis for 8 years. Was then in a sanatorium; improved, went back to factory work, and kept at it with short interruptions. Far advanced, principally left-sided process, which has been stationary for years. 114 pounds; 5 feet. Injected March 8. On the 13th, local induration, size of a silver dollar, red and tender. This broke down April 4 (one month after injection), and discharged pus, which was sterile, on staining; closed on the next and reopened on the following day. April 7, deep induration, the size of a small apple; skin red to the circumference of a 50-cent piece, containing a small sharply cut round hole discharging pus. Patient feels well, coughs little, and expectorates less than half an ounce of sputum. Early in May, when the abscess had closed, but infiltrate still existed, more cough and expectoration, which is difficult to raise, fever, chest pains, loss of weight. Result: Patient is worse. I would not advise a second injection by the Friedmann method.

Case V. Man, 40 years of age, bookkeeper. Pulmonary tuberculosis for over 4 years; under observation since March; 5 feet 8 inches in height; 170 pounds in weight; good chest. Very moderately advanced left-sided lesion. Had tuberculous cervical lymphnodes removed two years ago. Otherwise never sick much; good eater; heavy smoker. No subjective change after injection. Five weeks later had first hemoptysis of his life. Local infiltrate, then the size of a pea; weight slightly decreased. Not examined since April 15. Result: Absolutely negative. Process certainly not checked.

Case VI. Farmer, 38 years of age, came to see me with his family physician for this treatment early in March; youngest of ten children; 6 feet in height; weight 125½ pounds; thorax poorly developed. Pulmonary tuberculosis over 3 years; much climatic treatment, also tuberculin. Left lung shows moderately advanced, right apex beginning disease. Temperature 101°; pulse 116; faint trace of albumin and few hyalogranular casts; slight infiltration of epiglottis. Injected March 8. The same night—without the knowledge of myself and his physician—he traveled approximately 2,000 miles, got married, and returned with his wife. Expressed himself as feeling better, but developed a small periprocitic abscess. After his family physician left he was put to bed and received proper care and medication. Process in lungs progressed under the form of caseous pneumonia, infiltration of epiglottis increasing and left arytenoid became swollen. Had a good infiltrate at site of injection which had long disappeared, when Friedmann examined him again on May 14 and deferred the second injection for two weeks.

This patient has had such confidence in the Friedmann vaccine, that he married on the strength of the first injection. The matrimonial excursion did him some harm, but this was in a way counterbalanced by the faithful care which he received from his bride. Much more was he harmed by the dilatory tactics of Friedmann, who repeatedly postponed seeing him and others, to determine whether a second injection was indicated. The patient was thereby kept in constant suspense and unrest. Friedmann, to my repeated promptings, always replied that he had not taken any money from these patients and would see them in time. He had indeed refused the fee offered, and that fact alone seemed to him sufficient to relieve him from all further duty and responsibility. When he at last was prevailed upon to see the patients, this particular one was found to be ready for the second injection, which was, however, arbitrarily postponed for two weeks. He immediately left the city, greatly disgusted with Friedmann's ways. The patient was ripe for a second injection at least two weeks before he was seen by Friedmann and put off. The local infiltrate had completely disappeared, and he was getting worse. Friedmann says, Reinject under such conditions. Do not reinject as long as infiltrate remains unabsorbed, for fear of setting up anaphylaxis. When the infiltrate has disappeared, but the patient keeps on improving, you can reinject or wait; there is no hurry. The disregard of his own indications makes the neglect in this case the more flagrant.

Now I relate four cases of pulmonary tuberculosis which came under observation in March, and which gave about identical results.

Case VII. A showman, 28 years of age; the youngest of ten children; sick much; 6 feet 2 inches in height; weight 157¼ pounds. Three years ago rectal fistula; then the usual pulmonary signs; short sanatorium treatment; many hemoptyses; sub-febrile, continuous tachycardia. Three and one-half weeks after injection hemoptysis lasting ten days. When reexamined May 10 had lost 7 pounds, but felt fairly well. Friedmann found deep infiltrate, the size of a small cherry, and postponed second injection for four weeks. I took my time and examined patient in various positions for remnants of infiltrate, but found none. Other physicians had found none some time before. The patient, whose funds had become exhausted while waiting, took matters into his own hands, procured the second injection in some other quarter, and left town.

Case VIII. Man, 30 years of age; height 5 feet 9½ inches; weight 139¾ pounds; the youngest of eight children. Formerly excessive smoker and moderate drinker; heart inclined to be rapid; frequent tonsillitis; sick three years; at first not diagnosed. Main symptom dyspnea; fingers clubbed; liver slightly enlarged; trace of albumen. Ten days after injection expressed himself enthusiastically improved; buoyant, breathing freer, expectorating more and easier; subscapular pain gone; appetite much better. But improvement did not last. When reexamined, subjective condition fair, but disease advanced and still spreading. Although no infiltrate present was put off. Received second injection May 26. To-day, 26 hours after injection, infiltrate size of marble, very tender, skin bright red; looks as if it were going to suppurate. Was told to come for third injection in five weeks.

Case IX. Man, 26 years of age; height 5 feet 9¼ inches; weight 130 pounds; the youngest of five children. Always thin and much sick; chronic nasal catarrh; large perforation of septum; a few cervical and both epitrochlear lymphnodes enlarged; Wassermann negative. Disease apparently began 1909, while drumming in the Gulf States; diagnosed as malaria. Some amateur climatic treatment. Perirectal abscess last year. Advanced left-sided process. Ten days after injection no local infiltrate, but coughs looser and more spread out over the day. Four weeks after injection old peri-rectal abscess opened again. Sub-febrile. May 14 reports to Friedmann as feeling fairly well; infiltrate, the size of a marble; to be reinjected in two or three weeks. Was, however, reinjected

on the 24th, ahead of time, although he coughed up a little blood on the 22d.

I had heard Friedmann say that he would not inject any one who had a hemoptysis within a week. But either his statements have to be taken with a large grain of salt, or he does not lay much stress on that particular point—or else this patient was a special favorite. As he himself tells me, he is the brother of a newspaper correspondent who had written up Friedmann before the latter came to this country.

These three patients were up and about as they pleased. They tried to manage their own cases, and being of the erethic or hyperthyroid type, do not offer a good prognosis, unless they submit to strict régime.

Case X. Man, 28 years of age; teacher; sick 4½ years; a wanderer in search of proper climate; height 6 feet; weight 148¾ pounds; highest 188 pounds; clubbed fingers; intestinal disturbances, formerly constipation, now tendency is diarrhea. Very amenable. Put to bed in hospital; continuous slight fever. Although lung condition did not progress, attacks of diarrhea reduced his weight by 6 pounds. May 14 Friedmann felt infiltrate, the size of a pea, and put him off for five weeks. I am positive that Friedmann felt something in a place that was not the site of the first injection. The patient, whose funds were running low, took a second injection in another quarter, on his own responsibility, and left town. He stood the trip to his home in Wisconsin badly; had high temperatures and night sweats. The result in these four cases is so far unfavorable.

Case XI. Physician, 46 years of age; sick since 1907. Tuberculosis of left apex. Careful climatic and tuberculin treatment. In active practice since 1908. Last year fresh cold; feels well; occasional pleuritic pain. Wanted the injection to prevent relapses. After injection chest pain gone, cough less; gain of 2 pounds. At the end of April caught cold again; coughs and expectorates more and does not look as well as before. But objectively process is latent. Result: Negative; is disgusted with Friedmann's methods.

Case XII. Man, 27 years of age, lawyer; height 5 feet 11½ inches; weight 136 pounds on November 21, 1912. Subject to colds the last three years; losing weight and strength. First definite sign, hemoptysis in winter of 1912, repeated several times since. Mild infiltration of both apices, active. Put to bed, and under strict hygienic-dietetic medicinal régime; gained 8½ pounds and lost all signs of activity. After two weeks in Lakewood, N. J., where he gained two additional pounds, was allowed to go to the office. Caught cold February 21, had more cough and expectoration, pain in right chest, fever and sweats, all of which disappeared within three days. March 2d, slight oppression in chest and occasional night sweats; sputum scanty, no bacilli. Injected March 8. On March 11 again the short, sharp pain in right lower chest. March 18 reports himself feeling stronger. March 25 pain in right lower chest and distinct pleuritic friction over right lower lobe posteriorly; 147¾ pounds, the highest weight since beginning of illness. April 21 reports by letter. Laid up in bed since end of March with what his physician called bronchopneumonia, with severe hemorrhages, fever, and appearance of bacilli. Not examined by me since March 25. Apparently does not want the second injection. Résumé. The spread of the disease cannot be attributed to the vaccine, but it certainly was not checked by it.

Case XIII. Man, 30 years of age, collector; tall and well nourished; weight 178 pounds. Tuberculosis of kidney and bladder. Sick since 1905; difficult to diagnose at first. Many operations. July, 1908, left kidney removed; but old symptoms of burning, frequent micturition, pus, shreds and tubercle bacilli in the urine returned and keep up in varying intensity. At work. Cystoscope shows region of left ureter ulcerated. January 8, 1913, left ureter removed. Injected March 8; no improvement; infiltrate broke down and discharged a little pus.

Case XIV. Man, 23 years of age, hospital orderly. Tuberculosis of kidney and bladder; left kidney removed four years ago; still burning, pollakiuria, and mycturia in varying intensity; at work. Had good infiltrate, which still persists slightly; no improvement; tubercle bacilli still in urine.

Both of these patients are supposed to receive another injection in a few weeks.

Case XV. Boy, 4¼ years of age, a patient of Dr. Sam Kutscher. Tuberculosis of cervical lymphnodes since three years. One group had broken down and been extirpated; also adenoids and tonsils removed; chain of lymphnodes along left sternomastoid, largest the size of a small marble; discrete, moderately hard. Ten days after intramuscular injection, infiltrate the size of a walnut, bluish-red, soft in the center. This opened on April 15 and discharged pus; closed and opened again. Boy's general condition always good; no change in lymphnodes. Friedmann calls them fibrous and does not think they can be further influenced by his vaccine.

Case XVI. Boy, 9 years of age, a patient of Dr. E. Oppenheimer; under treatment two years for tuberculous coxitis with dislocation. Began three years ago gradually with pain in hip and limping; six months later dislocation already present. Traction for six months; then short Lorenz plaster-spica, with which he walks around; lungs clear; 45 pounds. *X*-ray shows marked destruction of acetabulum and ileum; head and neck of femur gone; greater trochanter 2 inches higher than on the healthy side; little motion; only slightly sensitive; no abscess. Marked general reaction from intravenous injection; no change in joint condition. Friedmann wanted the plaster-spica removed because according to his notion it would interfere with the circulation of the antibodies. But as the femur will not stay in place without support, this was out of the question.

Case XVII. Man, 24 years of age, butcher; a patient of Dr. Sam Kutscher. Slight kyphoscoliosis. One sister died of tuberculosis. Pulmonary tuberculosis for seven years. Had three large hemorrhages. After the last one, in June, 1912, went to Liberty, N. Y., and improved very much, gaining 15 pounds in three weeks. Advanced left-sided lung process. Since November, 1912, gradual development of pain, disability and swelling of right knee. Circumference of right knee larger that of thigh and calf smaller than the other side. *X*-ray shows marked atrophy of bones of knee-joint, particularly tibia, fibula, and partella; joint surfaces intact; no distinct bone focus. This lesion is due to toxin action, not actual tuberculous deposit. After simultaneous injection had very severe general reaction. Then felt better for a while. But it is natural that after recovery from a sharp, feverish illness a feeling of well-being should prevail. So far, no improvement in either lung or knee. This is disappointing because in fresh bone lesions prompt improvement was looked for.

Case XVIII. Boy, 16 years of age; tuberculosis of right ankle nine years ago; operated, healed. Since seven years tuberculosis of right knee, treated by fixation, aspiration, hyperemia. Typical case; shortening of right extremity; all measurements on the right side, including the knee, smaller than the left; flexion limited; pronounced tenderness in circumscribed area. *X*-ray marked atrophy of all bones of knee-joint; marked bone erosions of femur and tibia, particularly the outer condyles. After injection sharp, general reaction, followed by less pain and freeer motion. But soon the old condition returned. Second injection May 26. Result: No improvement so far. Subsequent note: May 31, site of last injection painful and tender, infiltrate size of marble. Skin red. Site of first injection, made 12 weeks ago, also red and tender—comparable to the flaring up of a previous cutaneous or intracutaneous tuberculin reaction.

To summarize: In not a single one of these 18 cases was there definite improvement to date, attributable to the vaccine. In some the disease progressed evidently unchecked. In no instance did the temperature return to normal. Five of the 18 developed abscesses, 4 of them small, and one large, as above cited in detail. Excepting this case I could not say that any distinct injury has been done by the vaccine. I cannot determine whether the vaccine hastened the progress of the disease where it has occurred.

I should prefer not to make mention of the man himself, but we cannot dissociate him from his remedy. He is so imbued with the efficiency of the latter that he ignores all other well-established and tried measures. This may be due to an inventor's over-enthusiasm, or to lack of knowledge along clinical lines, a natural result of a career spent principally in laboratories. He does not seem to realize that consumption is a complex disease, in the pro-

duction of which many factors enter, not alone the tubercle bacillus, but also mixed infection, and furthermore also, heredity, environment, occupation, habits, character, financial condition, etc. It is at once evident that a vaccine directed against the harmful effects of the original invader cannot possibly effect a cure unaided.

Friedmann's reexamination of patients consisted in palpating the site of injection and inquiries as to subjective symptoms. He never asked me as to the objective changes. Is that the method of a scientist? I emphasize here again, the underlying idea of the treatment is sound. There may be merit in this or similar vaccines. But for the purpose of applying them to individual cases and utilizing to the fullest extent whatever such merit may be requires a high degree of clinical and special training as well as sound, impartial judgment on the part of the physician who is to administer them or teach others to administer them.

The ambulatory treatment as carried on by the Friedmann institute can never be a satisfactory test.

In conclusion, I cannot do better than to quote the sentiments expressed in a recent paper by one of the foremost immunologists of this country, Theobald Smith: "The medical profession should see to it that vaccine therapy does not degenerate into inconsiderate and reckless experiments on human beings, that it does not create false hopes in hosts of patients, and that it does not originate and end in commercialism and the desire to exploit the weak and unfortunate."

For myself, I will say that it is with profound regret, for the sake of mankind as well as for the sake of medical science, that I have reached these conclusions.

# THE RELATION OF SYPHILIS TO PROGRESSIVE MUSCULAR DYSTROPHY.

By WILLIAMS B. CADWALADER, M.D.,

PHILADELPHIA.

INSTRUCTOR OF NEUROLOGY AND NEUROPATHOLOGY AT THE UNIVERSITY OF PENNSYLVANIA; CLINICAL ASSISTANT TO THE PHILADELPHIA ORTHOPÆDIC HOSPITAL AND INFIRMARY FOR NERVOUS DISEASES,

AND

E. P. CORSON-WHITE, M.D.

PHILADELPHIA.

PATHOLOGIST TO THE ORTHOPÆDIC HOSPITAL AND INFIRMARY FOR NERVOUS DISEASES.

The actual cause of progressive muscular dystrophy has not been determined; yet the evidence so far accumulated seems to indicate that congenital influences play the most important part in its development. How it is transmitted from parents to children, or why it appears in children without the same disease being present in the parents still remains to be explained.

Having had the opportunity of studying a number of patients afflicted with this peculiar malady, and having found that the blood serums frequently reacted positively to the Wassermann and Noguchi tests, it appeared as if syphilis might have an important etiological relationship, therefore the notes of these cases are recorded.

The dull details of long physical examinations were purposely omitted, for it seemed quite sufficient for our purposes merely to state that we believe the diagnoses were as correct as clinical observations could be, each case was a typical one, without complications.

In the cases examined, the original Wassermann technique was employed with all of its controls, using as the standard antigen an alcoholic extract of syphilitic fetal liver obtained from Laboratorium für biologische Untersuchungen Wissenschaftliche Abt. des Medic. Waarenhauses A. G., Berlin N. W. 6.

To further control the result, each serum was tested out again, using four different antigens with all the controls: (1) Extract of ox-heart plus 1 per cent. cholesterin, Sachs-Rondini; (2) the McKenzie Browning lecithin-cholesterin emulsion; (3) Lipoid from human heart; (4) Lipoid derived from ox-heart; and by a Noguchi test, using again another antigen, the acetone-insoluble, ether-soluble, lipoid from syphilitic fetal liver.

In *no* case was a dystrophy considered positive unless the test with each different antigen gave a clear cut positive result and the same care was exercised in the results with the families of these patients.

Case I. G. M. Male: aged 18: father alcoholic; mother died, cause unknown. One young sister insane. Patient has typical pseudo muscular hypertrophy and positive Wassermann and Noguchi reactions.

Case II. S. Z. Male: aged 15 years: father said to be well; one older brother, two younger brothers and one sister healthy. One older brother and one younger sister died during infancy, cause unknown. Mother was said to have been healthy but at the time patient was four years old she developed right peripheral facial paralysis. Patient has typical pseudo muscular hypertrophy and positive Wassermann and Noguchi reactions. Mother also has positive Wassermann and Noguchi reactions, and still has facial paralysis (Neurorezidive).

Case III. C. R. Male: aged 12: father died of paralysis (character unknown) but before death diagnosis of optic atrophy had been made. Mother was treated for eye trouble, said to have been iritis. Two older sisters healthy; and two younger brothers healthy. Patient has typical pseudo muscular hypertrophy and positive Wassermann and Noguchi reactions.

Case IV. A. P. Female: aged 8: father died of typhoid fever; mother healthy, but did have two miscarriages preceding birth of patient. One younger brother healthy. Patient has pseudo muscular hypertrophy and positive Wassermann and Noguchi reactions.

Case V. K. W. Female: aged 10: paternal grandfather and grandmother living and well; maternal grandmother died at 46 of pneumonia; maternal grandfather died at 76 of nephritis; father was only child and seemed healthy until 39 years of age when he had a breakdown, cause unknown to wife, who ascribed it to overwork; was ill for two years. First three children were strong and vigorous; fourth pregnancy arising during illness of husband ended in miscarriage at sixth month; fifth pregnancy terminated at term in patient. She was healthy until 3 years old and then developed pseudo muscular hypertrophy with positive Wassermann and Noguchi reactions. Subsequent to birth of patient mother had three successive miscarriages.

Case VI. P. S. male: age 9: maternal grandfather died at 41 years of apoplexy; maternal grandmother died at 49 years, cause unknown; father apparently well and mother delicate in appearance, but she has positive Wassermann and Noguchi reactions though clinical evidences of syphilis were absent. Patient had one older brother who died, cause unknown; one younger sister has positive evidence of syphilis (Hutchinson teeth), and positive Wassermann and Noguchi reactions. One younger sister is frail and backward mentally, but her Wassermann and Noguchi reactions are negative. Patient has pseudo muscular hypertrophy and negative Wassermann and Noguchi reactions.

Case VII. G. S. Age 21: parents and two older brothers and four younger said to be healthy. Patient has pseudo muscular hypertrophy and positive Wassermann and Noguchi reactions.

Case VIII. Father died, aged 39, of hemiplegia; mother apparently normal, died, aged 52 years, of heart disease; first daughter positive Wassermann and Noguchi reactions without symptoms; second child, dystrophy, Wassermann and Noguchi reactions positive; third child, positive

Wassermann and Noguchi reactions without symptoms; subsequently mother had two miscarriages.

Case IX. Father positive Wassermann and Noguchi reactions without symptoms; mother had one miscarriage; first child, girl, died age one month; second child, girl, died of meningitis; third child, boy, died of diphtheria, aged one and a half years; fourth child (patient) dystrophy, Wassermann and Noguchi reactions negative.

Case X. Father not examined; mother not examined; first child, boy, positive Wassermann and Noguchi reactions without symptoms; second child, boy (patient), dystrophy, Wassermann and Noguchi reactions negative; third child, boy, positive Wassermann and Noguchi reactions without symptoms.

Case XI. Father alcoholic and insane; mother, history unknown; first child, girl, insane; second child, girl, insane; third child, boy, alcoholic and insane; fourth child, dystrophy, Wassermann and Noguchi reactions not obtained.

Case XII. Father, some venereal disease; mother died young, cause unknown; first child, girl, frail; second child, boy, dystrophy, Wassermann and Noguchi reactions not obtained.

Case XIII. Father, cause of death unknown; mother normal but had five miscarriages preceding birth of patient who has pseudo muscular hypertrophy. Wassermann and Noguchi reactions could not be obtained.

Fourteen additional cases of dystrophy were examined and in each the Wassermann and Noguchi reactions were negative. No information could be obtained about other members of their families.

Of twenty-seven cases investigated, seven (Cases 1, 2, 3, 4, 5, 7 and 8) gave positive serum reactions. In three instances one of the parents (Cases 2, 6, 9) also had positive reactions, and one (Case 2) of these had facial paralysis which might have been due to syphilis. Unaffected brothers or sisters of patients gave positive reactions in three families (Cases 6, 8, 10). Miscarriages were said to have occurred in five families (Cases 4, 5, 8, 9, 13). Boas,[1] Plaut and Rehem,[2] Noguchi,[3] Nonne,[4] and others incline to the belief that the mere presence of a positive and persistent Wassermann reaction in the blood is in itself sufficient evidence of existing syphilis even though signs of disease are lacking. Latent syphilis has become well known, and only recently Longcope[5] has shown that in some apparently latent cases, syphilitic aortitis may subsequently develop. We do not, however, know of an instance in which syphilitic aortitis has been observed in association with progressive muscular dystrophy.

In drawing conclusions from the foregoing facts we feel justified in assuming that six of our cases of myopathy were infected with syphilis, and that it was hereditary, and was therefore existent before any evidences of myopathy had developed. Whether the presence of syphilis is essential for the subsequent development of pseudomuscular hypertrophy or whether in our cases it was merely a coincidence that two distinct and separate diseases were observed we do not attempt to offer any opinion.

We wish to thank each member of the Neurological Staff of the Philadelphia General Hospital and the Medical Staff of the Orthopædic Hospital and Infirmary for Nervous Diseases for permitting us to use the records of their cases, and also the Social Service Department of the Orthopædic Hospital for their invaluable assistance in locating the patients and in completing our records.

## A NEW CONTAGIOUS GANGRENE IN WHITE RATS.

PRELIMINARY NOTE.

By LEONARD KEENE HIRSHBERG, M.A., M.D.,

BALTIMORE, MD.

The white rats used in the psychological laboratory of the Johns Hopkins University in February, March, April, and May, 1913, have suddenly developed a highly contagious infection that attacks only the feet and legs of the animals. The disease appeared spontaneously in one litter of white rats in January, and soon extended to adjacent cages one at a time by contact until rigid disinfection cut the epidemic down to sporadic outbreaks which are still occurring—May 23, 1913.

This disease—which Dr. J. R. Mohler, Chief of the Division of Animal Pathology of the Department of Agriculture, Washington, tells me is new to him and has never before been described—is characterized by a swelling of the feet and hoofs, which become black and gangrenous and then in many cases drop off. The general health of the rats becomes somewhat affected, they are unable to go through their learning performances, and usually must be killed.

None of them has died and another peculiarity is that the gangrene attacks the hind legs of the rats. Indeed, only in one instance so far has one foreleg become infected with this rat gangrene.

The process begins evidently between the soft tissue of the toes of the rats and spreads thence up into the toes, feet, and legs. It is a typical gangerene with distinct lines of demarkation, but there is an abundance of white fluid pus.

I have isolated the organism which seems to be specific, for when vaccinated into the feet of well rats, the specific gangrene appears. Complete details of the disease and a study of this organism which has been tentatively named gangrenofaciens Hirshbergii, will appear very soon.

1937 Madison Avenue.

**High Altitudes and Diabetes.**—Dutoit mentions the clinical fact that high altitudes exert a favorable influence on diabetes and adds that thus far no satisfactory explanation of this sequence has been forthcoming. One authority attributed the benefit to chalybeate waters (at St. Moritz), while others give the credit simply to physical exercise and out-of-door life. The assertion has been advanced that mountain dwellers do not suffer from diabetes, and statistics show that in the mountain cantons of Switzerland the number of deaths from diabetes is much below the average. Recently Hoessli and Wanner have each seen in this phenomenon evidence that the rarefied air is a stimulant of carbohydrate oxidation. Hoessli saw a complete recovery of a patient with chronic diabetes. It does not appear that any diabetics have yet been submitted to calorimetric tests, but high altitudes are known to bring about increased oxygen consumption and carbon dioxide elimination.—*Deutsche medizinische Wochenschrift.*

**Diphtheritic Hemiplegia.**—J. D. Rolleston states that diphtheritic hemiplegia is usually of embolic origin; in twelve out of eighteen autopsies embolism has been found. Embolism is probably more common in diphtheria than in any other acute contagious disease, being due, as Marfan has pointed out, to an apical endocarditis. The embolism may be found not only in the cerebral circulation, but in the kidneys, spleen, lungs, and even the abdominal aorta, as in Marfan's case.—*Proceedings of the Royal Society of Medicine.*

## THE EARLY DAYS OF MUNICIPAL SANITATION.

IT is reserved for few men to take a leading part in a great reform movement and to witness fifty years later the extraordinary developments of their pioneer labors. The millions of people who enjoy the blessings of modern sanitation and who are frequently too prone to chafe under some of its apparently arbitrary restrictions, never take time to think of the huge difficulties that beset the beginnings of public health work. Almost half a century following the organization of an effective sanitary control of New York City, the citizens of the latter may well pause to take an inventory of its signal achievements in public sanitation and to honor one who laid the broad foundations of its present structure. The people of New York now have the rare opportunity of paying their tribute of gratitude to Dr. Stephen Smith. In the twilight of his years he has written an invaluable narrative* of the health conditions that prevailed in the western metropolis a half century ago. "The City That Was" is an important document in municipal history, an impressive record of the days when grim pestilence stalked unmolested through the streets.

We of the present time can hardly conceive that as late as 1866, the insanitary conditions in New York City were the same as those that had prevailed for two hundred and forty-four years. There was no drainage; the water-supply came from shallow wells contaminated by street, stable, privy, and other filth; the sewerage was primitive; garbage accumulated in the streets; offensive trades such as slaughter-houses were located in close proximity to dwellings; and stagnant pools were scattered throughout the city. To the ravages of the domestic pestilences of smallpox, scarlet fever, measles, and diphtheria, there were added the calamities of typhus fever, cholera, and yellow fever, which came with the high tide of an unchecked immigration. The death rate in New York for the five years preceding 1866 was 38 per 1,000 inhabitants, as compared with only 15 per 1,000 of the present day.

The modern awakening in public sanitation came with the cholera epidemic that devastated England in 1849. The only preventive measures that had been taught up to that time were "flight, fasting, and prayer." The Prime Minister of England when petitioned by the clergy to proclaim a day of "fasting and prayer," replied: "Do works meet for repentance. First make your homes and their surroundings clean and wholesome; then you may with propriety ask Almighty God to bless your efforts at protection against the approaching epidemic."

No heed was paid to this admonition except in one town in the interior of England which reported not a single case of cholera although the latter epidemic ravaged the surrounding communities. The watchword "cleanliness" spoken not by a scientist but by a layman in authority, now became the popular slogan in England, but was not echoed by the people of America until 1866. The decade and a half prior to that date were the years during which Dr. Smith exerted his pioneer efforts in New York City. Typhus brought over by the famine-stricken Irish immigrants brooded in the tenements. There was no Health Department in those days. By the threat of publicity Dr. Smith succeeded in compelling one tenement house owner to clean out a particularly bad focus of disease. The successful outcome of this unprecedented effort, which was backed by the editorial influence of William Cullen Bryant of the *Evening Post*, began the era of reform. The "Citizens Association" appointed a Committee on Public Health. A "Health Bill" was introduced in the Legislature in 1864, but like previous bills of a similar nature this met with defeat through the political influence of the City Inspector who at that time exercised all the health powers in New York. In order to demonstrate to the Legislature the urgent need of efficient municipal health laws, the Citizens Association provided for a thorough sanitary survey of the city. This was organized and supervised by Dr. Smith. The city was divided up into districts, to each one of which a young physician was assigned. House to house visits were made. The results were carefully recorded on maps. In the meantime the Committee on Law drafted a bill. The epoch-making and apparently unprecedented feature of this bill was that the Metropolitan Board of Health was given the autocratic power of creating ordinances without being interrupted by review proceedings or judicial injunctions. This bill was introduced in the Legislature in 1865 and Dr. Smith was detailed to explain its sanitary measures. In a chapter entitled "New York the Unclean," Dr. Smith presents his eloquent plea made before the lawmakers of nearly a half-century ago. This plea consisted of a detailed presentation of the facts recorded and sworn to by the medical inspectors employed by the Citizens Association, together with photographic illustrations which were made by them. The portrayal of the absolute lack of sanitary supervision in a city in which thousands of wretched inhabitants dwelt in the squalor of damp cellars, near which undrained cesspools invited the ravages of pestilence, could not fail deeply to impress the Legislature. But political opposition brought to bear by the City Inspector, whose office would have been abolished by the above law,

*"The City That Was," by Stephen Smith, A.M., M.D., LL.D., Commissioner of the Metropolitan Board of Health, 1868-1870; Commissioner of the Board of Health of New York, 1870-1875. Price $1.25. New York: Frank Allaben, 1913.

again caused its defeat. However, the public were awakened to the need of reform. Health legislation became the prominent issue in the next political campaign, and the following year the "Metropolitan Health Law" became a statute.

Thus triumphed one of the most important movements in modern municipal history. Those of the present generation need not be told of the later outcome of this movement. The volume in which Dr. Stephen Smith has modestly set forth the birth of municipal sanitation in the United States, for New York became an example which other cities soon followed, is a book which all who are interested in public welfare may read with interest and profit.

## CAMPHOR IN THE TREATMENT OF PNEUMONIA.

Pneumonia, called by Osler a self-limited disease against which no method of treatment is of any avail, is, in the experience of very many able and observant practitioners, one of the most amenable to proper treatment, except in the rare cases of massive infection, of all the infectious diseases. Forty years ago James R. Leaming proclaimed the curability of pneumonia by a massive dose, twenty grains and more, of calomel—an early and empirical application of Ehrlich's theory of therapia magna sterilisans. He practised what he preached, for when he himself was attacked with the disease he took calomel—and recovered. Ten or fifteen years later Andrew H. Smith and others demonstrated the value of the salicylates and of creosote carbonate in the specific treatment of pneumonia.

Some years ago August Seibert of this city published a report of a number of cases of pneumonia treated by hypodermic injections of large doses of 20 per cent. camphorated oil, and also gave the results of a number of experiments with camphor injections in rabbits previously inoculated with cultures of the pneumococci. These reports were published in the *Münchener medizinische Wochenschrift*, No. 36, 1909, and in the Medical Record, April 20, 1912. Seibert's observations have been confirmed recently by Leo of Bonn in two communications to the *Deutsche medizinische Wochenschrift*, Nos. 13 and 15, 1913. In the first of these the author says that the experiments thus far made in cases of pneumococcus infection indicate that "camphor has a specific action against pneumonia," and in the second he quotes from Ehrlich to the effect that Böhnke, experimenting on mice in the Institute at Frankfort, had succeeded in curing pneumococcus infection by subcutaneous injections of camphor oil. Iverson also, writing in *Vratch* of January, 1912, reported good results with injections of 20 per cent. camphor oil, and noted that the toxemic symptoms were markedly ameliorated in all cases, even in the alcoholics and in those who finally succumbed. These observations of Seibert, confirmed by workers in Bonn, Frankfort, and St. Petersburg, the favorable results obtained by Wright in the use of mercury succinimide (Medical Record, June 1, 1912) and the earlier successes with creosote carbonate, the salicylates, and calomel should suffice to down the pessimism which so long dominated the therapeutics of pneumonia and other infectious diseases, but which is now disappearing along with the dying school of therapeutic nihilists.

## THE ILL EFFECTS OF SMOKE.

Smoke has been indicted many times since coal as a fuel first came into use, but since manufacturing on a large scale has arisen, the evil effects of a smoke laden atmosphere have become evident. The distressing, dirty, choking fogs which are the bane of London at certain periods of the year are mainly due to the burning of soft coal for domestic use, and conditions almost as bad arising from the same cause exist in most of the cities of the Middle West.

In the *Military Surgeon*, April, 1913, Surgeon J. W. Stoner, U. S. Public Health Service, writes concerning the ill effects of smoke, and as he has lived in Pittsburgh for a year, he knows whereof he speaks. He points out that we are creatures of sunshine by nature and inheritance, and that to be deprived of sunlight is to be denied natural rights. He also traces a connection between a smoky atmosphere and drinking habits, for as he plausibly puts the case, women living in sunless, gloomy homes and attired in somber clothes are also prone to be irritable, to scold and whip their children and to greet their husbands with caustic speech, to become, in short, nagging wives. Now it is well known that no behavior is better calculated to drive a man to a saloon than nagging. Children, too, reared in a depressing atmosphere are dull, apathetic, and even criminally inclined. Not only does smoke injuriously affect the temperament of persons, but by destroying the beauties of nature, it aids in destroying the health and happiness of man.

Stoner adduces numerous statistics to prove that smoke is hurtful to health. Among these the evidence of Dr. Tatham, Medical Officer of Health for Manchester, that the working life of the Manchester people was curtailed ten years owing to the acids in smoke and its carbon particles which injure the lungs. Furthermore, in addition to destroying grass, flowers, and trees, smoke corrodes stone and tarnishes metal. However, there is little need to emphasize the point that smoke is hurtful and disagreeable from all aspects. As Stoner shows, two methods have been suggested for bringing about smoke abolition; first, by using new kinds of fuel, and, second, by improving appliances for burning bituminous coal. He advises that investigations should be made by scientists concerning the feasibility of using various proposed fuels, and in the meantime, while bituminous coal must be burned, laws should be enacted compelling more careful stoking and proper air admission to better equipped furnaces, and in some instances the introduction of smoke-consuming devices.

After all the prevention of the nuisance occasioned by smoke should rest with the health authorities, who everywhere should have power to compel manufacturers and householders alike so to restrict the output of smoke that it will be neither hurtful to health nor a source of discomfort to the public. The abatement of smoke is an important municipal problem.

### Chronic Farcy

This affection in man is notably obscure in character. A patient suffers with chronic invalidism and the frequent appearance of superficial purulent affections along with disease of the osseous and muscular system. The specific *cachet* is very elusive, and one would say at first sight that the man was a chance victim of several coincident affections, based upon a greatly diminished resistance to disease. The subject may or may not have been exposed to horses, and a search for the *Bacillus mallei* may end with negative results. At a recent session of the Royal Imperial Society of Physicians of Vienna (*Berliner klinische Wochenschrift,* May 5) Stein reported one of these mysterious cases. The patient was from Constantinople, and presented at first only serpiginous ulcers on the legs, chronic in course. Along the borders of these sores small pustules were visible. From these pus could be squeezed, but under the microscope none of the familiar pus exciters were seen. The ulcers all healed under ordinary local treatment, after which some of the bones and joints became involved. One of the knee joints filled with pus, which, however, revealed no pus-exciting germs. Some of the bones showed subperiosteal abscesses. Fever was pronounced, diazo reaction was positive. The urinary finds suggested amyloid degeneration of the kidneys. The patient succumbed, and all that autopsy showed was comprehended under ordinary septicopyemia. However, cultures revealed the presence of the *Bacillus mallei,* and the diagnosis was confirmed by animal experiment. Farcy thus considered shows a notable parallelism with swine erysipelas which behaves either as a general sepsis or a local joint affection.

---

### Orthodontia and Orthopedia.

More than a few thinkers must have been struck with the resemblance between these two disciplines, and with the propriety of studying them side by side. Yet in book and periodical literature we discover no evidence of such a tendency. The United States is the cradle of both of these sciences, yet what comity has ever existed here between our orthopedic and dental sciences? This omission has been rectified in Germany, for at a recent session of the Berlin Orthopedic Society (*Berliner klinische Wochenschrift,* May 5) a paper was read on orthodontia and was discussed freely by the membership. What, if any, relations exist between poorly implanted teeth and skeletal subdevelopment? The author of the paper, having heard the discussion, closed the latter as follows: The relationship between rickets and dental anomalies has never been finally determined. Patients reach the dentist as a rule much too late for an analysis of the relationship. The common opinion is that "open dentition" is an expression of rickets. The orthopedists and orthodontists should get together to solve the problem. Correct alignment of the teeth, considered as a rule only in connection with youth, is in reality indicated at all ages. The author has endeavored to straighten the teeth of a woman aged sixty. The main point to consider is whether the jaw is still capable of modification. If it be not, the age to cease efforts is about twenty-two or twenty-three. Modern orthodontia has reached such a high state of development that improvement in the alignment of the teeth may be effected at any age.

## News of the Week.

**Bar Friedmann Treatment.**—The Board of Health of New York City, at a meeting held on May 29, adopted a resolution constituting an amendment to the Sanitary Code, the immediate effect of which was the closing of the Friedmann Institute in this city. The adoption of the amendment followed a meeting of the Advisory Board of the Board of Health at which the latter was recommended to take action. The resolution and its preamble read in part as follows: "*Whereas* certain tests of the efficiency and safety of an alleged cure for tuberculosis now being made in this city are now being rendered unsatisfactory, unscientific and practically futile through the insistence of the originator of the alleged remedy on conditions which involve inadequate observations, inaccurate methods of administration and the insistence on secrecy regarding the substances employed in some phases of the treatment, and *Whereas* evidence is already at hand to show that the so-called remedy not only does not fulfil the promises of efficiency and safety under which its use was at first permitted in this city, but on the contrary during its administration many patients have suffered serious and unduly rapid progress of their disease, therefore be it *Resolved,* That the use of living bacterial organisms in the inoculation of human beings for the prevention or treatment of disease shall be and hereby is prohibited in New York city until after full and complete data regarding the method of use, including a specimen of the culture and other agents employed therewith, and a full account of the details of preparation, dosage and administration shall have been submitted to the Board of Health and until permission shall have been granted in writing for the use of the same."

Another of Friedmann's patients died recently, making the sixth to succumb.

**Cartwright Prize.**—Announcement is made of the awarding of the Cartwright Prize of the Association of the Alumni of the College of Physicians and Surgeons, New York, for 1913 to Capt. Edward Bright Vedder, Medical Corps, United States Army, stationed at Manila, for his essay on "Beri-beri." Capt. Vedder is a graduate of the Medical Department of the University of Pennsylvania, Class of 1902.

**Pensions for Rockefeller Institute Workers.**—Pensions for its Members and Associate Members have been provided by the governing boards of The Rockefeller Institute for Medical Research, and have been financially secured by the generosity of Mr. John D. Rockefeller, who has, with this purpose in view, increased the endowment of the Institute by a gift to it of securities amounting to about $500,000 in value. The pension rules which have been adopted provide three-quarters-pay pensions for Members of the Institute retiring at the age of 65 after 15 or more years of service, and pensions of from one-half to three-quarters of full pay, according to the length of service, for Members and Associate Members who retire at 60 years of age. There is also a provision for total disability after ten years of service, and for widows and orphaned children, at one-half the scale upon which Members of the staff are pensioned.

**Honors to Medical Men.**—The list of King's birthday honors, published June 2, contains the names of two prominent medical men. Dr. W.

Arbuthnot Lane, who recently performed two operations on the Duchess of Connaught, is made a baronet; and Professor Edward A. Schaefer, President of the British Association for the Advancement of Science, and well known for his researches in physiology, is knighted.

**New Health Society.**—The Urania Preventorium Society of New York City, organized to work for the prevention and suppression of tuberculosis, was incorporated at Albany, on May 29. The society aims to supply healthful employment to persons with tuberculous tendencies or conditions.

**New Flower Hospital.**—The cornerstone of the new building for the Flower Hospital, New York, was laid on May 29, at Eastern Boulevard and Sixty-third Street. When the building plans are completed the structure just begun will form the north wing of a three-sided quadrangle. It will be a six-story, brick building, and will be used entirely for private patients.

**Typhoid Vaccination Ordered.**—At a recent meeting of the Board of Directors of the Mount Sinai Hospital it was decided that all members of the house staff, nurses, orderlies, laundresses, and attendants, must submit to immunization by means of typhoid vaccine. For the last few years the nurses have been asked to submit to the procedure voluntarily, but only few have done so. It is now compulsory for all the hospital attendants.

**Smallpox on Battleship.**—The discovery of a case of smallpox on board the battleship *Wisconsin* on May 30, while the vessel was at the Philadelphia navy yard, made it necessary to quarantine and vaccinate all the three hundred men of the crew.

**Hospital Addition.**—The new four-story building which has just been added to the Beth Israel Hospital, New York, at a cost of $125,000, was formally opened on June 1. The building has accommodation for eighty patients, and contains operating rooms, an *x*-ray room and a laboratory.

**Medical Graduates.**—Thirty-one young men received diplomas and the degree of doctor of medicine from the Medical Department of the University of Arkansas at the thirty-fourth annual commencement exercises of the university on May 15.

**Faculty Changes.**—The Boston University School of Medicine announces a number of changes in its Faculty. After many years of service, Dr. John H. Payne, professor of ophthalmology, and Dr. Nathaniel W. Emerson, professor of gynecology, have resigned their chairs and have been made professors emeritus. Dr. David W. Wells will succeed Dr. Payne, and Dr. R. Southwick will take the place of Dr. Emerson. Mr. Everett W. Burdett, for some years lecturer on medical jurisprudence, has been made professor of that subject, and the Faculty will be further increased by the addition of the following associate professors: Pathology, Dr. Howard W. Nowell; Diseases of the Chest, Dr. Percy G. Browne; Diseases of the Nose and Throat, Dr. N. H. Houghton; Venereal Diseases, Dr. O. B. Sanders. The postgraduate summer school will be directed for the coming session by Dr. David W. Wells.

**For Medical Education.**—The Trustees of Vanderbilt University of Nashville, Tenn., have recently received from Mr. Andrew Carnegie an offer of a gift of $1,000,000 for the benefit of the Medical Department of the University. Of this sum, $200,000 will be given outright immediately to provide for the erection and equipment of new laboratories for the school, while the remainder will form a fund, the income of which will be used for its maintenance. The only condition of the offer, it is said, is that the direction of the Medical Department be committed to a board of seven members, three of whom must be eminent in medical and scientific work or research.

**Membership in the College of Surgeons of America.**—Since the organization meeting of the College of Surgeons of America, many inquiries have been received as to the method of procedure required to attain fellowship in this organization.

To the fifteen surgeons comprising the Board of Regents, representing territorially all sections of the North American continent, has been entrusted the delicate task of formulating a membership plan, to include the reception of applications for membership and the final election to fellowship in the College of those fulfilling the standard of requirements. The founders of the College conferred upon the Board of Regents almost unlimited freedom of action in carrying out this preliminary work.

While it is true that three classes of surgeons were declared eligible to election to fellowship in the College immediately, the resolutions dealing with each of these classes provided that each individual thus named shall be confirmed by the Regents before he can be formally declared a Fellow of the College.

These three groups include the surgeons and men practicing surgical specialties who have been in the practice of their specialty for a considerable length of time and who are recognized as surgeons of established reputation. They are divided for convenience into three classes: Class A, men who were chosen to organize the College by the Committee on Foundation; Class B, surgeons who are members of one of the fifteen national organizations of surgeons and surgical specialties which are designated as constituent societies; Class C, surgeons of prominence not included in Class A and not affiliated with any of the societies represented in Class B.

For Class D, which will include all other candidates, namely, young men recently graduated in medicine who wish to practice surgery as a specialty, and men who have been in the practice of medicine for a longer period and are desirous of developing a surgical specialty, a special committee of the Board of Regents is carefully preparing a standard of requirements for admission, and this plan will be presented for the approval of the Governors at the November meeting.

Of the A, B, C and D classes of members, the first three classes will be subject to consideration during the next six months, and while the men in these classes have been declared eligible to immediate membership, the Board of Regents has taken measures to subject these names to the same careful scrutiny that will be employed in the selection of members from Class D.

No man will come before the Board of Regents for final election to fellowship until the applicant has made a formal statement in writing that he is desirous of becoming a member, such application to be accompanied by the membership fee.

Surgeons representing Classes A, B and C will receive notice that they are eligible under the by-laws, and on request will be sent blanks upon which they can make their applications.

Surgeons who come under Class D, and in this class is included all legalized practitioners who are desirous of becoming members, will be furnished blanks by the Secretary upon which they may make their applications, which in due time will be carefully considered by the Board of Regents.

It is the desire of the present Board of Regents to establish the precedent that any applicant for fellowship in the College will receive the fullest consideration.

Finally, when a surgeon's original application has been passed upon favorably by the Committee on Credentials, he will be sent a fellowship blank upon which he may make his declaration of acceptance of the principles of the College, together with such other data and information as the Regents may require as a matter of record. The applicant will then be duly elected by the Board of Regents a Fellow of the College of Surgeons of America.

**English Birth Rate.**—During the first quarter of 1913, there occurred in England and Wales, 216,330 births. This total corresponds to an annual rate of 23.8 per thousand of population, which is the lowest on record for any first quarter of the year.

**Gifts to Charities.**—By the will of the late Mrs. Caroline Neustadter of New York, a large number of charities are benefited. Mount Sinai Hospital receives $100,000; the Jewish Children's Sanitarium, $50,000; the Montefiore Home and the New York Infirmary for Women and Children, $10,000 each; and St. John's Guild and the Ladies' Auxiliaries of the Monefiore Home and Mount Sinai Hospital, $5,000 each. The Children's Hospital and the Women's Hospital of San Francisco also receive $5,000 each. In addition to these bequests the sum of $1,000,000 is set aside for the foundation and maintenance of a vacation home for the poor, convalescents, and persons in delicate health, to be known as the Henry Neustadter Home.

**Obituary Notes.**—Dr. Eugene F. Hoyt of New York, a graduate of the Hahnemann Medical College and Hospital, Philadelphia, in 1870, and a member of the American Institute of Homeopathy and of the New York State Homeopathic Medical Society, died, after a short illness, in Newark, N. J., on May 26, aged 66 years.

Dr. John A. Conrad of Robesonia, Penn., a graduate of the Long Island College Hospital, Brooklyn, in 1867, and formerly a member of the Pennsylvania State Legislature, died at his home on May 12, aged 70 years.

Dr. Abel S. Cloud of Kiowa, Kan., a graduate of the University of Louisville Medical Department, in 1868, died at Cherokee, Okla., on May 10.

Dr. Peter A. Sheley of Louisville, Ky., a graduate of the Medical College of Ohio, Cincinnati, in 1876, died at his home, after a long illness, on May 12, aged 62 years.

Dr. George W. McElvern of Detroit, Mich., a graduate of the Baltimore University School of Medicine in 1885, died at his home on May 11, aged 53 years.

Dr. Solomon Wexler Laub of Las Cruces, N. M., a graduate of the Medical Department of the Tulane University of Louisiana in 1906, and a member of the New Mexico State and Dona Ana County Medical Societies, died at Natchez, Miss., after a long illness on May 11, aged 34 years.

Dr. Joseph Tomlinson of Bridgeton, N. J., died at Philadelphia, on May 19 at the age of 58 years. He was graduated from Williams College in the Class of 1875 and from the College of Physicians and Surgeons of New York in the Class of 1878. He was surgeon to the Bridgeton Hospital and a member of the Board of Education. He was a member of the Cumberland County Medical Society, the New Jersey State Medical Society and the American Medical Association.

Dr. Reuben H. Huddleston of Miami, Fla., a graduate of the Rush Medical College, Chicago, in 1872, and a member of the Florida State and Dade County Medical Societies, died suddenly at his home on May 16, aged 74 years.

Dr. George De W. Green of Holt, Mich., a graduate of the Hahnemann Medical College and Hospital, Chicago, in 1885, died at his home after a short illness, on May 24, aged 65 years.

## Obituary.

### FREDERICK FORCHHEIMER, M.D.

CINCINNATI.

Dr. Forchheimer, who died in Cincinnati on Sunday of this week, was widely and well known as an acute diagnostician and skilful medical practitioner. He was born in Cincinnati, September 25, 1853, and studied at the Universities of Strassburg and Würzburg. His medical education was obtained at the College of Physicians and Surgeons, New York, where he was graduated in the class of 1873, when less than 20 years old. He was for twenty years Professor of the Theory and Practice of Medicine in the Medical Department of the University of Cincinnati. He was a prominent member of the Association of American Physicians and served as its president in 1910-11. He was the author of many books and contributions to periodical literature and had just completed editing a new work on the Treatment of Disease.

### OUR LONDON LETTER.

(From Our Regular Correspondent.)

ARTERIOSCLEROSIS—NEW PSYCHOLOGICAL LABORATORY—DUCTLESS GLANDS—HEALTH INSURANCE CIRCULAR—SIR C. TUPPER—SIR J. PORTER—OBITUARY.

London, May 16, 1913.

The treatment of arteriosclerosis and high tension was discussed at the Medical Society of London on April 28, when a number of different opinions were elicited and remedies recommended. The subject was opened by Dr. de Haviland Hall, who referred to the conditions of modern life increasing its strain. In diet, tea, coffee, tobacco, and alcohol were implicated and autointoxication held to play an important part. Quantity as well as quality of food ought to be considered. In advanced cases meat and soups from stock should be replaced by a milk and vegetable diet. Special directions should be given to the obese. Abstinence from alcohol, "if possible," said Dr. Hall, but surely he knows that the possibility to no slight extent depends on the decisive character of the advice given. Plenty of water, preferably distilled, consumed whether hot or cold would go far to aid the exclusion of improper drinks and supersede a resort to foreign spas. But to return to Dr.

Hall's treatment, exercise in the open air, massage, an occasional dose of blue pill or calomel and the regular employment of iodides in small doses might be necessary for years. If these were contraindicated by low tension and failing compensation, digitalis and strophanthus would be useful. Thyroid extract in small quantities had helped obese patients with high tension. Dr. Hall thought that powerful vasodilators had been too freely resorted to in forgetfulness that high pressure was nature's effort to maintain the balance of the circulation. It was refreshing to hear in these days leeches or even venesection commended in suitable cases.

Sir L. Brunton approved this and said he had regarded arterial tension too exclusively as depending on the contraction of the arterioles or capillaries, neglecting too much the viscosity of the blood as a factor in raising the pressure. In a recent case he had met with such viscosity that even on venesection scarcely any flow could be obtained, so oxygen, which was standing near, was given, and after a few inhalations a full stream was obtained—the venous condition of the blood being always more viscous than the arterial no doubt was the reason of the success.

Dr. A. P. Luff remarked that very high pressure might be present with but moderate sclerosis. The treatment was to lessen the toxins in the gastrointestinal tract by free action of the bowels and reduction of meat and alcohol. Iodides of course—no vasodilators in advanced cases.

Dr. Bezly Thorne recognized two types (1) atonic and atrophic (with low diastolic and relatively high maximal pressure); (2) hypertrophic and obliterative (with relatively high diastolic pressure and comparatively small rise of the maximal). Toxemia was a cause of both and treatment should be directed to that. Dr. T. B. Scott said there was not a normal point of pressure and a double-barreled treatment was best directed toward bracing the heart and dilating the vessels. Overwork and worry were as bad as too much food and drink. Mr. Armstrong of Buxton favored spa treatment and exercise. He urged early detection of vascular change. Dr. O. K. Williamson also urged early recognition, an occasional mercurial and iodides. He found sajodin and iodopin better borne when the potash salt disagreed. As a dilator he preferred erythrol tetranitrite. Dr. Mantle said we need try to reduce pressure solely because of a rise. Cases did best when attention was directed to the alimentary tract. Dr. Hawthorne preferred the term degeneration to sclerosis. Nitrites lessened the pressure for only very brief periods. The best drug was cream of tartar—4 to 6 doses per diem. Dr. Walter Broadbent referred to one point that had not been mentioned—heredity. Some were born with high tension, he thought, while in others the pressure could not be raised. Dr. Carr thought too much was made of high pressure—much was compensatory. Failure to reduce it was often fortunate for on a fall the patient often felt worse until it rose again. As to exercise, hill climbing was better than walking on a level or even on a gradual ascent.

In the new Psychological Laboratory, formally opened yesterday, Cambridge possesses probably the finest and most complete institution of the kind. So complete is it that a description would require more than the space at my disposal to do it justice. As one illustration I may mention that in the workshop there is a small organ bellows which is noiselessly driven by water power, and can be used in the various rooms to supply air at constant pressures for blowing wind instruments for acoustic experiments. The need of a psychological laboratory had long been felt, but it was not until 1909 that a site was offered by the university and the lecturer in experimental psychology, Dr. C. S. Myers, collected among his personal friends nearly £4,000 towards the cost of building. The university association also made grants towards its equipment. It should, however, be said that the ground had been prepared by earlier workers. In 1877 Drs. Venn and James Ward had urged the need of a psychological laboratory and the idea gradually grew and was partially met by the allotment of a small room in Sir M. Foster's physiological laboratory to Dr. W. H. R. Rivers, who was appointed lecturer in experimental psychology and the physiology of the senses. A little later larger premises were obtained until after protests against their insufficiency a site for a special building was obtained, as stated above, and the new institution, worthy of the university, erected, possessing every necessity for study and research.

Professor W. Stirling has given three lectures to to the Royal Institution on "Recent Physiological Inquiries." In the last, on Tuesday, he spoke of the dominating influence of the ductless glands. These, he said, though they affected the system more slowly than the nerves, acted on the blood through their secretions, stimulating several organs. Such was the action of the internal secretions of the pituitary body, the thyroid, parathyroid, thymus and the suprarenal glands. Disaster followed any interruption of their various functions. Suppression of these was followed by diseases, *e.g.* cretinism, dwarfism, gigantism, or other changes, while the supply of their products to the blood resulted in the reciprocity of function between different parts being maintained and harmonized.

Last week the Health Insurance Commission issued a circular dealing with the representation of insured persons, laying down the mode of election by approved societies, associations of deposit contributors and when none such society exists that the local authority and medical profession may act. Other papers and memoranda have been issued by the commissioners as to bookkeeping and other matters relating to insured persons.

Sir Charles Tupper, the distinguished ex-Premier of Canada, arrived here on the 9th inst., this being his sixty-fourth time of crossing, for he is in his 92d year. You may remember that he belongs to the profession, having taken his degree at Edinburgh in 1840. He is now probably the senior graduate of the university.

Sir James Porter, K. C. B., the Director-General of the medical department of the navy, is retiring from that office. He has only held it five years and is only 61 years old. He has a very strenuous life and these five years have been very full—seven days' hard work a week, he says. But then he enjoys hard work and what he will next do is not known to many, but it will certainly not be anything easy—nor will it be rest. He tells his friends live men must go on working—it is only the dead who rest. Well, all who know what he has done wish him just what he may enjoy. Surgeon-General A. W. May succeeds to the Director-Generalship.

Mr. William James Shone, M. R. C. S., late Royal Navy, died on the 13th inst., in his 85th year. He entered the navy in 1854, served through the Crimean war, and later in the Chinese war. During the Indian mutiny he had medical charge of the

naval brigade from his ship and was under fire on thirteen occasions. He retired from the service in 1862 and practised in Bucks, becoming brigade surgeon to the Home Counties Rifles and receiving the long service decoration.

Sir J. W. Tyler, C. I. E., late Inspector-General of Prisons in the Northwest Provinces of India, died on the 12th inst. in London at the age of 73. He went to India in 1863 as civil surgeon and was for many years in charge of different divisions. He retired in 1896 after a most successful career. He was M. D. St. Andrews 1862, F. R. C. S. Edinburgh 1863.

Lieutenant-Colonel R. Manifold Craig, R. A. M. C., died on the 5th inst. in London in his 69th year. He served in the Burmese expedition, 1886-8, as senior medical officer of the Third Brigade and was awarded the medal with clasp.

Lieutenant-Colonel A. W. Mackenzie, of the Indian medical service, retired, was found dead in his bed on Sunday morning. He was staying at Plymouth and was in his 51st year. He was in the march from Kabul to Kandahar. He served in the Mahsrod Wazeri expedition in 1881 and the Waziristan of 1894. He received the Afghan medal with clasp and bronze star, and also decorations for the above named expeditions.

## OUR BERLIN LETTER.

(From Our Regular Correspondent.)

BOVINE AND HUMAN TUBERCULOSIS—BOVINE TUBERCLE BACILLI IN CHILDREN—MUTATION FORMS OF TUBERCLE BACILLI—DIFFERENCE OF OPINION.

BERLIN, April 15, 1913.

THE old question of whether the bovine type of tubercle bacillus is as pathogenic for man as the human type has been taken up anew for discussion by the Berlin Medical Society. The debate followed the reading of a paper on this subject by von Orth on February 19. The discussion became so comprehensive that two additional meetings of the society were necessary before the discussion could be completed. Orth introduced his paper with a description of the methods of differentiating the bovine from the human type of bacilli. The most important of these methods depends upon the fact that the bovine bacilli are decidely more virulent for the rabbit. Ten per cent. of all cases of tuberculosis in children are caused by the bovine type of bacillus. Similar results on this point have been obtained in New York. Of extraordinary interest are the figures obtained by Fraser of Edinburgh, according to whom there is a distinct difference between the tuberculosis of the child and that of the adult. Among sixty-seven cases of bone and joint tuberculosis this observer found in the first five years of life the bovine type of bacillus thirty-two times out of forty-seven cases, and indeed in the first year four times in four cases, and in the second year nine times out of twelve cases. In tuberculosis in the family of the children the bovine type of bacilli was found in 29 per cent. of the cases, and in 83 per cent. of the individuals of these families there was no tuberculosis. In nurslings the bovine type of bacillus was found in seven out of twenty-seven cases of tuberculosis, while of forty-one tuberculous children that had fed upon cow's milk thirty-five had the bovine bacillus. Even though Neufeld was not able to demonstrate the undoubted presence of tuberculosis in 131 children that had been fed upon the milk of tuberculous cattle, nevertheless in 8.3 per cent. of the cases there were manifestations that could be attributed to the bovine type of bacilli. It may be concluded that these microorganisms may be dangerous to human beings, and that the negative conclusions of Kirchner and Klemperer in this respect are not justified. The entire question is complicated by the fact that there are strains of tubercle bacilli which cannot be identified as belonging to either group. These strains have assumed mutation forms. Thus Ebert found three times among seventeen children and four times among fourteen adults bacilli that could not at first be identified but that after repeated passages were found to belong to the bovine group. Animal experiments have shown that human tuberculosis may originate on the basis of a bovine tuberculosis. Orth concluded that the campaign against tuberculosis in cattle should be waged with redoubled energy.

In the discussion there took part the newly chosen municipal health officer and former director of the national health bureau, Weber, who said that the bovine bacillus is not harmless to human beings, but that this microorganism is not capable of evoking widespread human epidemics. A collective investigation was made among 687 individuals, of whom 280 were children. Among these a pure bovine infection was exceedingly rare. Of those children whose cervical glands harbored the bovine bacilli, not one developed open tuberculosis even after a period of seven years. The mutation of the one type of bacillus into the other is regarded by Weber as possible, but not as proved. In one case of surgical tuberculosis the speaker had observed the presence of the bovine bacillus unchanged for ten years. Ebert's investigations were tested in the Imperial Health Office and were not confirmed.

In reply Ebert said that the researches carried out in the Imperial Health Office were not conducted according to his directions. He regarded it as proved that there are strains of tubercle bacilli that are neither human nor bovine. In twenty cases of lupus he found such strains seventeen times. In eight cases the bovine type was apparently present but the characteristic virulence of this type was absent. In nine cases the human type was present, but without virulence. It might be concluded that there are strains that grow as human strains but that possess a bovine virulence. Eckert applied the von Pirquet test to ninety-two children. Of these, seventy reacted to both types of bacilli; twelve reacted only to the bovine type, and ten only to the human type. Orth concluded that in Germany there die annually from tuberculosis 27,200 children. If only 10 per cent. of these be estimated as having a bovine infection, this furnishes a valid basis for carrying on a strenuous campaign against the tuberculosis of cattle.

**Medical Men and Morals.**—G. Pernet points out that it is not the doctor's duty to investigate reputations; he has to investigate and treat disease. In a recent case the Lord Chief Justice pointed out that a court of law was not a court of morals. Clergymen and priests seem to be ambitious to treat disease, but that, of course, is not their function—*ne sutor*. It is well to understand that syphilis is no more sinful than measles, typhoid fever, or smallpox, and to remember that it is of vital importance to the community that syphilis should be treated quickly and adequately.—*Clinical Journal*.

5. Jackson Membrane. H. W. Baker.
6. A Case of Empyema Due to Bacillus Coli. A. L. Grover.

**1. Treatment of Laryngeal Stenosis Following Diphtheria.**—D. L. Richardson delineates a method of treatment which differs from the one usually prescribed. He believes that the presence of the intubation tube in the larynx acts as a foreign body and is capable of doing much damage, as shown by post-mortem studies. It is considered rational to do a very low tracheotomy so as to keep the tracheotomy tube as far as possible away from the larynx, especially the subglottic region. The object of these two procedures is to give the larynx rest by removing the tube and diverting the air through another channel. That is what is done in almost any other surgical procedure. Another fact also impressed the author. If the presence of the tube does injure the larynx, the sooner it is out the better, after one is satisfied by a few reintubations that there is trouble ahead. The author believes that intubation should not be prolonged more than a month unless one is satisfied that one or two more extubations will find the child able to get along without the tube. There should then be performed intermittent dilatation under direct vision until the larynx reaches about normal size and then only when stenosis develops. Dilatation is accomplished by two methods: (1) By an Otis or a Kollman straight urethral dilator. (2) By successively larger intubation tubes introduced directly and which are not left in the larynx but are taken out after a few minutes. The former method furnishes more rapid dilatation, and one can pass a stenosis that cannot be passed by a one-year tube. The Kollman dilator has the advantage of being a four-branch dilator. The intervals may be two weeks or a month. After the larynx has reached about normal size, that is, will admit a tube suitable for the child's age, the patient should be left alone unless subsequent contraction supervenes.

**2. Treatment of Chronic Stenosis of the Larynx and Trachea.**—H. L. Lynah classifies the different types of chronic stenosis of the larynx and trachea as follows: (1) The nervous type, in which fear induces a violent adductor spasm. (2) Spasm type without nervous element due to the long continued wearing of the tube. (3) The polypoid type in which there is a marked outgrowth of polypoid connective tissue at the base of the epiglottis and ventricular bands. (4) The hypertrophic subglottic type, in which the stenosis is slow and gradual, accompanied by both the inspiratory and expiratory dyspnea. (5) The cicatricial type due to traumatic pathological and surgical influence. (6) The atrophic type which occurs after long continued pressure by the dilating tubes. (7) Obstruction of the upper respiratory tract by neoplasms and the resulting contraction after their removal. In discussing the treatment the author states that the different types seldom occur singly and all require prolonged intubation to effect a cure. For the nervous and spasm types an extremely narrow-necked tube should be used, but it must have a sufficiently large lumen for the patient to get air. The purpose of this tube is to allow for play of the abductor muscles. When polypoid growths are present an extremely large head and neck tube is necessary to press out these mushy masses. For the hypertrophic type gradual dilatation with the special tubes measured in millimeters with increasing diameter should be used. The tube should dilate anteroposteriorly as well as laterally, and the author's tube of cigar shape accomplishes this purpose. The best control of telling how a case is progressing when treated by dilatation is by the absence of hemorrhage at intubation and extubation. The treatment of the cicatricial type is the same as in the case of the hypertrophic type, namely, by dilatation, though when the tracheal fistula is low a special tube, with the greatest diameter from the retention swell downward, should be used. When the case is one of chronic stenosis from long wearing of a tracheal cannula with closure of the larynx above, it should be dilated from the tracheal fistula upward by means of sounds and then a suitable dilating tube should be introduced. The atrophic types with the thick sticky mucocrusts, which obstruct the larynx after a cure has been effected, should be treated by intralaryngeal medication, internal administration of the iodides, and steam inhalations. For the persistent cough-up case, which invariably becomes a chronic one if the patient does not die of bronchopneumonia, and upon which high tracheotomy is usually performed, the author has devised a tube with the same diameter as the neck extending to the end of the tube, at which site there is a bulbous extremity which rests in the lower trachea. The only danger of these tubes is that they should not be left in longer than four days before they are changed, for the contraction about them at the cricoid level will be so great that extubation will be extremely difficult.

**4. Periodical Protein-Free Diet in Chronic Nephritis.**—H. W. Goodall has found that a protein-free diet for a continuous period of from five to ten days can be maintained without harm to the individual. With such a restriction the accumulated end products of protein metabolism in the blood are promptly eliminated, the nitrogen content of the blood falls to normal, and the kidneys and heart are given an opportunity to rest. Such a restriction may be followed by a low protein diet for a considerable period of time, even in advanced cases, without a return of the disagreeable symptoms. The following procedure, which was followed in the cases reported by the author, is advised as the dietetic treatment of chronic diseases in which there is a retention of nitrogenous end products. A protein-free diet should be given for a period of from five to ten days, according to the severity of the disease. At the end of this period amounts of protein not exceeding 60 grams daily should be added and maintained until the resulting improvement of the patient will permit of a further protein increase (up to 90 or 100 grams as a maximum) or until the signs and symptoms indicate that there is a reaccumulation of waste products. In the latter event the protein free diet should be repeated. This same procedure may be employed at intervals of not less than six or eight weeks, or a single protein-free diet may be given as often as once in seven days, without injurious effects. As a caution it is advised that the diet be given under supervision, or controlled by the urinary nitrogen.

**5. Jackson Membrane.**—H. W. Baker states that this condition is of embryonic origin. All cases showing intestinal stasis due to obstruction should be treated surgically. The membrane should be severed and all raw surfaces covered with peritoneum or omentum. In cases in which this cannot be done Lane's ileosigmoidostomy should be performed.

9 A Case of Total Deafness Following a Dose of Quinine. M. J. Ballin.
10. Gastroptosis and Coloptosis Transversa as Seen from Post Mortem Examinations. K. M. Lynch.

1. **Sequestration in General Anesthesia in the Upright Position.**—T. R. French finds that operative work in the nose and throat with the patient in the upright position can be done with more skill, with less loss of blood, and with less anesthesia than when the patient is in the recumbent position. The method consists in placing the patient upon the table for anesthetization in the recumbent position, and when the stage of excitement has passed, in converting the table into a chair and bringing the body to a sitting position. In the induction of anesthesia the use of essence of orange as a preliminary to the use of ether, makes the administration of the latter less disagreeable and greatly assists in the reduction of shock by bridging the state of excitement. The closed method of administering ether is of great value in maintaining anesthesia in long operations. In addition to this sequence and method of anesthesia the author also employs Dawbarn's method of sequestration of the limbs. This is effected by causing a congestive hyperemia of the limbs by means of inflated blood pressure cuffs about the thighs and arms, or thighs. The sequestration method in association with the upright position reduces still further the amount of the anesthetic required and the amount of blood lost.

2. **Influenzal Meningitis and Pneumonia.**—T. E. Satterthwaite reports a case of pneumonia in a male aged twenty-five years. For a week previous to the onset of pneumonia the patient had been suffering from a mild influenza. The pneumonia was ushered in with a chill and violent headache. When first seen by the author the patient was unconscious with pupils irregularly dilated and unresponsive. Large doses of bromides were given to relieve the nervous symptoms. On the second day the signs of pneumonia were easily recognized. The temperature followed the characteristic curve of lobar pneumonia. Crisis occurred on the seventh day and the patient recovered. The author states that he made the diagnosis of influenzal meningitis with pneumonia on the first day the patient was seen. It is difficult to conceive the validity of the diagnosis of influenzal meningitis in this case, inasmuch as no lumbar puncture was made. This diagnosis at best was only a presumptive one, being based entirely upon the clinical picture. The author notes that influenzal meningitis is usually ushered in by violent pain in the head, especially in the frontal region and back of the neck, facial neuralgia, and photophobia. There are apt to be also irregular contractions of the pupils, muscular spasms, hallucinations, delusions, unconsciousness, perhaps mania. At first there is a high pulse rate, perhaps with arrhythmia. In the early stages patellar or ankle reflexes are apt to be exaggerated. Later, if there is effusion into the ventricles or at the base, there are loss of these reflexes, relaxation of the pupils, stupor, and a slow pulse.

3. **The Interne Year.**—I. Dyer believes that the interne year is desirable for license if it can be made systematic, which at the present time is not probable. Therefore, any rule requiring an interne year is inexpedient, and if adopted would work a hardship on all but the graduates of a few colleges owning or controlling hospital services. There should be an attempt at the gradual standardization of hospitals to educational purposes, with the future expectation of correlating hospitals and colleges of medicine in each State. This will require extensive education of the lay community. Until such time, a fifth, practical, clinical year should be required of medical graduates, and therefore should be required by State boards of examiners. To make such a clinical year efficient, State boards of examiners should stipulate the detail and amount of practical clinical work in each branch to be certified as a part of the application for a license before the candidate is admitted to examination. Such stipulation should specify each branch of medical and surgical practice and the scope of training required.

6. **Enhancing Auditory Acuity by Psychological Methods.**—W. J. W. A. Maloney states that every case of deafness should be carefully and thoroughly examined in order to ascertain if any tones are still audible. If there are no audible tones, lip reading must be taught. If there are audible tones, a tone chart should be made. The patient should be blindfolded while the audible tones are reiterated in his ear. At first these tones must be made as loud as is necessary to make them perceptible, and later diminished in intensity according to the success of the educator. Ultimately the patient will perceive them, even when they are uttered with an intensity scarcely perceptible to the normal ear. Then when these tones are thoroughly taught, training in sound pictures, vowels, etc., of which these tones are an element, should be begun. Thenceforward it will be merely a matter of time and patience until a serviceable degree of hearing can be reestablished.

9. **Total Deafness Following a Dose of Quinine.**—M. J. Ballin reports the case of a girl sixteen years old who in the course of fifteen minutes took thirty grains of quinine. Two hours later she complained of an intense headache and severe tinnitus in both ears. There was no disturbance in coordination, but she noticed a marked diminution in her hearing which steadily grew worse, so that perception for all sounds was completely lost by the following morning. She did not seek medical aid immediately, hoping that her lost function would in time reestablish itself. Finding that she remained deaf in both ears, she consulted different aurists with the hope that something could be done for her, and finally Professor Politzer of Vienna, who, after a careful examination, pronounced her case hopeless.

10. **Gastroptosis and Coloptosis Transversa.**—K. N. Lynch concludes that gastroptosis and coloptosis are secondary conditions and not primary. The underlying cause in both conditions is a weakening and relaxation of supporting structures consequent to some wasting disease, supplemented materially in the case of the colon, and to a less extent in that of the stomach, by an actual myasthenia of their walls allowing an accumulation of their contents. The emaciation is primarily the cause of the conditions, but the establishment of a vicious cycle is likely if the prolapse interferes with the digestive function. The high percentage of the occurrence of these conditions frequently stated in the literature is not borne out by post-mortem examination.

1. **The Uses of Vaccines.**—Theobald Smith emphasizes the following points: All parasites tend to increase

the resistance of the host in which they live and multiply. Out of this universal fact a number of practical problems arise. In any given disease is it worth while to try to raise this immunity, and how much energy will it cost the patient? If worth while, what is the best and most sparing way of raising such immunity artificially? In any localized infection one must ask: Is this a beginning process without attendant immunity, or is it a residual process associated with general immunity? If the latter, vaccines may be considered safe. In processes associated with fever and bacteriemia, science says, hands off until we know whether we have a progressive disease with gradual undermining of the resistance or a more localized affection in which the excursions into the blood are secondary. In any event, the use of vaccines in these cases must be regarded as experimental, and should not be undertaken without the aid of one trained in immunological problems. Judged from this point of view, as well as from the work of the laboratory as a whole, the author concludes that vaccines applied during disease will be rarely, if ever, life-saving, but they may hurry a stationary or languid process which tends toward recovery, by bringing into play the unused reserves of various tissues.

3. **Speech without a Larynx.**—E. W. Scripture states that audible speech can be taught to persons without communication between the organs of speech and the lungs and he has had opportunity recently to carry speech development in such cases much further than has heretofore been reported. The patient came to him three months after the removal of the larynx for cancer. Breathing was performed through a tracheal cannula. The method of producing the sounds of the different letters is described in detail, the principal one being the use of air taken into the mouth and expelled by the different organs, tongue, lips, teeth, etc., in different positions. For example, to produce the explosive "p." the patient was taught to close his lips and compress the air in his mouth and pharynx by tension on the cheeks and in the back of the throat. On opening the lips there was a puff and explosion of the air, producing an audible "p." For "t" he placed the point of the tongue against the palate and compressed the air in the mouth and pharynx: on releasing the tongue a distinct "t" was produced, etc. The use of the air from the tracheal cannula, which when expelled made a rushing sound, was also employed in differentiating the surds and sonants and distinguishing the vowel sounds.

9. **Transmission of Poliomyelitis.**—M. J. Rosenau notes that the chief theories to account for the spread of the disease are: (1) That it is a "contagious" disease passed directly from person to person through the secretions from the mouth and nose. (2) That it is an insect-borne disease. (3) That it is dust-borne. (4) That it is an alimentary infection, the virus being taken in with food and drink and absorbed from the digestive tract. There is evidence from the field and laboratory to support each of these theories. Infantile paralysis as an intestinal infection has not received the attention it deserves. There has been a suspicion that the disease is contracted from the lower animals, horses, dogs, etc. Its resemblance to rabies has been noted by many observers. The dust-borne theory has been given rather scant credit, as it does not have the characteristic of even air-borne infection. The insect theory, especially the part played by the stable fly, explains some peculiarities, but further experimental evidence is needed to assure one that it is the main or only source of the disorder. Among other insects the most positive evidence has been obtained from the bedbug. But a definite answer cannot be made to any of the queries suggested, and the public must be given the benefit of the doubt and the infection combated along all possible lines.

11. **Infection from a Tuberculous Attendant.**—A. F. Hess reports the instance of ten children two to three years old, in one ward of a large infant asylum, all of whom became infected with tuberculosis from an attendant who had charge of them for six weeks. The children had been subjected to a routine von Pirquet test. This was carried out throughout the hospital every six months. Three of the ten children had been found to give a positive reaction, which was accounted for in one case by the mother being tuberculous. When the nurse was found to be diseased she was discharged and the children were retested with the same results as before. Three months later all the children gave a positive reaction and three months later still the same was true. The children's health has on the whole not suffered. The author concludes that they were all infected by the attendant during a period of exposure of six weeks. A contributing cause was stomatitis, from which all the children suffered while they were under her care.

1. **Significance of Albuminuria in Pregnancy.**—H. Williamson concludes that a condition of acidosis is found constantly in cases of pregnancy toxemia when the lesions are of a certain grade of severity, and is not found in cases of chronic nephritis even when the symptoms are severe; and, further, that the onset of an acidosis in the course of a chronic nephritis in pregnancy may be interpreted to mean that toxemia has been added to the existing lesions. The author has been disappointed to find that these tests have failed in the earlier and slighter cases; in a number of instances he could find no evidence of acidosis, and in several instances in which the symptoms passed away under treatment the ammonia-urea coefficients remained normal, and acetone and diacetic acid were never demonstrated in the urine. In spite of this, however, the tests are of real clinical value. The author does not believe that the symptoms are due to the acidosis; indeed, these results definitely disprove this theory, because the symptoms are often present in a mild form before one can find any evidence of acidosis, but the results of treatment indicate that if one diminish the acidosis the severity of the symptoms will be alleviated. In severe cases of eclampsia improvement follows an intravenous infusion of solutions of sodium acetate and sodium bicarbonate. Some important points in treatment are emphasized: (1) In cases of pregnancy toxemia chloroform should never be administered, because the action of chloroform is to render more grave the lesions which already exist and to increase the acidosis. Ether administered by the open method is in every way preferable as an anesthetic. (2) Calomel should not be used as an aperient, for the lesions in the liver and kidney produced by mercurial poisoning are of the same nature as those of pregnancy toxemia, and it is probable that mercury even in small doses will increase the gravity of the lesions already existing. (3) For a similar reason douches of mercurial antiseptics should never be employed. (4) In all cases in which an acidosis is present an intravenous

infusion with a solution of sodium bicarbonate or sodium acetate should be practised. (5) The fat metabolism should be spared as far as possible by the administration of glucose. The author's practice has been to administer it by the rectum when vomiting is present and to give it by the mouth in the form of glucose lemonade where the digestive functions are not deranged. (6) When a pregnant woman suffering from chronic nephritis shows evidence of the existence of acidosis, the uterine contents should be evacuated without delay, for with a kidney previously damaged the prognosis of pregancy toxemia is very grave.

4. **The Thyroid and Alimentary Toxemia.**—F. Langmead states that an important function of the thyroid is to counteract intoxication. One of the sources of this intoxication is probably the bowel. If the intoxication be proportionately great for the gland, it undergoes hyperplasia and visible enlargement. If the amount of intoxication can be lessened the extra burden is removed and the gland diminishes. This lessening of intoxication can be effected by the use of thymol and of vaccines, especially those prepared from cultures of the coliform organisms obtained from the patient's own intestinal flora.

5. **Nerve Lesions and Pathological Conditions of Blood Vessels.**—T. Wingate Todd states that the vascular symptoms so frequently associated with the sensorimotor syndrome of the affection often laconically designated "cervical rib" are probably produced by a lesion of the nerves supplying the blood-vessels of the arm. It is then obvious that the same explanation might afford a clue to the elucidation of many other obscure conditions. The mechanism of production of vascular changes in the lower limb is likely to be similar to that found in the upper limb. In view of the probable causation of vascular changes in "cervical rib" by a nerve lesion, it is possible that a similar explanation may be found to hold good for certain other diseases exhibiting pathological changes of obscure origin in the blood-vessels. No explantion will be found satisfactory if it depends on the unproven and improbable hypothesis that sympathetic fibers for peripheral vessels pass to their distribution along the trunks of the main vessels.

1. **The Internal Secretions in Relation to Dermatology.**—Sir Malcolm Morris has found that the administration of thyroid extract is often followed by improvement in psoriasis, alopecia, ichthyosis, and xerodermia. In patients suffering from chronic skin affections of which the causation is not known, if the thyroid appears on palpation to be smaller than normal, the use of thyroid extract is suggested. In no skin affection has thyroid mediation given better results than in psoriasis. Obstinate cases of pruritus have proved amenable to its influence. Other diseases in which thyroid is of benefit are cheloid, warts, acne vulgaris, rhinophyma, lupus vulgaris, affections of the nails, and pigmentary disturbances of the skin. Neither thymus nor pituitary nor supraneal preparations have yet been extensively used in dermatology. But the author has employed thymus gland extract with advantage in acne associated with enlarged thyroid and rapid heart, and has had encouraging results from pituitary gland extract, and also from suprarenal extract, in persistent urticaria and angioneurotic edema. He has also found benefit to follow the use of suprarenal extract in lupus erythematosus, possibly owing to its influence upon the vasomotor centers.

2. **The Early Diagnosis of Gastric Carcinoma.**—T. J. Horder emphasizes three points: (1) The incidence of this disease is high; (2) the question of curability is probably in large degree a matter of early diagnosis; (3) the differential diagnosis between cancer of the stomach and other important, but less serious, maladies is often extremely difficult. One important fact is frequently elicited from the history: dyspepsia has arisen, as it were, in the midst of health; the patient is not, as a rule, a chronic dyspeptic. Anorexia is an extremely common symptom. Flatulence and heartburn are symptoms common to various stomach disorders, and to some that are trivial in their nature. They help little in the diagnosis of the case. There is, however, one point worth mentioning—that the feeling of distention, in the case of cancer, is but little relieved by careful choice of food. Pain is a very variable feature, perhaps the most variable of all. Occasionally it is quite absent, even throughout the whole illness; it is sometimes a matter for surprise to see a patient with a large gastric tumor and extreme wasting quite free from pain. Unfortunately the contrary is the rule; cancer of the stomach is usually a very painful malady. Vomiting is a variable symptom but is more constantly present than in ulcer. The vomiting of a large quantity of recently clotted blood is distinctly uncommon in cancer of the stomach. When it occurs it is often a terminal event. Loss of weight and loss of strength are significant symptoms. Careful inspection of the abdomen reveals asymmetry, and the effect of respiration upon the lines of the abdomen. Pyloric cancer leads to dilatation of the stomach. Palpation is no less important than inspection. Palpation possibly discovers five things: (1) The position and size of the stomach if this is dilated; (2) the presence of a tumor; (3) rigidity of muscles; (4) tenderness; and (5) enlarged glands or secondary masses in other organs than the stomach. The general signs of gastric carcinoma include anemia, fever, and cachexia.

6. **Chronic Arthritis and Streptococcal Infection.**—D. W. Carmalt Jones makes a contribution to the bacteriological diagnosis of arthritis based on the results of empirical therapeutic measures. He presents the records of twenty consecutive cases in private practice suffering from arthritis of various types, in all of which a tentative clinical diagnosis of streptococcal infection was made, and which were treated with vaccines of streptococci derived from different sources. The cases were, in the majority of instances, of long standing, they had resisted general therapeutic measures, and no source of infection was clearly indicated. Effusion into joints was rare, and the fluid when removed by puncture was invariably sterile. Blood cultures were also sterile whenever investigated. For various reasons streptococcal infections were suspected, and the patients were accordingly treated with vaccines made from streptococci obtained either from the mouth, in cases of oral sepsis, from the urine, or from the feces. Eight out of twenty unselected cases gave strong therapeutic evidence that their arthritis was due to infection by streptococci chiefly derived from some part of the alimentary tract.

## Berliner klinische Wochenschrift.

*May* 5 *and* 12, 1913.

**Treatment of Epilepsy.**—Erlenmeyer who has a private sanatorium for nervous affections, enumerates the measures which he finds of most value in epilepsy. In general, the management is depressive in character. Of first value is rest—for all who have over two attacks

weekly. Patients lie abed or recline in open air. A slight amount of activity is permitted, such as walking up an incline for an hour. Work he does not much believe in for the young epileptic, however useful it may be in psychoses. The usual dietetic restrictions are practiced, but in one place the author speaks of most cures probably in undernourished bedfast patients. It is not so much the quality of the food as overeating which is injurious. If the bowels are filled with a mixture of ordinary foods generating great quantities of gases, an attack is invited. The small, oft-repeated meal does well along with daily evacuations, and the author has little to say of intestinal autointoxication. Much stress is laid on care of the teeth, even if attacks result from dental operations. Hydrotherapy is valuable when used for a depressing effect. Both trephining, alone or with puncture of the ventricles, added, accomplish much in relieving certain cases. In epilepsy in childhood with likelihood of acute focus in the brain, a seton in the neck often renders good results. For drugs he uses the inorganic bromides, backed up to some extent with opium and chloral. He accepts salt starvation only to a limited degree. Salted fish and meat, and the like, he excludes. Bromides may replace table salt as a season to some extent. He has considerable faith in iodides in the young when he suspects active lesions (encephalitis, meningitis).

**Acute Nonpurulent Thyroiditis.**—Lublinski reviews our recent knowledge of this subject. The condition may occur in an intact or a goitrous thyroid (strumitis) and the author confines himself chiefly to the first. The picture of this is almost unmistakable. The onset is marked by high fever, malaise, headache, and local, radiating pain perceived chiefly in the ear and occiput. Examination reveals local pain and tenderness. In some cases a tracheitis is associated and dysphagia is usually present. The sympathetic plexus is often involved so that remote symptoms like ptosis may develop. The acute attack lasts probably one week, after which the symptoms become less marked. A relapse may occur if a unilateral attack is followed by one on the other side. In searching for a cause of this affection rheumatism is mostly in evidence, and there appears to be a distinct rheumatic type associated with acute articular rheumatism. Influenza, especially during epidemics, causes many cases, and the same is true of measles, but in all statistics we cannot tell how much strumitis is represented. Thyroiditis is also seen now and then with the other infectious diseases. The majority of victims are women during the reproductive cycle. Strumitis is excluded chiefly by the absence of history of a goitrous enlargement, and by the superior dimensions. The course is very different, for strumitis often ends in suppuration. The prognosis of pure thyroiditis is good, no fatal cases having yet been recorded. This statement must be carefully qualified, for in the rheumatic type fatal endocarditis might coexist. In certain cases Graves' disease appears as a sequela. Life may seem threatened in certain cases of tracheal compression, and a resection may be indicated, but it is hardly likely that strangulation would develop in such cases.

**Present Status of Treatment of Ozena.**—Prof. Moure of Bordeaux contributes an article on this subject with the subtitle "ozenous atrophic coryza." The author is a unicist, who does not restrict the term ozena to the type associated with sunken nose, which is presumably congenital. There are numerous intranasal conditions which cause an offensive odor, which are not germane to the subject; but aside from these ozena means for him any atrophying rhinitis which from its locality tends to reduce the lower and middle turbinals to a mere framework upon which dried crusts form—to be expelled every second, third, or fourth day. The atrophic condition of the turbinals causes the nasal chambers to seem much more ample than normal. The occasional complications of sinusitis may aggravate the picture, but is not essential to it; and the same may be said of pharyngitis and laryngitis with fetid crusting. Ozena, thus imagined, is curable. The author has pressed into service nearly every modern therapeutic resource—hot air, serotherapy, respiratory movements, compression, massage (douching), vibration, the use of paraffin. The complicating sinusites receive special management. The author's measures for treating ozena increase in importance from first to last; and the greatest amount of space is devoted to massage of all kinds, and the use of paraffin. Both these forms require special apparatus and technique. Douching appears to be the principal form of massage. The submucous injection of paraffin tends to prevent atrophy of the turbinals.

**Formation and Excretion of Oxalic Acid in Mankind.** Lichtwitz and Thörner have come to some varied conclusions under this heading; in most cases of icterus we find an increased content of oxalic acid in the urine, and as the choledochus becomes more and more permeable the content sinks. It thus appears, not only from the author's work, but from that of others, that oxalic acid escapes in part in the bile. When glycocoll in from 2 to 5 gm. doses is ingested the urine shows no increase in oxalic acid. Gelatine, however, increases the formation of the latter. The intestinal flora stand in some relationship with the formation of oxalic acid. In the lungs *Aspergillus niger* tends to form the latter. Roast partridge does not increase the urinary oxalic acid.

**Corpus Luteum and Pregnancy.**—Miller sums up a prolonged study of this subject as follows: There is a fixed interdependence between menstruation and ovulation. The rupture of the follicle precedes the hemorrhage by about nine days (average). As the ovum migrates along the tube, the membrana granulosa becomes changed to the corpus luteum, the latter now having been proved to be an epithelial formation, which when recent contains no fat. During gestation the corpus luteum gives almost no fat reaction, while the positive identification tests rest upon the presence of colloid drops and concrements of lime. Not until the regression of the corpus luteum do we find fat present in any significant quantity. The "yellow body" constitutes a gland of internal secretion of periodic manifestation. It is responsible for the cyclical transformation of the uterine mucosa into decidua. The ovum itself is nonparticipating here. The formation of decidua both favors nidation and protects it afterwards. Lactation atrophy of the uterus is not a reflex trophoneurosis, but is due to the absence of a corpus luteum in the puerperium. Menstruation means only a natural relief of the surcharged uterus and has no actual significance in regard to conception, and menstruation in mankind and the rut in animals constitute two different processes.

---

## Münchener medizinische Wochenschrift.

*May 6, 1913.*

**Diagnosis and Treatment of Chronic Pyloric Ulcer.**—Faulhaber sums up a long, comprehensive paper on this subject as follows: This lesion presents such a well-outlined symptom complex that in most cases diagnosis is self-made. Aside from the classical symptoms of gastric ulcer—cardialgia, hemorrhage (occult included), vomiting, etc., three other important symptoms are available, to wit, a periodicity in the symptoms, continuous hypersecretion and pylorospasm. The pylorospastic syndrome is not present in ulcers remote from the pylorus, and is pathognomonic of a lesion of the pylorus or immediately adjacent area. Pylorospasm is recognizable with certainty by the *x*-ray, as a result of the mild disturbances of motility present. Internal treatment is a failure in two-

thirds of all cases, so that surgical intervention must always be ranked among the relative indications. Elsewhere he mentions 75 per cent. of failures as the outside result of medical treatment.

**Erysipelas and Tattooing.**—Sehrwald's paper is based on the following case: A patient developed a severe erysipelas at the site of an active boil on the nape of the neck and the eruption spread rapidly over the entire trunk, head and neck, with severe constitutional symptoms. On the eleventh day it involved all at once the right shoulder, but did not extend itself continuously down the arm. Areas of skin were skipped and the disease seemed to select a tatooed patch. Now came the extraordinary manifestation. The tatooed area was made up of figures done respectively in red and blue ink. But while the latter were spared, the red ink areas were severely attacked and blebs even developed. In the meantime the continuous body of the erysipelas rash caught up with the outposts, which had pretty well faded. Unlike the latter, it showed no discrimination whatever, blue and red tattoo marks being involved alike. The main rash then subsided leaving the marks unchanged. The author's attempts to explain the initial immunity of the blue tattooed region lead to no permanent valid conclusions.

**Thyreogenous Etiology of Hemorrhagic Metropathies.**—Schrt writes exhaustively on this subject and adduces many disconnected data which seem to point to one conclusion as indicated by the title of the paper. Eclampsia is believed to be favored by hypothyroidism. Thyroid extract seems to have cured obligate sterility. Habitual abortion is common in cretinoids, and infantile uterus which also favors habitual abortion may be a phenomenon of hypothyroidism. An inference that tendency to abortion must of necessity suggest syphilis does not appear to be justified. The increased coagulability of the blood as connected with eclampsia has been attributed to thyroid insufficiency. The benefit from normal sera in the toxemia of pregnancy may be due to the thyroid secretion in the blood and not to any highly specific disintoxication. In the picture of hypothyroidism in pregnancy tetany is a feature, and this spasmophilia may stand in association with eclampsia. The two states have usually been radically separated because tetany does not affect the sensorium; but cases are now upon record which show that in the severest types of tetany consciousness is abolished. Passages are freely cited from Kocher, Jeandelize, Herthoge, Levide Rothschild, Seitz, Biedl, and other leading authorities on hypothyroidism which point clearly to a definite relationship between a great number of anomalies of the female reproductive organs and thyroid insufficiency which have commonly been connected with ovarian conditions. It will be the task of the future to reduce these relations to definite formulæ.

*May 1, 1913*

**Herpes Zoster Frontalis with Bacillary Find in the Gasserian Ganglion.**—Sunde reports this case which appears to support the contention of the remote past that zoster is an acute exanthematous infection, at least in certain forms. The discovery in 1863 by Bärensprung that it was due to some acute affection of the nervous apparatus naturally put an end to this view. Head and Campbell control records of 21 autopsies after zoster, and regard the latter as due to the presence in the blood of a neurotropic bacteriotoxin. They were unable to find any microorganisms in the lesions. Especially in the Scandinavian countries have attempts been made to find germ life in the cord, ganglia, nerve roots, etc., etc. Magnus found a diplococcus in the spinal ganglia, and this seems to have been the sole find up to the present time. The author now reports his case which came to light through an autopsy on a very old man who at the time of his death had a right herpes zoster frontalis in every way typical. There had been little time for post-mortem changes which are generally recognized as highly prejudicial to studies of bacteria in nervous tissues. The actual cause of death was double bronchopneumonia. An acute hemorrhagic gasseritis was present on the right side. Serial sections showed a multitude of Gram-positive cocci. The opposite ganglion was normal. In regard to earlier work it is a common experience to find germ life in lumbal punctates in herpes zoster, but apparently no attempts have been made to identify the bacteria.

**Anatomical Basis of Placenta Previa and Its Relationship to Therapy.**—Pankow states that we must differentiate between two forms of placenta previa, viz.: primary and secondary. In the first the ovum has been originally implanted in the lower uterine segment and in the second form very close to it. In certain cases the tissues of the isthmus uteri including the blood vessels become very friable, while there is a corresponding want of contractile power. The latter prevents the normal closure of the sinuses after delivery. From this viewpoint abdominal cesarean section is the indicated procedure. As this resource, as well as the performance of vaginal cesarean section, is coming more and more into use the child mortality is constantly falling until it is rated as 2.5 per cent.

**Hemoptysis from Perforated Aortic Aneurysm.**—Hampeln writes at length on this accident which he has witnessed some 15 times as the result of tracheal or bronchial perforation, all the cases necessarily fatal. This is, of course, one of the inevitable methods of termination of intrathoracic aortic aneurysm. But with the diagnosis established hemoptysis does not mean that the aneurysm has burst. The blood may proceed elsewhere than from the aneurysm, as an entirely independent affair, or the course of it may be a lesion due to a common cause, as etheroma of the pulmonary vessels, or the aneurysm itself still intact may cause a perforation into the pulmonary artery. In a word victims of aneurysm of the aorta may be subject to a variety of hemorrhages which do not involve perforation of the aneurysm. In ten of the fifteen cases the bleeding was protracted and of prodromal significance, and in the others copious and critical.

---

**Congenital Membrane of the Larynx.**—G. W. Badgerow reports the case of a boy, aged 6, who was sent to the author complaining of weakness of voice. On examination of the larynx a membrane was seen situated at the anterior commissure stretching between the cords, an opening only left in the posterior part of the glottis. There did not seem to be any interference with respiration.—*Proceedings of the Royal Society of Medicine.*

**Relapse in Scarlet Fever.**—Clément, Rouèche, and Sorel report two cases of scarlet fever with relapse. The secondary eruption appeared 24 and 34 days respectively after the primary eruption. The same premonitory, febrile, buccal, and pharyngeal symptoms appeared in the relapse as in the primary attack. The eruption lasted two to three days and there were no complications.—*Journal de Médecine de Paris.*

**The Study of Purgatives with the Technique of Intestinal Perfusion.**—R. Glénard studied the movements of the small intestine in the cat and rabbit while this organ was perfused through its blood-vessels with Locke's solution. In this manner the effects of various purgatives were noted. The majority of the latter stimulate the movement of the small intestine. But magnesium sulphate has an immediate paralyzing action. The effect of purgatives may be obtained if these are injected by the vascular or by the intestinal route. Sulphate of sodium injected intravenously into the rabbit affects the intestine by way of the blood and not by way of the nervous system. The intestinal movements following perfusion are much stronger in an animal that has been previously purged. The blood serum and extracts of the organs of an animal recently purged have a markedly stimulating effect upon the perfused intestine of another animal.—*Bulletin Général de Thérapeutique.*

# Insurance Medicine.

## SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

### ELEMENTARY PRINCIPLES OF LIFE INSURANCE.

(Note.—In the previous article, May 24, 1913, on the Annual Statement of Policy Values, the insurance in force in the largest companies was erroneously stated as between $100,000,000 and $200,000,000, through the omission of a cipher. The correct figures are from $1,000,000,000 to $2,000,000,000.)

*The Surplus.*—An insurance company can not claim to be in a flourishing condition and able to stand up against any shock or calamity unless it has a larger amount constantly on hand than is actually required to meet its liabilities. The individual who lives up to his last dollar, is not regarded as financially sound and courts future trouble for himself and his family. A bank without a healthy surplus would never be regarded as a fit depository by men familiar with business principles. Likewise, a life insurance company is in no position to inspire confidence as an agent to carry out the most sacred of trusts, the protection of dependents, unless it has an ample surplus to insure its ability to fulfill all contracts even though they extend many years into the future and may have to face unexpected emergencies.

In the case of the company used as an illustration in the article entitled "Annual Statement of Policy Values," it was assumed that there was a legal reserve deficit of $4,000,000, and that the accumulated reserve should amount to at least that sum to balance the deficit. If the assets were shown, however, to be exactly that amount, and no more, the company would be on the verge of bankruptcy, into which it might be plunged by losses due to depreciation in the value of securities, excessive mortality, etc., and yet the company would be declared to be legally solvent on the strength of the annual statement. To prevent such misfortune, the additional fund in addition to the legal liabilities must be maintained as a margin of safety. This fund is variously termed "surplus," "indivisible surplus," "unassigned funds," and, according to the New York law, "contingency reserve."

While most, if not all, the well-known insurance companies are conducted on wise and conservative lines, it is true, also, that new companies are being formed with slender resources and that some of those established within recent years are none too firmly entrenched. If an examiner were asked for advice on the subject, he should counsel his inquirer to use the same good judgment in selecting a company that he would employ in buying a horse or a farm and to apply only to a company known to be well managed and established.

Agents, in exploiting the merits of their respective companies, occasionally allude to the ratio of assets to liabilities, and the uninitiated might easily be mislead by the statements made. It should be borne in mind that the strength of a company depends upon the *amount* of surplus funds which it holds in addition to the legal reserve as well as upon the *percentage* which such surplus holds over and above the total liabilities. For instance, according to official statistics, a certain well known company had a surplus at the end of a certain year of nearly $8,000,000 and a ratio of assets to liabilities of 108 per cent. At the same time, a smaller company showed a surplus of 129 per cent., and yet this total surplus fund of 29 per cent. over the liabilities was less than $130,000. A still smaller company showed a ratio of assets to liabilities of 592, whereas the surplus amounted to only $21,000. A single unfortunate transaction, sudden depreciation in values or excessive mortality rate might result in a serious impairment or loss of the surplus belonging to the two companies last referred to, whereas the larger surplus of $8,000,000 would stand many hard blows. The relative strength of companies, then, must be estimated by the amount of extra funds as well as the ratio of assets to liabilities.

The assets of a company are composed of the legal reserve and the so-called surplus. The surplus funds do not represent profits, as they are made up entirely of gains and savings from the premiums paid and the interest thereon, or, in other words, of that part of the excessive payments which is retained as a contingency fund, most of the excess having been returned to the policyholders in the form of dividends. The surplus or excess funds, therefore, are themselves liabilities in the mutual and mixed companies, in the sense that they belong solely to the policyholders. They are retained according to the discretion and conservative judgment of the managing officers, as the maintenance of a surplus is not demanded by law. Safety and security depend upon the amount of these funds, as a few hundred thousand or even several millions of dollars might be lost through some stroke of mismanagement or recklessness. It is not conceivable, however, that the sufficient surplus retained by most companies could be squandered or lost, considering the requirements in the different States for annual statements and publicity of accounts as well as the scrutiny of every step of a company by its competitors and their eagerness to expose every mistake made by rivals.

The assets held by large companies are often regarded by legislators and a few other individuals as unnecessary, an abuse of power or even a menace to the community, though it is difficult for reasoning people to imagine how the accumulation of savings can do harm. At all events, the sense of security and protection enjoyed by policyholders fully justifies the plan, and as every cent of the assets in the mutual companies and the great bulk in stock companies belong to the policyholders, it is a question as to whether they should be a source of concern to outsiders as long as the laws of the State and propriety are complied with.

---

**Examiners' Fees in New Zealand.**—The New Zealand Branch of the British Medical Association, in accordance with its prescribed rules, has issued to its members a resolution to the effect that "throughout the Dominion the fee for a life insurance examination be not less than one guinea, but for the purpose of industrial assurance an ordinary certificate of health in place of the present printed form may be given for a fee of half a guinea."

**For the Medical Examiner.**—William J. Stapleton, Jr., offers the following points to medical life insurance examiners: (1) Answer all questions. (2) Give necessary details. (3) Look carefully into the habits of the applicant. (4) Show an interest in the interests of the company. (5) Answer all correspondence promptly. (6) Show as much skill as you can in diagnosing.—*Journal of the Michigan State Medical Society.*

## REPORTS OF THE TUESDAY CLINICAL CONFERENCES OF THE NEUROLOGICAL INSTITUTE OF NEW YORK.

FIRST DIVISION—DR. JOSEPH COLLINS.

**Muscular Atrophy Simulating That of Amyotrophic Lateral Sclerosis, Due to Syphilitic "Root Neuritis."**—Dr. JOSEPH COLLINS presenting the patient, who showed in addition to other symptoms a most profound atrophy of the muscles of the back and shoulders, said that at the last meeting of the American Neurological Association he had, in conjunction with Dr. Zabriskie, recorded a number of cases which had muscular atrophy as their most prominent symptom and which were dependent upon syphilitic disease of the cord, its coverings and the emerging spinal roots, the attribution of syphilis as the underlying cause being made entirely by the laboratory findings as these cases had nothing clinically characteristic of syphilis about them. At the same meeting Dr. W. G. Spiller read a paper which set forth a review of his cases of spinal disease with muscular atrophy in which he concluded that many of them recorded as examples of amyotrophic lateral sclerosis and other diseases were in reality dependent upon syphilis.

The patient is a tailor, 39 yrs. old, who had, when he was a child, a great many diseases, including meningitis, typhoid fever and almost all the reputed diseases of infancy. He seemed to have passed through these without entailing any lasting pathological condition. He was pretty well up until May, 1909. About that date he lifted a heavy bag and while doing this he felt "something tear in the heart and I thought I was gone." Two days later he complained of severe pain in the right shoulder blade and he noted he had some difficulty in raising the right upper extremity, at the shoulder, and after a few days the pain subsided, but he has never been able to raise the right upper extremity properly since that time.

Four months later, that is, August, 1909, he remarked the left shoulder and arm began to be weak and in the course of a few days he had difficulty in elevating this

FIG. I

shoulder. With the extension of the disease into the left shoulder there seemed to have been no pain and indeed, aside from the pain which he had shortly after lifting the heavy bag, there has been no pain since then. There had been no pain until four weeks before he came under our observation, which was on November 7, 1910. On that date his complaints were: (1) Cannot raise the right or left arm from the shoulder. The right has been affected

FIG. 2

for eighteen months, the left for twelve. (2) Frequent attacks of pain, apparently in the shoulder blades. The pain ascends the spine and into the occiput. These painful seizures are relieved by rubbing or squeezing, or by holding his arms above his head. (3) Does not sleep well. Is awakened from his sleep by the pain in the head, mainly in the occiput. Frequently is kept awake all night long. These are the spontaneous or voluntary statements of the patient. It is the painful attacks alone which have caused him to seek relief in the hospital. He says the weakness in the shoulder has not inconvenienced him much, he is still able to keep up his work, but the pain is too distressing.

On further questioning he says he has occasional difficulty in swallowing, and some "weakness and pain in the heart." Two weeks before admission he had some difficulty, lasting for ten minutes, during which time he could not speak properly. He could not speak the words he wanted to. In trying to relate to his relatives some account of his trouble, found the greatest difficulty for ten minutes, mispronouncing words and using others entirely out of place. This occurred again in the same day for about ten minutes, but since that time has not been bothered. Has had no difficulty in walking, and he is strong and well and weighs 154 pounds. Is able to do skillful work, garment-making, with his hands, but he has noticed that the left hand grip is getting weaker. His bladder control is good, bowels are regular. Vision is good now. When he has the severest pains he says the vision is poor in the lateral fields. This is not continued over any great length of time, however.

Physical examination at that time showed an atrophy not unlike that which exists at the present time and is best indicated by the accompanying illustrations, Figs. 1, 2, and 3. The tendon jerks all over the body were lively but there was no real pathological increase. The skin reflexes were all present and normal; the plantar reflex was of the flexor type and there was no sign of Babinski phenomena. The pupils were equal and presented a sluggish reaction to light, nevertheless they responded to light.

The condition is one that seemed to justify the statement that they were beginning Argyle-Robertson pupils. There was no disturbance of any form of sensibility.

The electrical reactions of the atrophied muscles were

Fig. 3

those of profound reaction of degeneration; that is no faradic reaction in the muscles most profoundly atrophied, weak response in those less atrophied, with typical qualitative changes in the atrophying and atrophied muscles.

The patient swallows easily and there was no disorder of speech. The blood Wassermann was weakly positive, a state which we interpret as a negative Wassermann reaction unless it is associated with symptoms that are "clinically" of a syphilitic nature.

It might be said in this connection that the patient had a chancre fifteen years ago with common cutaneous secondary manifestations. At that time he had received no systematic treatment and so far as could be learned no treatment after that time. The only indication that the disease was dependent upon a syphilosis of some nature was that the cerebrospinal fluid showed 45 lymphocytes, and excess of globulin, and with it reduced Fehlings. In other words, three of the four so-called reactions of the cerebrospinal fluid were positive.

We were suspicious that we were dealing with an amyotrophic lateral sclerosis. The distribution of the atrophy, the rapidity of its development, what seemed to be the beginning exaggeration of the tendon jerks, all seemed to suggest this diagnosis. The cerebrospinal fluid findings, however, were so suggestive of syphilitic disorder that we determined to put him on anti-syphilitic treatment; and he received at this time one intravenous injection of salvarsan. On February 25, 1911, that is, three months later, there was practically no change in his condition; blood Wassermann was still negative, cerebrospinal fluid Wassermann negative, globulin plus, lymphocytes 38, Fehling's plus.

We then lost sight of him until January 9, 1913, when he returned, saying that he was feeling well and strong, his one complaint being inability to use his arms. The general physical condition on that date was practically the same as on previous examination. Although he says he feels twitching all over his body, particularly in the muscles of the shoulders, no fibrillation is to be seen.

The most noteworthy change, however, is now found in his blood and cerebrospinal fluid, which was as follows: Serum Wassermann, plus; cerebrospinal fluid Wassermann, plus; globulin, plus; cells, 32; Fehling's reaction, plus. In other words, he presents now a most typical and characteristic serological picture of syphilis. Aside from this there is nothing requiring repetition from what has been said before relative to his physical signs. He was then given two injections of neosalvarsan and put on mercurial injections. After a month his blood Wassermann was negative. There has been no particular change in his clinical manifestations.

The interpretation to be put upon this case is that a syphilitic lesion of the nature of a root neuritis of the meninges comprising the anterior roots of the lower dorsal and upper dorsal segments of the cord has practically strangled the motor neurons going to the atrophied muscles. It is quite possible had this condition been recognized at the onset of the symptoms and the patient then put upon appropriate and active antisyphilitic treatment that the severity of the disease, at least, might have been profoundly mitigated. It is scarcely conceivable that a reparation should take place in the peripheral motor neurons that have undergone such decay as in this instance.

The case is presented, however, to substantiate the statement that many of the diseases of the spinal cord other than tabes and so-called syphilitic myelitis (Erb's type of syphilitic paralysis) are probably due to syphilitic infection.

SECOND DIVISION—DR. FREDERICK PETERSON.

**Osteitis Deformans.**—Dr. Foster Kennedy presented the following case: Miss J. C., age 26, complaining of pain and stiffness in the neck. Family history and previous history was negative. History of present condition: At the age of 11 patient began to be troubled with severe growing pains. At the age of 13 she had scarlet fever, after which there was marked enlargement of the cervical gland on both sides of the neck. At the same time was conscious of a feeling of stiffness in the neck. This sensation was progressive over a number of years and at the age of 18 she had considerable pain deeply seated in the neck, on movement. In 1910 an *x*-ray photograph was alleged to show cervical caries and she was put up in extension for some months. After which an immobilizing brace was worn up to the present time. She has had no disturbance of her sphincters, nor has there been any

Fig. 4

change in power in her arms or legs. There has been no objective sensory changes.

On examination the left pupil is seen to be slightly larger than the right; both eyeballs are over prominent. Von

Graefe sign is positive in both eyes. Pain and limitation of movements of the lower jaw, which is said to date from the time when she first began to wear her brace. Both supraclavicular fossæ are full, the left much more than the right, there being a definite feeling of hard and boney resistance in each. Movement of the cervical spine is limited to very slight power of rotation of the head to the right. An attempt at passive movement in other directions produces pain, chiefly local in character, but also radiating down the left arm. Movement is restricted but present in both dorsal lumbar vertebræ. There is no paralysis of any muscle. There are no objective sensory changes. Both superficial and deep reflexes are normal. Heart and lungs normal. The glands in the groin, the axillæ and in the posterior part of the neck are larger than normal. Cerebrospinal fluid, normal. Radiograph Fig. 4, by Dr. Lewis Cole fails to show any evidence of spinal caries. There is, however, an ankylosis between the anterior parts of the bodies of the fourth and fifth cervical vertibræ, which accounts for the symptom.

**Juvenile General Paralysis.**—Dr. PETERSON presented a patient who had been sent in with the diagnosis of cerebral tumor. The patient was a boy of 18 who had had headaches for five months with some incoordination of gait and station and some weakening of memory. The parents were Russian Hebrews and no very definite history farther than this could be elicited. The symptoms on the mental side were some failure of memory together with a feeling of well-being out of proportion to the actual disorder present, and on the physical side tremor of hands, face, tongue, the characteristic paretic speech, unequal Argyll-Robertson pupils, and much exaggerated wrist, elbow, knee, and ankle jerks, with ankle clonus. The diagnosis of juvenile general paralysis of specific origin was corroborated by positive Wassermann in the blood; and in the spinal fluid positive Wassermann, together with excess of globulin and 52 lymphocytes to the cm.

Cases of general paresis under twenty years of are are extremely rare, and are usually based upon hereditary lues. Whether the specific disease in this instance was hereditary or acquired could not be ascertained. The patient was the youngest of six children, the others being healthy.

THIRD DIVISION—DR. PEARCE BAILEY.

**Syphilitic Muscular Atrophy.**—In presenting a patient with this diagnosis, Dr. BAILEY said that local atrophy of

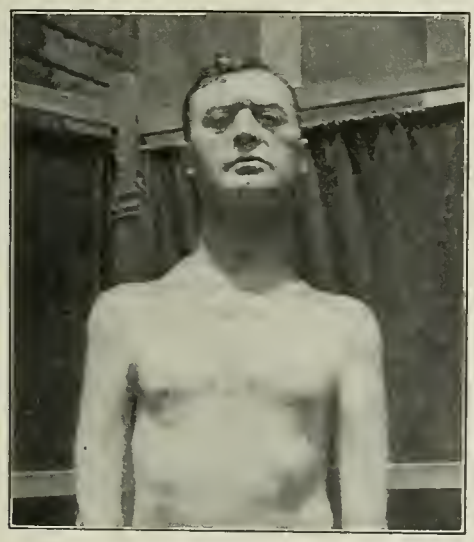

FIG. 5

spinal origin had often been noticed with syphilis as a direct cause, but in such cases the clinical course of the disease and distribution of the symptoms had usually been different from the abiotrophic forms. The course had been more or less acute and non-progressive, and had usually been associated with great pain and stiffness of the spine, suggesting a localized meningitic affection. In the case presented here, in which the evidences of intraspinal

FIG. 6

syphilis were incontestible, the course and symptoms had followed very closely those of the Duchenne-Aran type, and brought out very forcibly the necessity of determining in all cases of progressive muscular atrophy, whatever their form or course, whether or not syphilis were the exciting cause. Although in the present case the disease had existed too long to make it possible to expect much from therapeutics, it seemed reasonable to suppose that certain cases of syphilitic atrophy, if detected early, might be arrested.

Patient R. A., bookkeeper, 35 years of age, entered the Neurological Institute May 15, 1912, complaining of paralysis of the muscles of the shoulder girdle and arms. The disease had existed for nine years, during the first five of which it had been progressive, but for the past four years it had been stationary. Syphilis was denied, but, as is frequently the case in late appearing syphilis, the patient admitted having had a soft chancre fourteen years before, for which the treatment was only local. There was no history of trauma, and the patient was moderately alcoholic. Father died at 61 of apoplexy. There was no evidence in the family history of predisposition to any such disease as that from which this patient is suffering. He was well and strong as a youth. In 1894, when he was 17 years old, he began to drink very heavily. He kept this up until 1900; when he was 23 years old he took the Keeley cure. Since this he was a total abstainer for two years. Since then he has drank some, but not to excess, chiefly beer recently.

His present trouble began in 1903. At that time he was a regular in the Army. He first noticed that the biceps muscle in his right arm was growing weak. Following this the right hand would frequently tremble and shake and he found there was a certain awkwardness in using the whole upper extremity. This remained about stationary for three months, when the other muscles began to grow weak, and there was a noticeable wasting, chiefly in the arm and shoulder muscles. The condition slowly progressed, the muscles in the shoulder gradually growing more and more weak. Eight months later the left arm took identically the same course as the right had. The weakness and atrophy in this side, however, has progressed to a greater degree than the right. For the past four years there has been no increase in weakness or atrophy. He has frequently noticed fibrillary tremors in the affected muscles (these can be plainly seen now). His lower ex-

tremities were not affected until 1909; from that time until the present he finds that he tires more easily than formerly. There is a slight wasting of the left thigh and leg. He states that the right leg is decidedly stronger than the left.

Examination: There is great prominence of the lower cervical and upper dorsal spines due to falling of shoulders and weakness of trapezii. There is marked scoliosis to the right in the mid dorsal line. In the lower dorsal the spine is rigid and bends but very little below this. The muscles of the back of the neck are wasted to a very marked degree, permitting the spinous processes to be very plainly felt from the tips of the junction with the bodies. The patient carries his head with the chin well elevated and the neck arched forward in an effort to compensate for the loss of muscle support in the back of the neck.

Muscular power: The patient's arms hang by his side and he is unable to raise them except by swinging the body to one side so that the hand of the opposite side is swung past the median line and grasped by the other hand. Then by using his pectoral muscles and by swinging the arm forward he manages to bring them up so that the hands, clasped together, are thrown upon his chest. So long as he keeps them in this position he is able to use his hands for eating, shaving, etc., that is by grasping one wrist he is able to use the other hand for certain things.

Fig. 7

If he does not tightly grasp the opposite wrist both hands flop lifelessly to his side. He has absolutely no power in either biceps, deltoid or scapular muscles. Flexion and extension of the wrists only fair. Pronation and supernation are very weak in the forearm, absent in the arm. The triceps of both arms are still slightly preserved. The hand muscles of the right side are fairly strong and are not atrophied. Those of the left are atrophied and very weak. The muscular power is much better in the whole right side than in the left.

Electrical examination, May 17, 1912: The muscles of both shoulder girdles give the reaction of degeneration with the exception of the deltoids in which there is partial RD; the left side being worse than the right. Both biceps show RD. In the triceps there is marked qualitative and quantitative diminution to both the faradic and galvanic currents, but no RD. The extensors and flexors give the same reaction, but the flexors of the forearms are in better condition than the extensors. The intrinsic muscles of the right hand respond in a normal manner; those of the left hand give the reaction of degeneration. The lower limbs respond normally to both currents. The conductivity of the nerve trunks in both upper and lower extremities is normal.

Other symptoms noted were as follows: Knee jerks present, R. L.; ankle jerks present, equal. Sensory symptoms absent. There were no cranial nerve pulses, with the exception that the pupils, which were equal and 5 mm. in diameter, were sluggish to light and in accommodation. The speech was normal and there were no evidences of visceral disease.

What first attracted attention as to the possibility of these symptoms being outside the group of ordinary progressive muscular atrophy was the rather unusual distribution of the wasting and loss of power. The muscles of the shoulder girdles were affected out of proportion to those of the hands, and also the muscles were affected higher up in the neck than is usually the case in the simple progressive muscular atrophy. So that, in spite of absence of the history of syphilis or of pain in the development of the disorder, syphilis was thought of at once and the patient was subjected to serological examination. This showed a positive Wassermann in the blood, and in the cerebrospinal fluid a positive Wassermann, a positive Fehling reduction, and 16 cells per cm. With these definite evidences of syphilitic involvement of the spinal cord, salvarsan, 0.6 dram, was given intravenously on May 21 and June 7. There was no reaction from either of these injections, but after them the patient felt considerably stronger and used his legs better, so that by the middle of June he could walk further than at any time during the past three years. The shoulder muscles showed no improvement, but the forearm and arms were considerably stronger. A repetition of the serological examination on June 18th showed that the Wassermann reaction was now negative in the blood, but remained unchanged in the spinal fluid, and the cells in the spinal fluid had increased. So the most that we can infer from the effect of the treatment of this case is that the salvarsan had acted as a tonic, but had not changed the intraspinal conditions. It was repeated on June 18, after which the patient left the hospital.

This case is shown to call attention to the necessity of determining whether or not syphilis exists in all cases simulating progressive muscular atrophy.

## NEW YORK ACADEMY OF MEDICINE.

SECTION ON PEDIATRICS.

*Stated Meeting Held February* 13, 1913.

Dr. Henry Dwight Chapin in the Chair.

**A Case of Polymyositis with Multiple Lime Deposits in a Boy Five Years of Age.**—Dr. Sara Welt-Kakels presented this patient. His family history was negative, giving no indication of lues or of any hereditary nervous disposition, and no one in the family had suffered from a similar disease. The parents had been married eight years and had one other child, who was in good health. The patient was born at full term and there was nothing abnormal in connection with his birth or early childhood until his present illness, with the exception of ophthalmia neonatorum from which he recovered after a few weeks. In April, 1911, he became indisposed, lost his appetite, and suffered difficulty in walking. He could not go upstairs and walked on his toes. About three weeks after the onset of the prodromes, an exanthema appeared which was taken to be scarlatina and which lasted about eight days. The face became edematous, mainly in the palpebral region. He could not move his limbs, as both active and passive motion were very painful, especially in the joints of the back. The sensorium remained clear during his entire illness. He was entirely helpless for two weeks and confined to his bed for eight weeks. The eruption was followed by a distinct desquamation; there was, however, no exudate on the tonsils and the urine was free from albumin. He did not make a good recovery and his condition was variously diagnosed by different physicians as encephalitis, spastic paralysis, muscular dystrophy, poliomyelitis anterium, acute muscular rheumatism, toxic arthritis, and spondylitis. After treatment by a masseur the boy began to improve and the swelling in the extremities receded. During this period the boy suffered repeatedly with an itching eruption like urticaria. The patient improved for a time but in January, 1912, he again complained of pain and the former condition recurred. In

September, 1912, he was brought to the children's department of Mount Sinai Hospital. At present he was poorly nourished and there was slight elevation of the temperature. The face appeared bloated and tense and there was slight edema of the cheeks and eyelids. The pupils were equal and reacted to light; the fundi were normal. The buccal and pharyngeal mucosa were reddened; the anterior and posterior cervical gland considerably enlarged; the axillary, cubital, and inguinal glands slightly enlarged. The viscera of the abdomen and thorax were normal; the spleen was somewhat enlarged, its anterior margin being palpable. There was a urticaria-like eruption on the skin of the trunk and lower extremities. Similar eruptions repeatedly appeared and disappeared. The skeletal muscles were thin and flabby, especially on the left arm. There was motion in all joints except those of the hands, mainly the left hand. The motion of the ankle joint was slightly limited. The superficial and deep reflexes were normal, but the tendon reflexes of both upper extremities were slightly diminished. There were no facial phenomena. Electrical irritability was normal, as were also the sphincters. The left hand was considerably swollen, painful on pressure, edematous, and purplish in color. There was no pitting. The infiltration extended beyond the phalanx of the middle finger. A similar but less marked condition involved the right hand. There were three indurations in the right gluteal region which were not painful on pressure and a somewhat larger induration in the left gluteal region.

**Transfusion for Persistent Hemorrhage Following Sepsis.**—Dr. A. L. Soresi reported this case. The child was transfused last November, at which time there was running from both ears and the fingers and eyelids were purulent. The gums were soft and bleeding, and the child was found to be suffering from empyema. On account of the poor condition of the patient and a persistent cough general anesthetics could not be administered. An incision was made under local anesthesia (cocaine, 1 to 500) and pus was evacuated from the left pleural cavity. Forty-eight hours afterward the wound was still bleeding. The bleeding from the gums had increased and the child was in a desperate condition. The hemoglobin had gone down to 25 per cent. Transfusion was advised and accepted. A maternal cousin was the donor. The external jugular vein was used, as could be seen by the scar. The transfusion was stopped after six minutes when the hemoglobin had gone up to 70 per cent. The child began to improve, the bleeding stopped, and recovery followed. It was Dr. Soresi's opinion that the child's life had been saved by the prompt employment of direct transfusion.

**Remarks on the Etiology and Pathology of Hemorrhagic Disease in the Newborn.**—Dr. Oscar M. Schloss read this paper. He recalled that among the earlier writers hemophilia was considered a frequent cause of hemorrhage in the newborn, but that more recent studies had shown that most cases had no relation to true hemophilia. However, in a small group of cases, hemophilia unquestionably played an important part. These were the cases in which there was a distinct family history and in which if recovery took place the individual remained a bleeder for life. Many cases of hemorrhage in the newborn were no doubt due to bacterial infection. This view was supported both by clinical evidence and by post-mortem investigation. In a number of epidemics of hemorrhagic disease in institutions there seemed to be a direct relation between the number of cases of puerperal infection and of hemorrhage in the newborn. Finkelstein divided the cases of hemorrhage in the newborn due to bacterial infection into two groups. In the first group the pyogenic organisms were considered the causative agent. In some of these cases there was direct evidence of pus formation in connection with localized suppuration, while in others the pyogenic organism, whether alone or in connection with saprophytes, such as the *Bacillus pyocaneus* or some member of the protean group, was the supposed cause of the hemorrhage. In the second group of cases special hemorrhage-producing organisms were considered the causative agent. In most instances these organisms caused hemorrhagic forms of septicemia in animals. Bacteriological studies had yielded very inconstant results, a great number of different organisms having been isolated from the bodies of infants who had had hemorrhage during life. As most of these organisms were obtained on post-mortem examination their presence might be due to post-mortem invasion. Syphilis seemed to be an important factor in the etiology of hemorrhage in the newborn and evidence seemed to indicate that congenital syphilis caused definite vascular changes and was frequently associated with hemorrhage and that in many cases it was the only determinable factor. In addition to the general diseases there were certain local causes of hemorrhage in the newborn, such as gastric or duodenal ulcer. Chloroform poisoning had been suggested by some writers as a cause of hemorrhage in the newborn, but investigators had differed on this subject, and the final solution of the question must depend upon further study and experiment. It seemed rational to believe that the ultimate cause of bleeding was some pathological condition of the blood vessel or some defect of blood coagulation. There was no constant pathological condition of the blood in hemorrhage of the newborn. The fact that these hemorrhages were apparently due to different pathological conditions, together with the fact that investigation of the blood failed to show the presence of any uniform change forced the conclusion that the hemorrhage was merely a symptom to which there existed a predisposition during the first ten days of life. On the other hand, there was a uniform pathological condition common to all cases which was at present unknown. It was desirable that *tuba vitam* blood cultures should be made in these cases of hemorrhage in the new born, for it was only by this means that the true rôle of bacterial infection could be determined.

**Hemorrhagic Conditions in Children: Etiology, Pathology and Treatment.**—Dr. A. L. Soresi presented this communication. He said that all hemorrhagic diseases of the newborn should be grouped together under the name of hemorrhagic diathesis, because their pathology and etiology was little known and they seemed to be merely symptoms of different pathological conditions rather than distinct pathological entities. It seemed that the conditions found in the blood and blood vessels were not primary but the result of faulty general metabolism. Besides the hemorrhage, which could be called spontaneous, the blood either did not coagulate immediately as in normal conditions or did not coagulate at all. This distinguished hemorrhagic conditions from hemorrhage where the blood had a tendency to coagulate which was more marked the more severe the hemorrhage was. Of all the agents which had been thought to be the cause of hemorrhagic disease, such as syphilis, rickets, anemia, infectious diseases, faulty intestinal and hepatic function, improper food, etc., any one might be the known cause in a single case, but none of them individually, nor all together could explain the majority of cases of hemorrhagic disease. The theory that hemorrhagic disease depended on an abnormality of the capillaries had a certain anatomical basis, although there was no evidence to prove it. This did not explain the late or wanting coagulability of the blood. Whatever were the elements which retarded or prevented coagulation, it was evident that they were the result of faulty metabolism. The fact that hemorrhagic diseases were more prevalent in children seemed to show that the different organs of the body had not yet reached a harmonious collaboration between themselves and the pathology of these diseases would be clearer if they were studied together with some conditions disturbing general metabolism of adults, such as pernicious anemia, diseases of the liver, infectious diseases, chloroform poisoning, etc., in which there was a tendency to spontaneous hemorrhage and a lack of coagulability of the blood. Post-mortem findings showed only a lack of coagulability of the blood and the diagnosis in these cases was easy. Prophylaxis could do some good in hemophilia and scorbutus. Salts of calcium, styptics, and gelatin had been found of very limited value. In scorbutus and purpura change of diet and fruit juices had been found very valuable. The best and really the only effectual treatment had been what was called the physiological treatment, that was, the treatment which supplied the principles in the blood which favored coagulation and which were lacking in the patient. This physiological treatment must be considered under two different view points: First, when the patient was seen early and the only indication was to stop the bleeding, and, second, when the bleeding was very persistent and the patient had lost a great amount of blood. In the first instance horse serum and when available human serum should be employed as soon as possible. In the second instance transfusion should be resorted to as soon as possible. The injection of serum introduced thrombin into the system, which would establish the normal balance of antithrombin and thrombin or prothrombin, so that the circulating blood would be able to react normally. In some cases of hemophilia further bleeding had been stopped by applying a piece of gauze soaked with blood obtained from another person. It was evident that the injection of serum could only stop further bleeding but could not supply the morphological elements of the blood

lost through hemorrhage. As the elements favoring coagulation were at present unknown, but were all present in normal blood, it was logical to conclude that the introduction of full normal blood into the patient's system was the most rational treatment. Only one consideration could favor the use of defibrinated blood and that was if it could be proved that in defibrinating the blood new elements favoring coagulation were formed or the ones existing in the blood made more active. The strongest argument in favor of direct transfusion was that many cases had been benefited and cured by its use which had received previously all other treatments, while no case where transfusion had failed had been cured by another means. This assertion was based on an experience with 31 cases of hemorrhagic disease in the newborn, of which 28 were cured and 3 died; with 23 cases of hemophilia, of which 21 were cured and 2 died; with 6 cases of scorbutus, of which 3 were cured and 3 died; with 9 cases of purpura, of which 8 died and only 1 was cured. It could be said that in the direct transfusion of blood when properly performed surgeons had a specific remedy for hemorrhagic diseases with the exception of purpura. The idea that direct transfusion was difficult of execution had prevented this method from becoming generally applied. Transfusion should not be resorted to too late and its technique must be perfect. To avoid coagulation the greatest care must be taken not to injure the intima of the blood vessels. The author's instrument was intended to prevent this. It was composed of two little tubes crowned at one end with four hooks, held together by a little bar and screw. The blood vessels were carefully isolated, one of the tubes was passed under the blood vessel of the recipient and cuffed over the hooks; the same thing was done with the blood vessel of the donor. Both blood vessels were cut close to the edge of the cannula and put together by inserting the bar of one-half of the instrument into the corresponding hole of the other. The next important point was the selection of the blood vessels to be anastomosed. For the recipient the best was the external jugular vein; for the donor a vein of the forearm should be selected, as there was absolutely no reason for sacrificing the radial artery. Many failures were due to the fact that surgeons had not mastered their technique; therefore, no one should attempt transfusion who had not mastered the technique on living animals.

**The Treatment of Hemorrhagic Conditions by the Injection of Human Serum.**—Dr. Roger Herbert Dennett read this paper for Dr. John Edgar Welch. Dr. Dennett said that the first case of this kind which he had seen with Dr. Welch was that of a child who had had a hidden meningeal hemorrhage and was practically moribund. He was six days old and the hemorrhage had been going on for three days. Six or eight hours after the injection of human blood serum the entire condition changed, just as had been described as taking place after a transfusion. Shortly after the second injection the child began to nurse again. Lumbar puncture had been done to confirm the diagnosis of hemorrhage and pure blood was withdrawn from the spinal canal. A second lumbar puncture the day after the injection of the human blood serum showed that no hemorrhage was taking place. Dr. Dennett said he wished particularly to mention this case because it had been said that desperate cases of hemorrhage should be transfused. Dr. Soresi had mentioned that there were two great advantages in transfusion, the cessation of bleeding and the formation of new blood. Even if it were claimed that all the serum did was to stop the bleeding, it was remarkable how quickly infants seemed to be able to add to their blood supply. Dr. Welch called particular attention to the use of the serum after the hemorrhage had ceased. The more experience they had the more they favored using the serum for four or five days after the cessation of the hemorrhage. The speaker cited a case in which after the serum had been employed for two days they thought the hemorrhage had ceased and discontinued the use of the serum; on the fourth day there was a recurrence of the hemorrhage and the child died in consequence. Had they followed the rule of continuing the use of the serum for four or five days the child might have been saved. Of course, neither human blood serum nor transfusion could cure syphilis or septic infections, nor could these agents cure ulcers of the gastrointestinal tract. One could not expect human blood serum or transfusion to act as a panacea for all hemorrhagic conditions, but until these conditions were better classified they must use the human blood serum or transfusion in all cases that came along. Dr. Soresi was so proficient in transfusion work that he felt sure that he had led them to believe that the technique was easier than it really was.

**The Treatment of Hemorrhagic Conditions by the Injection of Whole Human Blood.**—Dr. Leo John Joseph Commisky read this paper in which he recalled that whole blood was first used in the treatment of hemorrhage of the newborn by Dr. Schloss in 1908 and that since that time 21 such cases and two cases of hemorrhage in older children had been treated by this method. Of this number, fifteen recovered and six died. Of the two cases of hemorrhage in older children, one a case of bleeding following the extraction of a tooth, and the other in a child suffering from erythema nodosum, who developed a purpura hæmorrhagica and bled from the mucosa of the mouth, both recovered. This group of cases included all types of bleeding and comprised among the fatal cases several which were practically moribund at the time of treatment and also several that died not on account of hemorrhage but because of an underlying septic factor. Such cases could with propriety have been omitted from their statistics, but an accurate estimate of the therapeutic value of any measure could only be made by the results from all cases. The blood was usually taken from the vein of the forearm by means of an exploratory syringe and was injected immediately into the infant's back before the blood had had time to clot. The blood was usually obtained from one of the parents or a relative. Whole blood possessed the advantages of being readily obtained, of requiring no complicated apparatus, and of being available for immediate use. As hemorrhage of the newborn was due to different pathological conditions the injection of the unchanged blood, which contained all the elements essential for coagulation, seemed to be an advantage. An objection had been raised to the use of the whole blood on the hypothesis that the cells must be broken up and excreted and in consequence put an extra strain upon the organism; in practical experience this was of no real importance. The blood was quickly absorbed, usually in from two to four hours, and for some reason did not coagulate in the tissues. Injections of whole blood had been given to feeble and premature infants with a decidedly beneficial effect and in no instance had there been any harmful influence. Injections had been given to a number of extremely marantic infants and so far as pulse, temperature, respiration, weight, and the condition of the urine was concerned there was no deviation from the previous condition. While the statistical results obtained by this method were not striking, fatal cases were included in which the method had not been given a fair trial. In a number of cases that recovered the hemorrhage was of a very severe type and the results after the use of the whole blood were most convincing. There were certain cases of hemorrhage in the newborn in which it was scarcely conceivable that any ordinary therapeutic measures could be of much benefit. It seemed improbable that the injection of whole blood or even transfusion could influence the cases of generalized bacterial infection. There was also a class of cases of profuse and rapid bleeding in which nothing except immediate transfusion could offer any hope of success. In some of the earlier cases they now believed the quantity of blood used was too small; the best results were obtained from 20 to 30 c.c. repeated every six or eight hours as long as the hemorrhage continued. Transfusion was the ideal method, but required more surgical skill than was usually available; if, however, after giving the injections a fair trial, the hemorrhage was not controlled an immediate resort to direct transfusion was indicated.

**Treatment of Hemorrhagic Conditions by Direct Blood Transfusion.**—Dr. Henry M. Lyle said that in all pathological hemorrhages the simpler method of serum and whole blood injections should be tried before resorting to blood transfusions. In severe acute hemorrhages saline infusions or blood transfusions were indicated. If the value of a procedure was measured by its simplicity, then the technique of transfusion was not ideal; direct blood vessel suture required special training and skill. The cannula method had placed in their hands a much simpler mean of transfusion. Dr. Lyle said that his experience had been limited to the use of the Crile and Elsberg cannulas and the latter had given great satisfaction. The use of fine paraffined gold tubes, as described by Carrel, was undoubtedly the simplest method. If clinical experience substantiated the promise of this procedure they would have a technique that could be performed by any physician and that was what they needed. It was now a well-established fact that severe acute cerebral anemia, though lasting only a short time, might do irreparable damage to the central nervous system. To prevent such a disaster prompt action was required and the ordinary transfusion was not practicable under such

circumstances. These patients could be resuscitated to the extent that they performed automatic functions, but the central nervous system never recovered from the cell destruction caused by the anemia, and after a longer or shorter period the automaton died, or, if he recovered, it was with a permanently damaged nervous system. This occurred most frequently in operations on small children. ordinary transfusion would not be applicable in such cases. A simple method of blood transfusion might avert such a disaster. In Bier's method of blood injections for ununited fractures, 20 to 30 c.c. of blood was withdrawn from the patient's vein and injected between the bones. The medium to prevent clotting was warm sterile salt solution. The objection to this method was the rapidity with which the blood clotted. In order to overcome his difficulty Dr. Lyle drew warm sterile liquid albolene through the needle into a Record syringe and then expressed the contents so that only a very fine film of albolene remained. In this manner 30 to 60 c.c. of fluid blood could be withdrawn and kept in the syringe for a considerable time. It might be possible to use this technique as an emergency transfusion. It seemed to the speaker that a similar method of double paraffined needles had been used or suggested in the children's service at Bellevue Hospital. Dr. Lyle presented photomicrographs of the blood of patients who had been transfused for pernicious anemia. Fifty per cent. of the leucocytes of the recipient contained red blood cells of the donor. Technically the transfusion was perfect but clinically it was a failure, the patient dying after twenty-four hours. All the biological tests were carried out before the transfusion yet they gave no indication of what followed. This case sounded a note of warning in regard to the treatment of pernicious anemia by transfusion.

Dr. George Dow Scott asked why they did not use horse serum in these cases of hemorrhagic conditions in the young, serum obtained from a young animal.

Dr. Alfred F. Hess said that he had seen a number of these cases and doubted whether blood cultures would in all cases give a proper estimate of the condition. The question arose as to whether bacteria entered the blood current after severe hemorrhage or loss of blood; in animals this did occur. It was possible that it might take place in human beings. In the cases which Dr. Schloss had reported it was not intended to state that the condition was due to bacterial infection, but that merely routine blood cultures on these cases might give a false idea of the etiology of the condition. Dr. Hess recalled a case of syphilis with marked bleeding from the nose in which transfusion was unsuccessful, although it caused an increase in the red cell count of the hemoglobin. The oozing continued and the child died; the autopsy findings were absolutely negative. Recently he had met with a similar case of syphilis in which transfusion was performed and horse serum was also employed. Dr. Hess believed that syphilis played an important rôle in the etiology of these conditions and here the injection of serum or transfusion of blood did not promise the same good results as in other conditions characterized by severe bleeding.

Dr. Herman B. Sheffield asked Dr. Soresi if transfusion was considered valuable in cases of persistent hemorrhage following circumcision.

Dr. J. Milton Mabbott asked whether at the maternity hospitals at the present time the blood naturally lost by a woman in the third stage of labor was ever used in the treatment of children suffering from hemorrhagic disease, referring of course to the children of other mothers. Could such blood which went to waste be used to furnish serum for such cases?

Dr. Oscar M. Schloss, in reply to what Dr. Hess had said about the second case, said he wished to emphasize that the point made was one they should always have in mind in taking blood cultures from autopsy material. This case was, however, an ante-mortem invasion. There were distinct endocardial invasions and as was well known these were of bacterial origin. Again an organism had been obtained which was capable of producing the condition. Dr. L. E. LaFetra had asked him to mention two cases that he had had in his service at Bellevue Hospital which he was unable to report in person. The first of these was an infant one and one-half days old who bled from the intestines and vomited large quantities of blood. When brought to the hospital the infant was cold and greatly prostrated. The pulse was barely palpable, the respirations very rapid, and the infant did not respond at all when examined. There was oozing of dark blood from the anus and this blood did not coagulate. Thirty c.c. of whole blood from a normal adult, not of the same family, were administered. The next day the infant was jaundiced but no free blood appeared in the stools and no blood was vomited. The stools were slightly tarry. Forty c.c. placental blood serum were then given and three weeks later 20 c.c. of the mother's blood was administered. From that time no more blood appeared and the infant made a good recovery. The second case was that of a boy seven years of age, with purpura hæmorrhagica, blood appearing not only in the skin but from the intestines as well. Human blood serum injections were given but were followed by only a slight improvement. An arm-to-arm transfusion was then done and the patient was apparently cured temporarily. In a few weeks the bleeding returned and the patient was then treated by injections of whole blood in large quantities. The child improved and the hemorrhage disappeared. After this there was another recurrence which was treated in the same manner and the condition again cleared up and there had been no recurrence.

Dr. A. L. Soresi said that he did not wish to be understood as objecting to the use of serum in these cases, but he wished to point out its limitations and inconveniences. The fact that its use must be continued for days and at times as much as 500 c.c. of serum given showed that it was inferior to direct transfusion which was done only once, and furthermore, the amount of blood from which the 500 c.c. of serum were extracted was at least 800 c.c.; this amount would be greatly superior if used by direct transfusion. At times only a few c.c. of blood was necessary in infants. The injection of whole blood was by no means a new procedure having been employed by surgeons before the aseptic era. It was abandoned because the elements of blood were very liable to be injured and when injected had to be absorbed. Having been injured they could not take up the work of general metabolism and must be eliminated, while when directly transfused the blood was intended to have its elements continue in the system of the recipient the function they were fulfilling in the system of the donor. Dr. Soresi emphasized the point that transfusion was a very simple procedure with the instrument he had just described and by using the external jugular vein for the recipient. As to the tubes invented by Tuffier of Paris, it was well to remember that Tuffier himself recommended having ready some other cannula as the bleeding was liable to clot in its passage through his tubes, and he went so far as to give a description and a picture of the Elsberg cannula. The technique lately recommended by Dr. Carrel, that of using the radial artery of the donor and a vein of the leg of the recipient, deserved special mention. It was not to be recommended in every case, but only when the external jugular was not available. He had himself very successfully used a vein of the left leg in doing a transfusion for Dr. Bainbridge at the Skin and Cancer Hospital two years ago. But to recommend its use in every case would be a great mistake. In cases where shock was present transfusion not only did not help the patient but lessened his chances of recovery; in such cases the heart should be supplied with new blood so that it could put in circulation again the blood that had accumulated in the abdominal vessels. By transfusing through the leg one only increased the already abnormal congestion in the abdominal vessels, thus making the patient worse. It was only necessary to mention that the veins of the leg in children could not be used because of their small size. Transfusion of blood should not be resorted to in cases of pernicious anemia as the disease was a manifestation of faulty metabolism causing destruction of the elements of the blood; the blood transfused underwent the same changes as the blood of the patient. With regard to the use of large quantities of horse serum, the inconveniences reported were that the serum caused hemolysis of the elements of the blood of the patient and serum sickness, and hence it had been abandoned. As to the danger of a too rapid flow of blood when using the external jugular vein, if the blood was flowing too rapidly it was only necessary to make a gentle compression on the blood vessel of the donor to regulate the flow.

Dr. Roger Herbert Dennett said that if one used a large amount of horse or other animal serum, he was likely to bring on "serum sickness," a condition which should be avoided. There were many cases of hemorrhage occurring in the newborn, as well as of hemorrhage following circumcision, which could be helped by the use of human blood serum as well as by transfusion. He had adopted the whole blood method in the last two cases which he had seen. Both children were in poor condition and after collecting blood for the preparation of the serum, he attached a syringe to the needle which still

remained in the vein of the donor and removed 10 c.c. of blood which he injected subcutaneously into the baby in order to save time while waiting for the blood serum. If the whole blood were used each time it would be necessary to tap the vein of the donor for each dose, while by collecting four or five ounces of blood at a time enough serum could be obtained to last for twenty-four hours. For that reason he chose whole blood for the first injection to be followed by the use of the serum.

Dr. Henry M. Lyle said that he could not entirely agree with Dr. Soresi's conclusions of the uselessness of Dr. Carrel's advice. In operative work one often came face to face with conditions that would necessitate the use of a vein of the leg. Another point to be taken into consideration was the liability of a weak anemic heart to acute dilatation; it would seem that if transfusions were made into the external jugular, there would be a slightly greater risk of acute dilatation and that this would occur more rapidly. A sharp lookout should be kept for this complication, and if it happened prompt mechanical treatment should be instituted. Judiciously employed transfusion was valuable; injudiciously employed it would become discredited.

# State Medical Licensing Boards.

## STATE BOARD EXAMINATION QUESTIONS.

### Medical Examining Board of Virginia.

*June*, 1912.

#### ANATOMY.

1. Name and describe the nerves which supply the eye.
2. Describe the aorta and name its branches.
3. Locate and give description of the kidney.
4. Give common characters of ribs—name and tell in what way the peculiar ribs differ from the others.
5. Name and describe the adductor muscles of the thigh.
6. Describe the ureter.

#### HISTOLOGY.

1. Name the elementary tissues of the body.
2. Name the forms of muscle and state principal location of each.
3. Give principal sources of white and red blood corpuscles.
4. Give histological structure of spleen.

#### PHYSIOLOGY.

1. Describe normal urine; giving color, specific gravity, reaction, visible contents and amount daily secreted.
2. Give amount of solids secreted daily by a healthy man. Of what do these solids mainly consist?
3. Under what conditions does albumin appear in urine?
4. Give methods of stimulating muscles to contraction.
5. What is meant by clonic and tonic contraction of muscles?
6. Name the ductless glands, giving location of each.
7. What substances must be taken into the body in order to afford proper nutrition to the cells and in what forms are these substances excreted from body after being utilized by cells?
8. Give function and location of gall-bladder and its connections with other organs.
9. What condition of the blood causes the phenomena known as dyspnea, apnea, and asphyxia?
10. As regards respiration, what is meant by tidal air? Reserved air? Residual air?

#### EMBRYOLOGY.

1. Name different types of embryonic cells. In what structures of body is each type chiefly concerned?
2. From what sources does the placenta derive its structure and what are the three functions of placenta in fetal life?

#### CHEMISTRY.

1. Name four classes of the compounds of C.
2. Tell something of Bi., naming its medicinal salts, and the preparation of the subnitrate.
3. What do you mean by proteolytic changes, and give an example.
4. Name a source of the following: (1) Myronic Acid. (2) $C_2N_2$. (3) Dextrin. (4) Paraffin.
5. Name five substances obtained from the destructive distillation of crude petroleum.
6. What are the amido acids and what is their importance?
7. In a case of infantile diarrhea how could you determine if (1) protein, (2) fats, or (3) starch were undigested by an examination of feces?
8. Give a test for (1) acetone, (2) bile pigments in urine.
9. Give the solubility or the reverse of following: (1) $AgNO_3$. (2) $Ca_3(PO_4)_2$. (3) $PbSO_4$. (4) $CaCO_3$. (5) NaCl. (6) $MgCl_2$. (7) Fe S. (8) $N_2SO_4$. (9) $NaNO_3$. (10) Zn O.
10. Give the chemical composition of average atmospheric air.
11. Name chemical constituents of urinary calculi.
12. Give chemical test for presence of morphine.

## ANSWERS.

#### ANATOMY.

1. The nerves which supply the eye are the second cranial, or optic nerve; the third cranial, or motor oculi; the fourth cranial, or trochlear; the sixth cranial, or abducens.

Second or Optic. "*Origin:* from optic tract, which arises by two roots: *Outer,* from external geniculate body, optic thalmus, and brachium of superior quadrigeminal body. *Inner,* from internal geniculate body. *Course.*—Winds across outer and anterior surfaces of crus cerebri, uniting with fellow to form optic commissure, which is bounded in front by the lamina cinerea and behind by the tuber cinereum; the nerves separate at fore part of commissure, get ensheathed in arachnoid, and pass into orbit through optic foramen above and internal to ophthalmic artery; while passing through, each receives a tube of dura mater, which divides into two, the outer piece becoming orbital periosteum, and the inner, ensheathing the nerve, joins the sclerotic in front. The nerve pierces sclerotic and choroid coats of eyeball. *Distribution.*—Expands to form retina. *Special function.*—Nerve of sight."

Third or Motor Oculi. "*Superficiol origin:* inner side of crus cerebri, just in front of pons. *Deep origin:* floor of aqueduct of Sylvius. *Course.*—Pierces dura mater to enter canal in outer wall of cavernous sinus near posterior clinoid process, lying above and internal to fourth nerve. As it passes forward to enter orbit through sphenoidal fissure, the fourth nerve and frontal branch of fifth cross and become superior to it. It divides into two branches in the fissure, which enter orbit between the heads of the external rectus, the nasal branch of the fifth lying between the two; while in cavernous sinus it communicates with cavernous plexus. *Distribution.*—Superior branch supplies superior rectus and levator palpebræ. Inferior divides into three for internal rectus, for inferior rectus, and for inferior oblique, which latter gives off short or motor root to the lenticular ganglion. *Special function.*—Motor nerve of eyeball."

Fourth or Trochlear. "*Origin—Superficial:* valve of Vieussens, just behind corpora quadrigemina. *Deep:* floor of aqueduct of Sylvius. *Course.*—Winds round outer surface of crus cerebri and pierces free border of tentorium; passes forward in outer wall of cavernous sinus below third, but enters orbit through sphenoidal fissure above and internal to the other nerves and external rectus. *Distribution.*—Enters orbital surface of superior oblique. *Special function.*—Motor nerve of superior oblique."

The sixth or Abducens Oculi. "*Origin—Superficial:* from the sulcus between the pons and medulla, anterior to the anterior pyramid. *Deep:* floor of fourth ventricle beneath fasciculus teres. *Course.*—Pierces dura mater on basilar process and grooves side of dorsum ephipii to reach cavernous sinus; lies to outer side of internal carotid, and below the other nerves. Enters orbit by sphenoidal fissure, between the heads of the external rectus, lying above ophthalmic vein. *Distribution.*—External rectus (ocular surface.)" (*Aids to Anatomy.*)

2. The aorta commences at the upper part of the left ventricle of the heart, ascends for a short distance, then arches backward and to the left, passes over the root of the left lung, then down the left side of the spinal column, passing through the aortic opening in the diaphragm, and terminating opposite the fourth lumbar vertebra, where it divides into the right and left common iliac arteries. *Branches of ascending aorta.*—Right coronary and left coronary; of *arch of aorta:* innominate, left common cartoid and left subclavian; of *descending aorta (thoracic)*: bronchial, esophageal, pericardial, mediastinal, intercostal, subcostal, and superior phrenic; *of descending aorta (abdominal)*: celiac axis, inferior phrenic, suprarenal, renal, spermatic (or ovarian), superior mesenteric, inferior mesenteric, lumbar, middle sacral, and common iliacs.

3. The kidneys are situated in the back of the abdom-

inal cavity, one on each side of the vertebral column, behind the peritoneum, and extending from the eleventh rib to the second or third lumbar vertebra. The right kidney is about half an inch lower than the left one. Each kidney is about four inches long, two inches broad, and one inch thick, and weighs about four and a half ounces. The kidneys are kept in place by their vessels, fatty tissue, and the peritoneum. The shape is characteristic. Each kidney is surmounted by the suprarenal gland, is surrounded by a capsule, and consists of a cortical and medullary portion. In the cortical portion are found the Malpighian corpuscles, which are tufts of capillaries, and are surrounded by a capsule which is continuous with the uriniferous tubule which ends in the renal papilla.

4. Each *typical rib* has a head, body, neck, angle, tuberosity, and sternal end.

The peculiar ribs are the first, second, tenth, eleventh, and twelfth.

The *first rib* has only a single facet for articulation with the first dorsal vertebra; and the tuberosity and angle are blended.

The *second rib* has the tuberosity and angle very close together, and the shaft is not twisted.

The *tenth rib* has only a single articular facet upon its heads.

The *eleventh rib* has no neck, no tuberosity, and but a single articular facet upon its head.

The *twelfth rib* has a single articular facet upon its head, and no neck, no angle, no groove, and no tuberosity.

5. The *adductor muscles of the thigh* are: Gracilis, Pectineus, Adductor longus, Adductor brevis, and Adductor magnus.

The *Gracilis* arises from the symphysis pubis and the pubic arch, and is inserted into the inner surface of the shaft of the tibia, just below the tuberosity.

The *Pectineus* arises from the iliopectineal line and is inserted into a line leading from the lesser trochanter of the femur to the linea aspera.

The *Adductor longus* arises from the junction of the crest with the symphysis of the pubic bone, and is inserted into the inner lip of the linea aspera. It is generally blended with the Vastus Internus and the Adductor magnus.

The *Adductor brevis* arises from the body and descending ramus of the os pubis, and is inserted into the line leading from the lesser trochanter of the femur to the linea aspera.

The *Adductor magnus* arises from ramus of pubic bone, ramus of ischium, and from tuberosity of ischium, and is inserted into the line leading from the great trochanter of the femur to the linea aspera.

6. The *ureter* is a tube about twelve inches long, connecting the kidney with the bladder. It enters the latter very obliquely, about an inch and a half from its fellow of the opposite side and the same distance from the beginning of the urethra. Behind the ureter are the Psoas magnus, common iliac artery and vein, sacroiliac sychrondrosis, and Obturator internus. In front are the spermatic vessels and the vessels of the colon (ascending or descending). The right ureter has the inferior vena cava at its inner side.

HISTOLOGY.

1. The *elementary tissues of the body* are: Epithelial, connective, muscular, and nervous tissues.

2. *Striated muscles* are found attached to bones. All the muscles under the control of the will are of this variety.

*Unstriated muscles* are found in the esophagus, stomach, intestines, trachea, bronchi, ducts of glands, blood-vessels, ureter, bladder.

*Cardiac* muscle is found in the heart.

3. *White blood cells* are derived from the spleen, lymph glands, lymph tissues, and bone marrow.

*Red blood corpuscles* are derived from the bone marrow and the spleen.

4. "The *spleen* is invested by a thick capsule, consisting of fibro-elastic tissue and a large proportion of visceral muscle fibres. The capsule sends trabeculæ into the interior of the organ. These are thick, and the nuclei of the muscle fibres in them stand out conspicuously in stained specimens. The bulk of the organ is deep red in color, and is called the spleen pulp. In the pulp are numerous whitish nodules, about the size of a pin's head. These nodules are composed of lymphoid tissue surrounding small arteries, and are called Malpighian corpuscles. The pulp consists of a network of fine fibres, with a number of flattened and branched cells situated on the fibres and at their crossings. In the spaces between the fibres are numerous red corpuscles, large lymphocytes, and other blood cells. Many of the red corpuscles undergo disintegration in the large lymphocytes, so that pigment, both intracellular and free, is present. An occasional giant cell of bone-marrow type is seen in the spleen pulp. The splenic artery breaks up at the hilus, and the branches pass into the interior of the organ along the trabeculæ. Passing away from the trabeculæ, their outer coat becomes surrounded at intervals by nodules of lymphoid tissue—the Malpighian corpuscles. Each corpuscle usually shows a germ center. The arteries open into capillaries, which, in turn, open into the interstices of the pulp. From the pulp spaces there open wide venous sinuses, which are encircled by fibres of the reticulum, and are lined by a very prominent endothelium. These sinuses open into the radicles of the splenic vein." (*Aids to Histology.*)

PHYSIOLOGY.

1 and 2. The urine is a fluid, of pale yellow color, acid reaction, characteristic odor, specific gravity about 1015 to 1025, and contains water and solids. The amount excreted daily is about 50 ounces; of this quantity, between 900 and 1000 grains are solids.

| SOLIDS IN THE URINE. | VOIDED PER DAY. |
|---|---|
| Organic— | |
| Urea ..... | about 500 grains. |
| Uric acid ..... | about 10 grains. |
| Hippuric acid ..... | about 6 grains. |
| Creatinin ..... | about 12 grains. |
| Extractives ..... | about 150 grains. |
| Inorganic— | |
| Sodium chloride ..... | about 150 grains. |
| Phosphates ..... | about 37 grains. |
| Sulphates ..... | about 24 grains. |
| Oxides of calcium, magnesium, sodium, and potassium..... | about 20 grains. |

3. *Albumin appears in the urine* in: Inflammation and degeneration of the kidneys; increased blood pressure in the kidneys; certain exanthemata, such as scarlet fever; following drugs, such as mercury, cantharides; pregnancy, purpura, scurvy, leukemia, anemia, and other diseases; diseases of the heart and coronary arteries.

4. Muscles may be stimulated to contraction by various stimuli: Chemical, mechanical, thermic, electric, and nervous.

5. In *tonic* muscular contraction the muscle remains for some time in a state of rigid contraction; in *clonic* contraction, the muscle alternately contracts and relaxes.

6. DUCTLESS GLANDS: (1) The *spleen;* situated in the back part of the left hypochondriac and epigastric regions, being covered by the ninth, tenth, and eleventh ribs on the left side. (2) The *thyroid;* situated on the sides and in front of the upper part of the trachea, and extending upward on each side of the larynx. (3) The *suprarenals;* situated in the back part of the abdominal cavity, behind the peritoneum, one on the upper extremity of each kidney, and slightly also on the inner and anterior surfaces. (4) The *carotid gland;* situated generally in the carotid bifurcation. (5) The *thymus;* situated in neck, and superior mediastinum, up to lower border of thyroid. (6) The *coccygeal gland,* at the tip of the coccyx. (7) The *parathyroids;* situated near the thyroid, on the posterior surface, near the junction of the pharynx and esophagus; but they are variable in position.

7. The cells of the body require: Water, inorganic salts, proteids, fats, and carbohydrates. *Water* leaves the body in the urine, perspiration, feces, and expired air. *Sodium chloride leaves* the body in the urine and perspiration. *Sodium phosphate* leaves the body in the urine, perspiration, and mucus. *Sulphates* leave the body in the urine, saliva, feces, mucus, and perspiration. *Carbonates* leave the body in the urine. *Calcium phosphate* leaves the body in the urine, feces, and perspiration. *Magnesium* and *ammonium salts* leave the body in the urine. *Nitrogen* leaves the body in the urine and feces. *Carbon* leaves the body in the urine, feces, and expired air.

8. The *gall bladder* is a reservoir for the bile. It is situated on the under surface of the right lobe of the liver, to which it is connected by vessels and connective tissue. It is also in relation with the transverse colon, the duodenum, and sometimes with the pyloric end of the stomach.

9. *Asphyxia* is due to lack of oxygen in the blood.

*Apnea* may be due to excess of any gas in the blood, or to lack of oxygen.

*Dyspnea* is due to lack of oxygen or excess of carbon dioxide in the blood.

10. *Tidal air* is the air which is inspired and expired during ordinary respiration.

*Reserve air* is the extra air which can be expelled by a forcible expiration.

*Residual air* is the air which cannot be expelled from the lungs, even by a forcible expiration.

EMBRYOLOGY.

1. The different types of embryonic cells are the epiblastic, hypoblastic, and mesoblastic.

"From the *epiblast* are developed: The epithelium of the mouth and salivary glands and the enamel of the teeth; parts of the nose, eye and ear; the nervous system, the pituitary and pineal bodies, the medulla of the suprarenal gland. From the *hypoblast* are developed: The epithelium of the alimentary canal between the pharynx and the anal canal, and of the liver and pancreas; the epithelium of the respiratory passages and lungs; the epithelium of the Eustachian tube and tympanium; the thyroid gland; the epithelium of the bladder and parts of the genitourinary tract. From the *mesoblast* are developed: The connective tissues; the muscles; the blood vessels, blood cells, spleen, and lymph nodes; the epithelium of the kidney, the cortex of the suprarenal, the epithelium of the reproductive organs, and of part of the genitourinary tract." (*Aids to Histology.*)

2. The *placenta* is developed from the decidua serotina and chorionic villi. The placenta serves as: (1) a respiratory organ, (2) an excretory organ, and (3) a means of nutrition to the fetus.

CHEMISTRY.

1. Saturated aliphatic compounds, unsaturated aliphatic compounds, carbocyclic compounds, and hetercocyclic compounds.

2. *Bismuth* is a trivalent element, with atomic weight of 208. It is classed by some writers with antimony, by others with phosphorus, and by others again with the metals, and sometimes it is placed in a class by itself. It is found free, also as the trioxide and trisulphide. It is usually contaminated with arsenic. The medicinal salts are: Citrate, bismuth and ammonium citrate, subcarbonate, subgallate, subnitrate, subsalicylate.

Bismuth subnitrate is made by the action of water on bismuth nitrate:

$$Bi(NO_3)_3 + H_2O = BiONO_3 + 2HNO_3$$

3. Proteolytic changes are changes effected in proteins during their digestion, and are caused by the action of proteolytic enzymes. Thus pepsin splits up proteins into proteoses and peptones. The change is probably associated with the addition of some molecules of water to the protein group.

4. *Myronic acid* exists in the seeds of black mustard.

*Dicyanogen* is prepared from mercuric cyanide.

*Dextrin* is derived from starch.

*Paraffin* is derived from petroleum.

5. From petroleum may be obtained: Cymogene, rhigolene, gasolene, naphtha, and benzine.

6. *Amido acids* are derived from aliphatic acids by the substitution of one $NH_2$ group for one atom of hydrogen in the hydrocarbon group. They are basic on account of the presence of the $NH_2$ group, they are also acid, because they retain the COOH group. Their importance is due to the number of physiological compounds which belong to this class; such are leucin, tyrosin, tryptophan, lysin, alanin, and ornithin.

7. If the *protcid* is undigested, casein may be present in the stools, or the latter may be excessive, formed, with a pale or white color. If *fat* is undigested, the stools may be oily or glistening, whitish or grayish in color, and fat globules or crystals may be detected. If *starch* is undigested, starch granules may be seen, and a blue reaction obtained with iodine.

8. *Test for acetone in urine.* Add a few drops of a freshly prepared solution of sodium nitroprusside, and then KOH solution; in the presence of acetone the liquid is colored ruby-red, and becomes purple if acetic acid is added in excess.

*Test for bile pigments in urine:* Put 3 c.c. of nitric acid in a test tube, add a piece of wood, and heat until the acid is yellow; cool. When cold, float some of the urine to be tested upon the surface of the acid. A green band is formed at the junction of the liquids, which gradually rises, and is succeeded from below by blue, reddish-violet, and yellow.

9. $AgNO_3$ is soluble in water. $Ca_3(PO_4)_2$ is sparingly soluble in water, but is soluble in acids. $PbSO_4$ is insoluble in water, but sparingly soluble in acids. $CaCO_3$ is insoluble in water, but soluble in hydrochloric or nitric or nitrohydrochloric acid. NaCl is soluble in water. $MgCl_2$ is soluble in water. FeS is insoluble in water, but soluble in hydrochloric or nitric or nitrohydrochloric acid. $Na_2SO_4$ is soluble in water. $NaNO_3$ is soluble in water. ZnO is insoluble in water, but soluble in hydrochloric or nitric or nitrohydrochloric acid.

10. Average atmospheric air consists of oxygen 20.9, nitrogen 79.0, and carbon dioxide 0.04 per cent.

11. *Urinary calculi* may consist of: (1) Uric acid, sodium urate, ammonium urate, calcium oxalate, calcium phosphate, ammonio-magnesium phosphate. (2) Cystin, xanthin, urates of potassium, calcium and magnesium, calcium carbonate.

12. *Test for morphine:* Add to the suspected substance a solution of neutral ferric chloride; the presence of morphine is indicated by the appearance of a blue color.

(*To be continued.*)

### OBSERVATIONS OF RESULTS FROM VACCINATION AGAINST TUBERCULOSIS.*

BY CHARLES A. JULIAN, M.D.,
THOMASVILLE, N. C.

IT is hardly necessary to detain you with a consideration of the need of more effective measures than such as have been available against infection with the bacillus of tuberculosis, this being abundantly demonstrated by the frequency with which it still occurs after 30 years of preventive efforts since we understood its source, including a general world-wide campaign against it, in which the United States alone is said to have expended nearly twenty millions of dollars in the year just past, and which shows that only from complete isolation of all cases that can spread the disease or from an effective method of prophylactic vaccination can we hope to attain the mastery over this formidable enemy of the human race.

With the announcement on May 1 of last year by Dr. Karl von Ruck of Asheville, N. C., that he had discovered and perfected a method of prophylactic immunization absolutely safe, uniformly efficient, and simple enough in its application by a single dose to make it available to any physician, you are undoubtedly familiar, and for the details I refer those who are not to the full report from his laboratory of June 1, which also appeared in the MEDICAL RECORD of August 31, 1912.

Having been associated in the practical application of this, his method, in 262 of the 339 children, reported upon by Dr. von Ruck in their preliminary and subsequent examinations, and having had them under my observation before and since by reason of their being under my medical charge in the Baptist Orphanage at Thomasville, it is my purpose to report to you my observations on the practical side, including the results of recent examinations after a period of 14 months since they were vaccinated, and to add like observations in 131 additional vaccinations made by myself since Dr. von Ruck made his first report.

The results of the biological tests and animal experiments which were supplied by Dr. von Ruck in the first series of cases are given in his publication referred to. Those obtained in the additional series vaccinated since by him and by myself will be communicated by Dr. von Ruck in a forthcoming second report. Not representing my own work, I propose to state these results here only in a general way, as they were reported to me from his laboratory, and beyond this I shall confine myself, as already stated, to the practical side in considering the influence of the method upon children who were known to have or were suspected of having acquired a tuberculous infection prior to their vaccination.

The biological and experimental studies referred to were designed to demonstrate the value of the method of quantitative demonstrations of specific protective substances as present before and after vaccination, and to show that they developed in response to the administration of the vaccine in sufficient amount to afford the desired protection, both in the human subject and in the lower animals.

To this end the blood serum of each child was examined before and after vaccination, more or less frequently, as appeared necessary, and again at varying intervals up to 16 months thereafter, the purpose of subsequent examinations being to determine how long the protection is liable to last. Of the results as obtained in my own cases by Dr. von Ruck, I can say that the reports supplied me correspond with those already published, there having been a uniform development, or, if already present, a decided increase in specific agglutinins, in the opsonic index and in the specific amboceptors as shown by complement fixation, and that in all new cases, as well as in all reexaminations the bacteriolytic power of the serum *in vitro* of each child was established without a single exception, and that this reached a maximum degree as shown by the complete disintegration of tubercle bacilli, in all cases on their first or subsequent examinations, when the latter were continued until the necessary maximum coincidence of amboceptors for the several partial antigens was in evidence.

To show also the bactericidal power of the serum in addition to its bacteriolytic action *in vitro* the contents of test tubes to demonstrate the latter were used for the inoculation of guinea-pigs, and it again appeared that with the sera of children taken before their vaccination (whether normal or tuberculous) no bacteriolytic or germicidal power was demonstrable, whereas this was obtainable with the serum of every vaccinated child.

All animals inoculated with tubercle bacilli exposed to the action of serum taken before vaccination died of tuberculosis, whereas all those inoculated with the same number and from the same culture of tubercle bacilli survived when the specimen of serum had been taken from a vaccinated child at the acme of the positive phase in which complete disintegration to the granular stage could invariably be obtained *in vitro*.

Dr. von Ruck recently informed me that in his continued experimental studies he has not failed to demonstrate the same degree of bacteriolytic and germicidal action with serum from guinea pigs, rabbits, and calves, previously immunized with his vaccine, and that such animals have invariably resisted a virulent infection.

While these biological and experimental studies are necessary to supply a scientific basis for the

*Read before the Tri-State Medical Association of the Carolinas and Virginia, Norfolk, Va., February 20, 1913.

method and are of the utmost importance in the demonstration of its value, the general practitioner who lacks experience, time, or facilities to make them himself or to observe them while conducted by an expert must take the results on faith, and unless he can have evidence which he can observe himself he would for a final conclusion of his own have to depend upon observations through years to come to convince himself that the results of the laboratory justified his faith and expectations.

Fortunately it was found that the method of protective vaccination against tuberculosis discovered by Dr. von Ruck need not be confined to individuals still free from infection, or that even demonstrable tuberculous changes in the lymph glands, lungs, and other organs are not a bar to its application. It is therefore possible to observe its influence upon previously infected or demonstrably tuberculous subjects, and I wish to invite your particular attention to my observation in such cases.

Before considering the results of vaccination in this class of cases I wish to anticipate a question that also arose in my own mind in regard to the experimental studies of Dr. von Ruck: It is this: "Why is it that the results of immunization in the animal experiments appear so uniform that, as Dr. von Ruck shows, it is possible to foretell them almost invariably before a virulent infection is made, whereas in the past and in the hands of all others they were either uniformly negative or, to say the least, contradictory, in the sense that complete protection against virulent infection of so highly a sensitive animal as the guinea pig has never before been proved?"

To this question I prefer to let Dr. von Ruck give the reply himself, as he did when I proposed it, and I quote from his personal communication to me as follows: "It is true that complete immunity in the sense of uniform resistance to virulent infection on the part of guinea pigs or other experiment animals has heretofore not been possible to prove conclusively and uniformly, the occasional successes which are recorded in the literature being so rare that the weight of authority of experimenters who observed only failures naturally prevailed. I also have in my earlier experimental studies met with more failures than successes, and I refrained from the publication of the latter because under apparently the same conditions my failures by far exceeded my positive results. But in the light of my more recent studies the explanation is easy enough, showing, as they do, that while in the past we had no guide or criterion by which we could know that the animal or the human subject had acquired the necessary degree of immunity, my demonstration of bacteriolysis *in vitro* of virulent tubercle bacilli through the action of immune serum, and my discovery of its relation to a certain coincidence of complement fixation with the several constituents of tubercle bacilli, supplied this guide in an almost unerring manner, and to such a degree that it can be known by the application of the bacteriolytic test *in vitro* to a given specimen of serum what the result of a virulent infection will be, either with bacilli acted upon by serum from the human subject or by that from animals, or with virulent tubercle bacilli for the infection of a supposedly immunized animal.

"These studies have further shown that while the degree of immunity necessary to cause a complete bacteriolytic and bactericidal effect is attainable in the human subject with a single dose given subcutaneously, this is not the case in those lower animals in which I have thus far attempted to produce it, and that individuals even of the same species show a marked difference in the time and number of doses necessary to protect. To obtain the immunity more rapidly in animals it is necessary to give the vaccine intravenously and to give large doses, but even by this method their response with a sufficient degree of specific antibodies is still comparatively slow. With the subcutaneous method of administration of my vaccine, which is a solution of the endotoxins, it requires for guinea pigs, rabbits, and calves from 8 to 16 weeks of preliminary treatment and exceptionally even longer to obtain a degree of immunity sufficient for their respective sera to cause complete bacteriolysis *in vitro* and complete destruction of virulence, and I find that this degree of immunity must be in evidence to be sure of their protection against virulent infection. With emulsions of tubercle bacilli, either my own or that of Koch, I am still awaiting its advent of such a degree of immunity after 6 months of preliminary treatment. You therefore can readily see that without this guide, spoken of in the light of the long time and the larger amount of vaccine required, failures were necessarily the rule, and the occasional or partial successes under apparently like conditions can now be explained by the difference in response in the development of a complete immunity by individuals of the same species of animals.

"The nature of the preparation in regard to its physical state and in regard to its proper content of all the bacillary constituents in an uninjured state appears likewise to make the greatest difference in the result. I have thus not as yet been able to successfully immunize an animal with the old tuberculin, or with bouillon filtré, nor have I had much better success with the several emulsions, or with partial antigens from tubercle bacilli in the form of primary or secondary nucleo proteids, or with peptone or the fatty extractives when used pure and uncombined with all others."

This explanation given by Dr. von Ruck appears to me a reasonable one, as amply explaining the difference in results in animal experimentation of the past. Observations of a similar nature heretofore published by Much appear to show that in a soluble vaccine against tuberculosis the fatty extractives are one of the several bacillary constituents that must be present if complete protection is to be afforded in the animal experiments. It is owing to the heretofore and almost insurmountable difficulty of isolating and obtaining them that emulsions of dead or living bacilli have been thought necessary for effective immunization, and there are those who contend that only a living virus could lead to such a result.

The demonstration of bacteriolysis and complete destruction of virulence *in vitro* with serum taken from children vaccinated with a single dose with Dr. von Ruck's preparation, which he was the first to accomplish, shows conclusively that his vaccine contains all the necessary bacillary constituents in solution, and it likewise removes all further necessity of search for an attenuated living virus, or in fact for a more effective preparation either for prophylactic or for therapeutic use, inasmuch as no vaccine or preparation can do more than act effectively in a single dose.

In my judgment a living virus would under no circumstances be admissible for prophylactic immunization against tuberculosis of the human subject. Though shown to have been non-virulent for

the highly susceptible guinea pigs I doubt that the non-tuberculous organism could cause its solution and the liberation of the contained endotoxins upon which the development of antibacterial immunity depends.

In the latter view I am sustained by the demonstration, in the milk of cows, of living tubercle bacilli of the human type three years after their use for purposes of immunization, a fact which may likewise supply an explanation for the apparent failures of v. Behring's Bovovaccine or the similar preparation of Koch and Schutz called Tauruman, uniformly to afford complete protection against subsequent infection of cattle with virulent bacilli of the bovine type.

Another and more weighty objection to the use of a living though apparently non-virulent virus for laboratory animals is the fact that non-virulence need not be permanent and that virulence can be restored spontaneously or by passage through a susceptible animal; and inasmuch as it is not possible to test the virulence of a given strain or culture of tubercle bacilli upon the human subject, and inasmuch as we know that the tubercle bacilli may remain living and in a state of latency with apparently no pathogenic power for long periods of time and thereafter become active and pathogenic, it would be a rash and ill-considered procedure, to say the least, to use any form or type of living tubercle bacilli upon the human subject simply because in the experiment upon an animal, tubercle bacilli of the same strain or from the same culture had failed to cause the development of manifest disease.

The technical details of the chemistry and of the method of preparing Dr. von Ruck's vaccine, the selection of cases, and its administration are also given explicitly in his first report. In the children vaccinated by me during the last year, I have found no difficulty in excluding actively tuberculous cases from the rapid method by a single dose, and in following the latter I have practically adhered to the doses administered in the series of cases vaccinated the year before under the personal supervision of Dr. von Ruck.

The doses of the undiluted vaccine established by him are for the respective ages as follows: For infants up to one year of age, 0.05 to 0.1 c.c.; aged 1 to 5 years, 0.1 to 0.2 c.c.; 5 to 12 years, 0.2 to 0.3 c.c.; older children and adults, 0.3 to 0.5 c.c.

Neither in the 262 children vaccinated in October, 1911, nor in those vaccinated by myself since, have I observed any disagreeable influence unless the local reactions at the point of injection evidenced by more or less sore arms, which occurred in the tuberculous and in almost all of those classed as probably tuberculous, might be so considered. In addition to sore arms we noted in some tuberculous children slight and occasionally moderate rises of temperature. These reactions were, however, as a rule, so mild that they were not especially noted by the children, and in this respect they compare very favorably with the reactions occurring after vaccination against smallpox or typhoid fever.

In non-tuberculous children no reaction occurred to the vaccination, nor was there anything observed in their condition thereafter which was in any way referable to it.

While my position prior to these practical observations in regard to the value of vaccination was one of faith and confidence in the assurance given me by Dr. von Ruck as to safety, I find that his statements in regard to the influence of the therapeutic action of the vaccination upon existing tuberculosis have been strictly conservative.

Beginning with children presenting symptoms suggestive of tuberculosis, including cough and rise of temperature, all these disappeared in the course of the first four months. All of the tuberculous and probably tuberculous children showed remarkable gain in weight and strength, their color appeared improved, while they became more active and more interested in the work and studies assigned to them. This general improvement was observed not only by children old enough to do so themselves, and upon special inquiry for the purpose by myself, but by all those who came into more or less frequent contact with them.

A more critical examination by myself and by Dr. Silvio von Ruck in April, 1912, of those whose record showed the presence of physical signs on the part of the lungs, enlarged lymph glands, or other tuberculous localizations prior to their vaccination, showed their complete disappearance or retrogression and with few exceptions, a most remarkable gain in body weight. The local and general improvement was so marked that an apparent recovery or at least complete arrest could have been accepted in all but a few of the more advanced cases. An exception to such a result occurred in two cases in which, in addition to pulmonary involvement, other tuberculous complications were present, consisting, in one case, of tuberculous peritonitis, in which I felt it necessary to resort to laparotomy for the evacuation of a purulent exudate; in one case of tuberculous disease of the right tibia in which I secured drainage by incision, and in a third case of Pott's disease, all of which were treated with the vaccine until their recovery which has since become complete and assured.

At the request of Dr. von Ruck a more general systematic reexamination was undertaken the latter part of last November in all cases vaccinated in 1912, their physical condition being determined by myself, while the blood examinations and animal experiments were made in Dr. von Ruck's laboratory.

The examinations on my part were finished early in December, therefore 14 months after the vaccination of the first series of 262 cases in 1911, and 3 months after vaccination of the second series of 131 children by myself.

I have already spoken of the remarkable and early general improvement of children who were classed as positively or probably tuberculous, and as this can be shown best by their increase of body weight, I regret that an actual comparison is possible only in 109 vaccinated in 1911, because there is no record of weight at the time of their preliminary examinaton for the others. I may, however, state that the comparative results shown in the 109 cases would not be liable to differ materially in the remainder, inasmuch as weights made at later periods, and the general observation on my part and on that of the others, indicate that their improvement in nutrition was equally good.

COMPARATIVE WEIGHTS IN 109 CHILDREN BEFORE AND 14 MONTHS AFTER VACCINATION.

One patient fully grown and having normal weight has neither lost nor gained. One patient likewise fully grown and of normal weight, has changed from 124 pounds recorded at the prelimi-

nary examination to 120 pounds as determined in December. Both patients give evidence of normal health. We find, therefore, that there were available for comparison 64 cases, all of which have gained.

*66 cases classed as tuberculous.*

| | Pounds | | Per cent |
|---|---|---|---|
| Minimum gain | 4 | Min. increase in body weight | 4.4 |
| Maximum " | 41 | Max. " " " " | 60.0 |
| Average " | 20 | Ave. " " " " | 26.5 |

*20 cases classed as probably tuberculous.*

| | Pounds | | Per cent |
|---|---|---|---|
| Minimum gain | 7 | Min. increase in body weight | 8.9 |
| Maximum " | 24 | Max. " " " " | 45.6 |
| Average " | 13.8 | Ave. " " " " | 24.2 |

*23 cases classed as normal.*

One child lost 2 pounds; available for comparison are 22 cases all of whom gained weight.

| | Pounds | | Per cent |
|---|---|---|---|
| Minimum gain | 4 | Min. increase in body weight | 6.6 |
| Maximum " | 24 | Max. " " " " | 31.7 |
| Average " | 8.7 | Ave. " " " " | 12.9 |

A comparison of the average gains in pounds and in percentage of the increase of body weight between the normal and the tuberculous or probably tuberculous children, showing over 100 per cent. in favor of the latter, appears to be indicative of more than a coincidence, the more so, as the conditions of diet and environment were the same for all, and also because an average gain of body weight of 25 per cent. is far beyond the normal increase for the age periods of 4 to 16 years which we can assume to be represented more correctly by the children who are classed as normal. This assumption appears to be correct on examining a detailed tabulation of each case, with intervening weight records, which on account of space cannot find room in this communication, but which shows that the excess in gain of the tuberculous occurred at an early period after their vaccination, and that their subsequent gain is not materially different from that shown for the normal children.

PHYSICAL EXAMINATION OF THE LUNGS OF 112 CASES CLASSED AS TUBERCULOUS.

In the preliminary examination of the 262 children there were 112 whose lungs presented evidence of pathological changes noted almost exclusively in children above the age of 12 years. In seven of them the presence of symptoms of marked fever or cough, or bacillary sputum or of other tuberculous localizations was considered sufficient reason for excluding them from the rapid method, and they were given smaller and increasing doses of vaccine, at intervals of five days, the number of doses varying from three to nine.

In the cases considered suitable for the rapid method with a single dose, the signs determined consisted of a more or less pronounced apical catarrh in some cases of both sides, in others only on one side, with a rough character of the inspiration, accompanied in some instances with a bronchial element and prolonged expiration. As a rule, more or less marked loss of the percussion resonance could likewise be shown in parts of the affected lung areas, and slight rises of temperature of from half to one degree, rarely more, were frequently one of the symptoms. All cases reacted to tuberculin, showed serum agglutinations, as a rule, in dilutions of 1:10 or over. Complement fixation, when trials were made, was negative. In 84 cases, palpable lymph glands of one or more groups were part of their record.

The physical signs of the lungs determined before vaccination can be grouped as follows:

| | Cases. |
|---|---|
| Signs marked in both apices and upper lobes | 32 |
| Signs marked in one apex or upper lobe, slighter in the opposite lung | 28 |
| Signs of slighter degrees, on both sides | 8 |
| Signs marked on one side only | 22 |
| Signs slight on one side only | 15 |
| Signs indicative of destructive lesion on one side, with slighter involvement on the opposite side | 5 |
| Cases considered active and progressive | 2 |

The results of the physical examinations made by me last December and therefore 14 months after vaccination corresponded in practically all the nonactive or so-called latent affections with those made last April, while in the cases classed as having destructive lesions in their lungs or otherwise pursuing an active course and in which marked amelioration and retrogression of physical signs had been found last April the evidence to this effect is now still more marked.

Excepting one case, in which other than tuberculous disease accounts for an unsatisfactory state of health, all these children are in excellent physical condition. Those who apart from their lowered state of nutrition had also shown symptoms of fever, cough, expectoration, lost them at an early period and have remained free from them ever since. In 27 cases in which the physical signs were of slight degree, nothing abnormal can now be shown by percussion or auscultation. There is no evidence of apical catarrh in any case. In instances, however, in which the physical signs were marked, some degree of diminished resonance can still be shown in small and circumscribed areas over which the respiratory sounds are not perfectly normal, the inspiratory sound being either weaker or lacking in vesicular quality and quantitatively often showing a harsh element coexisting or predominating. The other and adjacent parts which had previously given abnormal signs show now no change from normal. In quite a number of these cases there is now more or less marked subclavicular retraction, corresponding with the area of diminished resonance and of abnormal respiration which in extent is very small, as a rule, not exceeding 1 inch in diameter. I am therefore of the opinion that the present findings in all such cases are indicative of lesions which have undergone a process of healing and cicatrization, corresponding as they do with signs generally accepted as of such import, and I am the more certain that this interpretation is the correct one, inasmuch as none of them have reacted either locally or generally to a subcutaneous tuberculin test which I applied about a month ago, whereas a like test applied before their vaccination was positive in every case in which it was made.

Physically and clinically these children have all made a complete recovery after a single dose of the vaccine and, with one exception stated, they are in perfect health.

ENLARGEMENT OF LYMPH GLANDS.

In addition to the 84 children in whom physical signs of lung involvement were also present there were 82 others in whom enlargement of lymph glands was a part of their record, making a total of 166 cases. The order of frequency of involvement of the several groups was the cervical, axillary, and inguinal groups, although it should be stated that the examination of the latter was frequently omitted especially in older girls. The involvement of one or more groups was as follows: One group only, 12 cases; two groups, 97; three groups, 15; four groups, 38; five groups, 2; all six groups, 2. My records of reexamination made in December

give the following results: Not examined, 6 cases; no enlargement found in any one of the several groups previously recorded at present, 153 cases; enlarged glands found in 1 group with previous records for 4 groups, 1 case; enlargement found in 1 group with previous records for 3 groups, 1 case; enlargement in 1 group with records for 2, 2 cases; enlargement in 2 groups with records for 4, 1 case; enlargement in 2 groups with records for 2, 2 cases: total, 166 cases.

In the cases in which enlarged lymph glands could still be found, I am unable to say whether they were changed in number, size, or consistency, as the records are not explicit enough for comparison. I can, however, say that when the records were explicit and stated that they were numerous, or that they were large, I have found none at all, or but few small glands, firm and hard to the touch.

Proceeding to the results in 131 cases three months after their vaccination, the improvement of the tuberculous and probably tuberculous classes as represented by gain in body weight was found as remarkable as that shown in the preceding series of 1911.

For comparison of weights I have available records in 110 in which it is recorded before and again three months after vaccination and you will note that the increase in weight in so short a time as three months bears me out in my statement that, as in the series of 1911, the improvement in nutrition occurs at an early period after administration of the vaccine. Normal weight having been reached in the tuberculous its further increase in growing children is then the same as it is in those free from tuberculosis.

COMPARATIVE WEIGHTS IN 110 CHILDREN BEFORE AND 3 MONTHS AFTER VACCINATION.

*36 cases classed as tuberculous. All gained weight.*

| | Pounds | | Per cent |
|---|---|---|---|
| Minimum gain | 3 | Min. increase of body weight | 4.0 |
| Maximum " | 21.5 | Max. " " " " | 37.5 |
| Average " | 10.1 | Ave. " " " " | 16.1 |

*48 cases classed as probably tuberculous. All gained weight.*

| | Pounds | | Per cent |
|---|---|---|---|
| Minimum gain | 7 | Min. increase of body weight | 8.9 |
| Maximum " | 49 | Max. " " " " | 45.6 |
| Average " | 13.8 | Ave. " " " " | 13.9 |

*26 cases classed as normal. 24 gained weight (2 cases show no change).*

| | Pounds | | Per cent |
|---|---|---|---|
| Minimum gain | 1.5 | Min. increase of body weight | 1.9 |
| Maximum " | 10.5 | Max. " " " " | 15.4 |
| Average " | 3.6 | Ave. " " " " | 4.2 |

PHYSICAL EXAMINATION OF THE LUNGS IN 31 CASES CLASSED AS TUBERCULOUS.

Pathological changes as indicated by physical signs on chest examination were present in 31 cases. Of the cases classed as positively tuberculous, and, as in the series of 1911, they were found chiefly in older children between the ages of 12 and 16 years; in all of them the result of a tuberculin test prior to vaccination was positive. In 26 cases of latent or inactive lesions, including 11 cases in which slight subjective symptoms and temperature elevations between 99° and 100° were also present, only a single full dose of vaccine was given, whereas in five cases in which the affections were more advanced, because associated with marked subjective symptoms including cough, bacillary expectoration and fever, the vaccine was given in small and increasing doses.

Applying the same classification as adopted for the 1911 series, the present cases group as follows: Marked signs in both upper lobes, 2 cases; marked signs on one side, slighter on the opposite side, 8; slight signs on both sides, 2; marked signs on one side only, 12; slight signs on one side, 2; signs indicative of destructive lesions on one side with slighter involvement on the opposite side, 4; signs indicative of destructive lesions on both sides, 1—total, 31.

The result of my reexaminations made three months after vaccination show that in 10 cases all physical signs have disappeared, and in instances in which slighter signs in one lung were present with marked signs in the other, the slighter signs have also disappeared. In all the remainder, excepting 2 of the advanced cases which are still under treatment, the physical signs have receded and diminished being limited to small areas in which catarrhal signs, when previously recorded, are not now present.

The respiratory sounds are weak or lack in the unmixed vesicular element, while the percussion note is not as fully resonant as it is on the opposite side. All previously present symptoms have disappeared; the temperature is normal in all; the general condition of nutrition, strength, and sense of well being is good.

A tuberculin test previously positive in all cases classed as tuberculous or suspected to be so continues positive in 6 cases. Three of these having shown physical slight subjective symptoms, were vaccinated with a single dose, the fourth case had been further treated and has since been dismissed, and the other two are still under treatment.

ENLARGEMENT OF LYMPH GLANDS.

In addition to 8 cases among the 31 in whom physical signs of lung involvement were present, there were 32 and therefore a total of 40 cases in which enlarged lymph glands were found on preliminary examination, and, as in the series of 1911, chiefly of the cervical and axillary groups. In 2 cases all the cervical, axillary, and inguinal groups were enlarged. All of these cases gave a positive reaction to tuberculin, and represent mostly the "probably tuberculous class."

The number of groups of enlarged lymph glands was as follows: One group enlarged, 2 cases; two groups, 31 cases; four groups, 5 cases; six groups, 2 cases.

In my reexaminations I have not been able to find a single instance in which I could detect any glandular enlargement. In 15 there had been temperature elevations between 99° and 100.5° F.; reexaminations showed the temperature to be normal. None reacted to tuberculin and the general health is entirely satisfactory in every case.

This concludes the clinical evidence which I desire to submit of the value of prophylactic immunization in instances of suspected infection, as also in those cases in which the diagnosis of early stage tuberculosis was conclusively established by the usual available methods.

My observation of degrees of local and general changes for the better, with complete restoration of the general health in all cases of suspected or manifest tuberculosis, which clinicians as a rule agree to accept at least as evidence of complete arrestment if not of an apparent cure, justifies the assertion that, even from a most conservative standpoint, there has been an undoubted relation between the vaccination and the results shown, and that the method has resulted beneficially to these children in a degree and with a uniformity which we have not been accustomed to witness here-

tofore, a conclusion all the more justified by the fact that there has been no change in the mode of life, environment, or in dietetic, hygienic measures, and that no other treatment of medication designed to aid in the realization of the results has been resorted to.

Calling attention once more to the facts determined by Dr. Karl von Ruck that specific protective substances were not found in the sera of any of the children before their vaccination, excepting in comparatively few of the tuberculous cases and never sufficient to cause disintegration and destruction of virulence of tubercle bacilli, whereas after the administration of the vaccine, the presence of such protective substances was invariably demonstrable in the serum in amounts sufficient to cause complete lysis *in vitro* and complete destruction of virulence as shown by animal experiments, I believe there can be no reasonable doubt that the practical results observed by me, and the scientific experimental demonstrations by Dr. von Ruck, correspond in a striking manner and that they naturally support each other.

This being the case, and finding that after the vaccination of normal children the same protective substances appear in their sera, with the same bacteriolytic and bactericidal power, unabated in all cases reexamined at various periods up to 20 months since their vaccination, we have reached the limit of the evidence it is possible to supply, of a successful and effective vaccination. This evidence it appears to me would have been sufficient without additional proof by Dr. von Ruck that the same protection can be conferred upon guinea pigs, rabbits, calves, and sheep, which he found to respond to the vaccine by acquiring a complete resistance to virulent infection, their sera developing the same bacteriolytic and germicidal power *in vitro* that is shown in the human subject, and with the same uniformity, except that the animals did not show the same rapid response and that they required longer periods of preliminary treatment.

I forego any comment on the therapeutic possibilities of the vaccine as unnecessary in the light of the results I have shown in my tuberculous cases, especially in those which represent the early stages of the disease, in all of which a single dose proved efficient in bringing about a clinical cure.

## AMBARD'S "UREMIC CONSTANT," OR THE ESTIMATION BY MATHEMATICS OF THE FUNCTIONAL VALUE OF THE KIDNEYS.

By CECIL KENT AUSTIN, M.D.,

PARIS, FRANCE.

In an article that appeared in these columns, January 4, of the present year, I called attention to the important clinical work in the field of medical nephritis that has been carried on of late by a group of young physicians in France, under the leadership or inspiration of Widal and Castaigne; and special stress was laid on the comparatively recent idea, in this connection, of judging of the functional capacity of the kidneys by determining the percentage of urea circulating in the blood. The fact was there referred to that as a means of prognosis in nephritis this urea-percentage stands without a rival at the present time, experience having revealed that, although it is not impossible for cases of this sort to show temporary periods of remission, as a rule the length of time the patient still has to live can be foretold with almost mathematical accuracy from these figures. So great has the importance of this method been found that in a recent article Widal himself has said that if forced to choose, in making a prognosis, between the figures for the albumin in the urine and for the urea-percentage in the blood, he would unhesitatingly take the latter. In view, therefore, of the relative newness of this chapter of the nephritic subject, of its capital importance, and of the fact that it appears to have not yet entered at all into the field of practical medicine at home, it has seemed desirable to take up the subject once more, and to refer at the same time to one or two quite recent developments in the matter.

It may at first sight seem peculiar that the degree of gravity of a case of nephritis should be indicated by the percentage of urea-retention in the blood, urea itself being the least toxic among the nitrogen products of disassimilation, its molecule having a very simple formula so as to make it an easy problem for handling by the renal excretory epithelia. But in the method of determining the hematic urea-percentage the urea is simply used as an indicator, experience having shown that increase or decrease in its amount follows quite accurately the fluctuations of the other nitrogen products of disassimilation, which are believed to be the determining factors of renal insufficiency, although it is not certain which the special culprits are, the likelihood being that they all take a part in producing that condition, and that it is in reality a very complex state.

But while it has proved that an estimate of hematic urea is a safe guide as a basis for an opinion as to the gravity of a case of nephritis and its probable prognosis, longer experience has demonstrated the fact that this statement requires a slight modification. If a man were taken in full health, but a notoriously free-liver, and particularly a person addicted to flesh-eating in excess, it is fairly certain that a urea-percentage would be found with him that in a chronic renal case would indicate a prognosis of a very serious character; yet with the heavy eater it would mean nothing at all, his elimination of urea by the urine being equally high. This is equivalent to saying that one of the characters of urea-excretion by renal tubular epithelium is that the greater the amount presented for its handling by the circulation, the higher its efficiency in that particular. "Appetite comes with eating," as the expression goes. It is therefore necessary to introduce into this problem of the value of the hematic urea-percentage the factor ingesta, solids and fluids, it being manifest that a nephritic case taking the ordinary daily allowance of 100 grams of albumin will show a higher blood index than one on a partial, hyponitrogenous diet of 30-40 grams, or, *a fortiori*, than one placed for the time being on a diet from which all albumin has been eliminated.

This dependency of the urea blood index as a basis for prognosis on the nature of the patient's diet was felt to be an unquestionable flaw in the value of the method, so much so that Ambard, chief of laboratory at Necker Hospital, in this city, has been at infinite pains to elaborate a modification of the procedure that is claimed to have entirely done away with this defect, and to give results that can be altogether relied on and that are quite independent of the manner in which the patient may be living at the moment the test is made.

Ambard is a medical man with a mathematical turn of mind, and he has discovered with regard to the urea question in both blood and urine, as well as to the renal functions in general, certain laws that he expresses in the guise of algebraic formulæ. Into this aspect of the subject I shall refrain from following him, frankly confessing my total incompetence in matters algebraic, in spite of the advantages of a university education! Suffice it to say that the accuracy of Ambard's work, and of the conclusions he has drawn therefrom, is demonstrated by its results, and that to-day we have, in what is known as his "uremic constant," an index to the functional value of the kidneys that is completely uninfluenced by the patient's regimen.

By deducing certain laws as to renal functions, and expressing definite figures in the form of letters, and juggling therewith after the fashion peculiar to algebraists, he has established the following equation, which when worked out gives his "uremic constant" K, a numerical index of renal functional value:

$$\frac{U}{\sqrt{D \times \sqrt[70]{P}\sqrt{C_{25}}}} = K.$$

In this equation the numerator, U, is the urea-percentage in the blood; in the denominator, D, is the amount of urea secreted in the urine by the kidneys during the time of the experiment, but referred to a period of twenty-four hours; P is the patient's weight referred to an average of 70 kilos, and C the degree of concentration of the urea in the urine referred for convenience of calculation to a typical concentration of 25 per cent. All this has to be taken on faith, unless the reader wishes to resort for particulars directly to Ambard's papers on the question presented to the Société de Biologie in the latter part of 1910. Here, however, as we are dealing solely with the practical, clinical side of the subject, it will be enough to indicate the manner in which the test is to be made by the practitioner. Unfortunately, the estimation of the urea-percentage of blood serum is far too delicate a matter for the physician; he has here to be assisted by a skilled chemist, who may as well calculate the urea in the urine at the same time.

What the medical man has to do is as follows: Irrespective of diet and time of day, though it is a good plan to administer a pint of water or milk half an hour before the test, simply to get a freer flow of urine, the patient is desired to empty the bladder completely, and the exact time of the end of this emission, in minutes and seconds, is noted on paper. Shortly later, in ten to twenty minutes, the physician extracts the amount of blood necessary for estimation of urea-percentage; 20 c.c. are enough, though 40 are better, and they can be obtained either by wet cupping, vein puncture with a suitable needle, or by venesection. At the end of sixty to ninety minutes, the exact time being not very material, so long as it is noted with equal precision, the patient again empties his bladder, the urine is received in a clean vessel, and urine, blood, time notes and the patient's weight are sent to the laboratory, where the results of the analysis are inserted into Ambard's formula and worked out, giving the uremic constant K, which in the normal state oscillates about the figure 0.070.

It is out of the question, within the limits of an article such as this, to give all the details of so complicated a subject as the establishing of Ambard's equation. The physician's side of the matter is not very difficult; the ascertaining of the result is a laboratory affair requiring great skill and delicacy, and any chemist wishing to carry it out will have to refer to the special papers on the subject to acquire the *modus operandi*. But the clinical value of Ambard's "uremic constant"—uremic referring to urea-percentage, and not to renal insufficiency—is unquestioned, Widal going so far as to say that no physician is justified to-day in having a case of nephritis under his care who does not from time to time look into the urea-percentage of the blood. The figure 0.070 increases the moment the kidneys cease to filter in a normal manner, and long before any special, general symptoms indicate the beginning of the condition of urea-retention that will lead the patient in a varying length of time to the most serious accidents of renal insufficiency. It is precisely on account of its great delicacy and accuracy that this "constant" is so valuable, and its importance lies in its application more to light cases, and to patients with whom real trouble is not yet suspected, than to more advanced and serious cases. When a patient has had chronic nephritis for years, and has reached a point where in spite of care and diet the hematic urea-percentage remains at or over one gram, everyone knows that his condition is grave and the outlook very bad, without having recourse to Ambard's more complicated method, experience having shown that in well-established cases of a certain duration and severity the prognosis follows the blood index alone, for all practical purposes, without further research. But take one of the simplest cases of nephritis, one of the purely albuminous type, in which for years the only symptom observed is a moderate amount of albumin in the urine, the kidneys carrying out their filtering function perfectly in other respects, the patient's general condition being above criticism, and the blood urea index remaining within normal limits. With such a patient as this Ambard's method and formula is the only means whereby we may obtain an early warning as to the approach of the period of trouble, when the kidney disturbance leaves the stage of simple, chronic alteration of one of the primordial renal functions, that of opposing the urinary transudation of the different varieties of albumin in the hematic plasma, and enters the terminal stage of renal retention that will eventually be followed by insufficiency and death, provided the patient does not succumb to some intercurrent disorder in the meanwhile.

The question is one of the greatest interest and practical, clinical importance, and physicians who are at home in French will be well advised in making themselves familiar with it by reading some of the recent work on the subject, of which a summary indication is given in the appended bibliographic list.

# ROENTGENOSCOPIC EXAMINATIONS VERSUS CLINICAL METHODS IN THE DIAGNOSIS OF GASTRIC DISEASE.*

By JOHN DUDLEY DUNHAM, M.D.,
COLUMBUS, OHIO.

The observations to be set forth in this communication are based upon a study of ninety-four patients who consulted me during the past few months. Each patient who complained of gastric or intestinal symptoms was given an Ewald test breakfast, the contents of the stomach removed one hour later and examined. Following this a Riegel test dinner was given, and six hours later lavage was performed to determine the quantity of chyme present at this interval.

Upon the same or the next day the patient was given from fifty to two hundred grams of bismuth subcarbonate or barium sulphate suspended in five hundred c.c. of sweet milk or bread and milk. Fifty received the bismuth mixture and forty-seven the barium.

The roentgenological examination was made by means of the fluoroscopic screen, while the patient occupied a standing position. The outline of the gastric shadow was traced upon the screen at intervals until the stomach became empty. These tracings were transferred to thin sheets of paper and preserved as records.

Before undertaking this work it was my custom to refer patients to a roentgenologist for the examination of the gullet, stomach and intestines. Their conclusions were invariably reached by means of a series of plates. The reports were so at variance with my clinical findings, and indeed with the subsequent diagnosis at operation, that I determined to study the subject from the standpoint of the clinician and alongside the older clinical methods. Patients with even slight digestive disturbances were subjected to the examination. In many instances the indigestion was quite evidently the result of disease in remote organs such as the lungs, the kidneys or in the nervous system.

The examinations made with bismuth subcarbonate were found much more satisfactory than those done with barium on account of the comparative slowness with which the former contrast substance leaves the stomach. We may take the conclusions of Groedel as well established that barium leaves the stomach two hours sooner than the bismuth.

Every contrast substance as yet discovered undoubtedly produces a vastly different reaction upon the gastric musculature than the customary articles of food. Barium excites peristalsis too markedly for a satisfactory study of hypertonicity and hypotonicity.

Stiller's contention that a stomach in normal digestion cannot be shown by the roentgenologic method is well taken. No doubt the normal stomach is not tube but sack shaped during the digestive process. Until a new contrast material is found this criticism must remain a serious drawback in the Roentgen method of investigation.

The diagnoses are as follows: Group I, chronic gastric ulcer with stenosis (operated), 10; Group II, chronic gastric ulcer (not operated), 21; Group III, duodenal ulcer (operated), 4; Group IV, Duodenal ulcer (not operated), 2; Group V, neurasthenia, 21; Group VI, pyloroptosis, 11; Group VII, pulmonary tuberculosis, 5; Group VIII, atony, 6; Group IX, chronic gastritis, 4; Group X, cardiovascular disease, 3; Group XI, cholelithasis, 2; Group XII, cancer of the pylorus, 2; Group XIII, preataxic tabes, 1; Group XIV, diabetes, 1; Group XV, appendicitis, 1. Total, 94.

The most interesting case in Group I is that of a woman of fifty-one years who suffered from pain three to four hours after meals for three years. Acid foods increased the severity of the pain. She had lost fifteen pounds in six months during which time she had passed tarry stools upon two occasions. After an Ewald test meal the hydrochloric acidity was sixty and the total acidity eighty-five. Six hours after a test dinner 150 c.c. of chyme was recovered. Clinically this seemed a case of chronic gastric ulcer with a relative stenosis.

The fluoroscopic examination showed the usual J-shaped stomach with the lowest point two fingers breadths below the umbilicus. The peristaltic waves were not increased above the normal. Three and one-half hours were required for the 75 grams of barium to leave the stomach. Four hours after ingestion of the Roentgen meal there was observed in the left hypochondriac region a shadow which presented the appearance of a dumbbell. The end could be seen to alternately increase and decrease in size with a long, narrow constriction between. In this case the obstruction was apparently in the small intestine rather than at the pylorus.

A second patient with gastric ulcer had been subjected to medical treatment upon three occasions over a period of six years without relief. This patient gave a history of repeated haematemesis and typical pains three to four hours after meals.

The hydrochloric acidity ranged from 48 to 68 and the total acidity from 60 to 100. Occult blood was frequently found in the stomach contents and the stool. Six hours after a test dinner lavage revealed no chyme. The screen examination showed a very acute angle formed in the prepyloric region by the lesser curvature. No hyperperistalsis was seen. The barium meal had disappeared within two hours. Operation revealed a slight ulcer scar on the anterior surface of the pylorus but without stenosis.

Three patients showed persistent indentations in the greater curvature in the pyloric or prepyloric region after the Roentgen meals. At operation extensive stenosis was found in each case resulting from ulcer scars. The remaining five cases of operated gastric ulcer were found with marked ste-

*Read at the meeting of the American Gastroenterological Association at Washington, D. C., May 5 and 6, 1913.

nosis at the pylorus. Each case presented a normal appearance after the Roentgen meal, and in each case the bismuth or barium had entirely disappeared within three hours after ingestion.

Clinically all presented a typical history of gastric ulcer with the early stages of stenosis. Hyperchlorhydria was found, and a varying amount of food was present seven hours after the test dinner.

We find in Group I eight patients who suffered from pyloric obstruction of such a degree as to justify the performance of a gastroenterostomy. The roentgenoscopic examination gave no evidence of stasis or chyme. In this class of cases the performance of lavage is a reliable indication, while the *x*-ray examination is misleading. Group II—In this series one case showed a large amount of barium in the stomach five hours after ingestion, but was empty in seven hours. Lavage showed the presence of food twenty-four hours after a test dinner.

Twelve cases of gastric ulcer showed on the screen no antiperistalsis or hypertonic waves, while in each instance the stomach was empty within three hours. Typical histories with hyperchlorhydria and occult blood were found in each patient. In two lavage was performed seven hours after a test dinner and more than 200 c.c. of chyme recovered. Three were found with a marked acute angle in the lesser curvature and were empty of food and Roentgen meal within the normal time.

A man of seventy-three years presented a typical history of duodenal ulcer over a period of ten years. The test breakfast showed an hydrochloric acidity of 44, and a total acidity of 59, and the presence of occult blood in the stomach contents and stool. The fluoroscopic picture showed a hypertonic peristalsis with a failure of the prepyloric region of the greater curvature to assume its proper contour. Massage over this area during the examination made no change in this defect.

A diagnosis of ulcer probably of a carcinomatous character was made. The patient completely recovered after the rest and milk cure preceded by rectal feeding. The diagnosis in the four remaining cases of gastric ulcer was difficult without the use of the roentgenoscopic observation. In each instance a circular shadow persisted in the pyloric region even after the barium had entered the colon. These patients apparently recovered after the rest and milk cure. The conclusion was that a peptic ulcer existed which had involved the deeper layers of the gastric wall.

Group III.—The diagnosis in three of the six duodenal ulcer cases was aided by the presence of marked hypertonicity of the peristalsis. One patient, a man of fifty years, presented a typical picture of duodenal ulcer with very alarming malaena. The fluoroscopic shadow, however, revealed a markedly contracted stomach. Upon this latter evidence my diagnosis of cancer of the stomach was predicated. The patient succumbed after a violent hemorrhage, and the necropsy revealed a perforating duodenal ulcer.

The crescentic form persisting for five hours after a bismuth meal was found in one instance in which the test dinner had disappeared in six hours. Operation showed a marked stenosis due to adhesions just below the pylorus.

Group V.—Pseudo hour-glass stomach was found in two of the twenty-one patients with neurasthenia. The stomach when observed under the screen was divided at the upper third into two quite distinct pouches. The spasm persisted for two hours in spite of the effect of massage and exercise during the intervals of examination. Subsequent fluoroscopic examinations failed to show this condition. *X*-ray plates even by the stereoscopic method would fail to diagnose these cases.

Group VI.—The diagnosis of pyloroptosis is greatly aided by roentgenoscopy. This method is less likely to produce errors than the inflation of the stomach with $CO_2$, air, or by the employment of the deglutable electric light.

Group VIII.—The greatest disappointment in gastric diagnosis by means of the Roentgen ray is found in cases of motor insufficiency and atony. Bismuth and barium seem to cause weaker peristaltic action than one finds after a normal meal. The fluoroscopic half-moon shaped appearance persists for twelve to twenty-four hours. On the other hand, lavage may show an empty stomach eight to ten hours after a Riegel meal. The milder degrees of motor insufficiency caused by a weakened musculature cannot be determined by the roentgen method.

Group XII.—The diagnosis of the cases of pyloric cancer was made before the development of tumor. Both patients had suffered from loss of weight and strength, with a sudden onset of digestive disturbance. One had hematemesis and melena and the other showed no such signs. In both a persistent irregular outline was found near the pylorus. In one case the diagnosis was confirmed by autopsy; in the other by operation. The remainder of the cases in other groups presented normal fluoroscopic appearances.

*Conclusions.*—(1) Because of the relative slowness with which bismuth leaves the stomach it must be considered the most satisfactory contrast substance as yet employed.

(2) In cases of clinical gastric ulcer the failure of the pyloric region of the stomach to assume its symmetrical contour with the Roentgen meal is strongly presumptive of stenosis.

(3) The emptying time of the Roentgen meal is of no value to determine the early stages of pyloric stenosis. Lavage at varying periods after meals remains the only test of this condition.

(4) Hour-glass stomach is capable of diagnosis by the fluoroscopic method while other methods are entirely unreliable. Errors are easily made if careful and prolonged study is not undertaken.

(5) Fluoroscopy offers great aid in the differential diagnosis of motor insufficiency caused by atony and that produced by an advanced stenosis at the pylorus. Clinically one finds similar symptoms with a reduced hydrochloric acidity in each instance.

(6) The degree of motor insufficiency and atony cannot be determined by the present Roentgen method.

(7) Roentgenoscopy of the stomach is no more an exact mathematical method than percussion. At best deductions must be made from shadows.

(9) The best results in gastric diagnosis will be attained when the clinician himself employs the fluoroscope examination as one of his own clinical methods.

# THE IMPORTANCE OF ADOPTING A MORE ACCURATE METHOD OF EXAMINATION FOR COLOR-BLINDNESS.

By JAMES A. NYDEGGER, M.D.,

BALTIMORE, MD.

U. S. PUBLIC HEALTH SERVICE.

In presenting a paper of this character before a body of professional men, it may seem unnecessary to enter into any discussion of the fundamental principles underlying color perception and color-blindness, but perhaps it might be well to refresh our memories somewhat on the physics of light and the process of perception of colors in the eye, so that we may better understand the subject before us this evening.

If a ray of white light is passed through a prism, the light, as it emerges from the prism is found to be broken up into various colors, which are known as the seven spectral colors. These colors are seen to be arranged from above, downward, according to their strength and greatest wave lengths, beginning with red at the top, which is the strongest, and has the greatest wave length, and running downward through orange, yellow, green and indigo, to violet at the bottom, which is the weakest and has the shortest wave length.

The human eye is supplied with perceptive nerve fibers through the optic nerve, which entering the eyeball at the posterior surface, break up into innumerable nerve filaments, which terminate in the retina, the innermost coat of the eye.

A proper division and a consequent correct understanding of color-blindness was not made until the latter half of the last century. Then it was that Helmholtz brought forward the long forgotten work of Young, and applied his theory of color perception to the result of modern investigators, with the final development of what is now called the Young-Helmholtz theory of color sense.

In order to demonstrate clearly they assume subjectively a reduction of colors to three base colors, which is but reducing or carrying back the sensation of colors to their base or final sensations. On this assumption, there are in the eye, three kinds of nerve fibers, those for red, green, and violet. Stimulation of the first produces the sensation of red, the second that of green, and of the third, the sensation of violet.

Objective, homogeneous or white light excites these three kinds of fibers in varying degrees according to their wave length. The red perceptive fibers will be strongest stimulated by light of the greatest wave length, the green perceptive by light of medium wave length, and the violet perceptive by light of the shortest wave length. Here must be accepted also the theory, that each spectral color (the colors resulting from breaking up white light) excites all three kinds of fibers—but one less, the others more strongly. Thus, if we suppose the spectral colors are arranged in a horizontal row, instead of vertical, as we are accustomed to see them, beginning with the red at the left and running to violet at the right, then three curved lines of varying lengths can be made to represent the intensity of stimulation of these three kinds of fibres; (1) the red perception, (2) the green perception, and (3) the violet perception or elements. Thus, in a normal eye, simple red strongly stimulates the red perceptive fibers, less the other two; sensation red. Simple yellow stimulates moderately the red and green perceptive, feebly the violet; sensation yellow. Simple green stimulates strongly the green fibers or perception, much less the other two; sensation green; and thus through all the remaining colors of the spectrum, to violet, which stimulates strongly the violet perceptive, feebly the other fibers; sensation violet. Equally strong stimulation of all the fibers gives the sensation of white or whitish colors.

It is not absolutely necessary, as has been assumed above, to suppose the existence of separate nerve fibers in the eye for these separate sensations. The theory would be of the same value if we supposed that in each individual fiber three different and independent actions took place. As the sense of

touch and the sense of sight in the eye, have evidently separate nerve fibers, so may the same be claimed for the sensation of the several base colors. The choice of the three colors named is somewhat arbitrary. Any three colors could have been taken whose combination produced white light.

With a diagram showing the curved lines representing the strength of the light waves above referred to, one is enabled to show what proportion each one of the fundamental perceptions enters into the colors of the spectrum, which is done by measuring the vertical distances from their place on the horizontal line to the corresponding points of each of the three curves. It is then seen that there is no color of the spectrum into which but one primitive color enters exclusively. The two others also furnish their contingent. No one (color) is therefore perfectly saturated (that is, coming from one color source alone). They are more or less spread with white and green in the lowest sensibly "saturated" or more-whitish. The curves also show us that yellow and blue are at the same time whitish colors, and the most intensely luminous in the whole spectrum. When we again add that a color "saturated" in almost the same degree as the other spectral colors, proceeds from a homogeneous combination of red and violet; that is to say, purple, and its whitish shade, pink, about all has been said in a theoretical way that may be said in relation to the chromatic or color sense.

To explain the abnormal sense of color or color-blindness, by the theory of the normal, we can in advance, conceive various possibilities. Let us suppose that one of the three fundamental perceptions is wanting or that one of the primitive colors is absent in the eye. It is clear that the whole color system will be upset.

It is evident therefore that this system must be completely different according to the absence of one or the other of the three primitive colors. It is virtually just in this way that it has been attempted to explain cases of strongly marked defect in the color senses or genuine types of blindness to color, found in real life. The term color-blindness has been justified by this, as it indicates a blindness to one of the primary colors. In this way, therefore, we distinguish according to the kind of element wanting, three classes of blindness, viz.: red-blindness, green-blindness and violet-blindness.

The color-blind have not the receptive or percipient organ for that color, and according to this theory, blindness to red is caused by the absence or paralysis of the organs perceiving red, and red blindness has then but two fundamental colors, which, adhering to the theory, as announced, are green and violet. Spectral red which feebly excites the perception organs of green, and scarcely at all, those of violet, must consequently appear to the red-blind, a "saturated" green, of a feeble intensity more saturated than normal green, into which a sensible portion of the other primitive colors enter. Feebly luminous red which affects the perceptive organs of red, in the normal eye sufficiently, does not, on the other hand, sufficiently affect the perceptive organs of green in the red-blind, and it therefore seems to them black. Spectral yellow seems to them a green saturated and intensely luminous and as it constitutes the precisely saturated and very intense shade of that color, it can be understood how the red-blind select the name of that color, and call all those tints that are, properly speaking, green, yellow. Green shows as compared with the preceding colors, as a more intense but whitish shade of the same color, as yellow and red. In fact, it is clear that a red and a green light excite one and the same elements in the red-blind. A red or green or an object red and green to the normal sense must seem fundamentally to the red-blind, to be the same color, and, if in an especial case, he knows how to discriminate, his judgment is simply guided by an intensity of the light. If then, a red-blind individual finds that a red and a green tint are exactly alike, it is necessary that the green be to the normal eye much less intense than the red.

Green-blindness derives its origin according to the theory from the absence or paralysis of the perceptive elements of green. The green-blind has, therefore, but two fundamental colors, adhering to our first theory—that is, red and violet. The spectral red which strongly excites the perceptive organs of red in the eye, and but very faintly those of violet, must therefore appear to the green-blind, as an extremely "saturated" red, but of a light, somewhat less intense than the normal red, which is comparatively more yellowish, as green forms a part of it. The spectral orange is again a very saturated red. But much more luminous. Yellow is also a more intensely red than spectral red, but on the other hand, more whitish, because a sensible portion of the other primitive colors enter into it. Green, with its shades, including yellow and blue, ought to be, correctly speaking, a saturated purple and with a mean intensity of light, but it is the gray of the green-blind, for it is composed of almost equal parts of the two primitive colors. Purple green and gray pass with the green-blind, for one and the same color.

In green-blind the same organ is also found affected by spectral red and green light. Red and green are then perceived by the green-blind in the same way; or, in other words, are to him in fact, exactly the same color. In cases where he succeeds in distinguishing them, one from the other, it is by the aid of the intensity of light. It is the opposite of what occurs in the case of the red-blind. A green tint, which to the green-blind must appear exactly like a red one, to a normal sense of color must be sensibly more luminous than red.

Violet-blindness, according to the theory, is due to the absence or paralysis of the elements perceiving violet. The two primitive colors of violet-blindness, according to the theory, are red and green. The red is a purer red color than normal red, but still less saturated. The green is a stongly luminous but whitish green, tending toward blue. The violet-blind do not confuse the colors of red and green, and this type of color-blindness is very rare.

Now, having considered the process of perception of color in a normal eye and in the color-blind, let us look at color-blindness from a practical point of view, and consider the dangers, to life and property, resulting from color-blind persons being employed in positions where it is necessary to properly distinguish the various color signals used.

To Holmgren, who originated and published in 1887 his method of examination for color-blindness, do we owe, above all others, the present and future control of color blindness, on land and sea, and by which life and property are safer and the risks of traveling less.

It has been determined that one male person in twenty is color-blind in a greater or less degree, and there are all grades of color blindness, from

defective to complete. The proportion of color-blindness in women has been found to be about one in every one hundred. This is explained by the law of non-heredity on the mother's side.

Of this defect, those so afflicted may, even themselves, be wholly unconscious. The majority of cases of color-blindness are congenital, and are largely of a hereditary nature and, as such, have been known to run through several generations of a family; and this form of the defect is incurable. Color-blindness may also be temporarily or permanently caused by disease or injury.

Color-blindness is red, green, or violet, and exists in varying degrees. It may be complete or partial and the latter is designated as color-defective or incomplete color-blindness. We may suppose, in comparison to the normal color sense, that feeble or defective or incomplete color-blindness is due either to a weaker response to excitation on the part of the color-perceptive organs of the retina, or to the presence in the retina of a relatively small number of these organs. Exercising the eyes with colors, and the ears with their names, helps the color-blind to supplement their eyes, but does not change their color perception.

Experiment and experience show that we are forced to use red and green signal lights to designate a vessel's direction of motion and movement, and at least red and green on railways to denote danger and safety.

It is a unique coincidence and seems particularly unfortunate that the most common form of color blindness, red- and green-blindness, should be the identical colors that have been selected by all nations to be carried on the two sides of a vessel, from sunset to sunrise, as signal lights, and also used on all railroads by day and night for similar purposes. These colors were selected (doubtless) because of their brightness and the distinctness with which they are seen, a long time before anything was known of color-blindness, or it was even thought of.

If color-blindness is considered a grave danger on the railroad, how much more is it on the sea. Colors are very important to mariners. The flags for signals, the side lights of vessels for danger, and even the lighthouses, the beacons and buoys present various colors necessary to be distinguished.

A very grave defect with the present Holmgren method now chiefly in use in examinations for color-blindness, may be shown as follows: The majority of even color-blind persons are well able to distinguish bright red from bright green when they are near the eye, and well illuminated, but this power diminishes with great rapidity when they are removed to a distance from the eye, so that separation of a few feet or a few yards, according to the severity of the case, abolishes all sense of distinction between red and green. As the colored day signals used on railroads, especially the flags, which alone are available in some of the most pressing emergencies, soon tarnish and darken; the effect of time is to change light reds and greens into much darker shades, and thereby to continually diminish the distance (small at the best) at which the two danger signals can be distinguished from each other by color-blind observers.

It is just such cases as those above referred to that may succeed in passing a test examination undetected, by the prevailing method, unless the test is supplemented by some other more accurate means of detecting the existing color-blindness. For we know the Holmgren method consists of selecting colored skeins placed at no appreciable distance from the eyes. The practice of permitting employees, other than professional men, as is the custom of many railroads, to conduct these examinations, tabulating the result on cards, to be examined later by the surgeon, is, to my mind, a dangerous procedure and one which should be prohibited by law. A skilled professional man, thoroughly experienced and posted in this work, alone should conduct these examinations. It is not the work that a novice or beginner in the practice of medicine should be permitted to perform, let alone the trusting of such important duties to a non-professional man.

It may well be stated that the Holmgren color test as employed in examinations for color blindness, is in many instances unsatisfactory, and with our present knowledge inadequate, and should, when used, be supplemented by an additional examination, and is a matter which warrants earnest consideration. It has been shown that when used alone, the Holmgren method fails to detect all cases of color blindness.

In view of the revelations made while conducting these color tests it is highly important, as a check on the Holmgren skein test, that a supplemental lantern test be adopted with which, by the use of various colors and apertures of different sizes, the defect of color blindness can be easily detected under conditions such as those which naturally prevail at sea or on railways.

In the case of masters, mates, and pilots of vessels, who periodically are required to undergo the test for color-blindness, there is a natural objection to the Holmgren method, and should the applicant fail to pass the test satisfactorily, the claim is promptly set up that he can readily distinguish the various signal lights used on vessels. In numerous instances this claim has proved to be correct when resort was made to that mode of procedure. The above will apply equally as well to employees of railroads, since they, too, are also required in the same way to stand the test for color-blindness. In many instances, too, the Holmgren skein test has proved confusing, and it has been next to impossible to make the individual thoroughly comprehend what is expected of him.

It is a well known fact that while many color-blind people are able to match colors with accuracy, they are unable to name the colors correctly, particularly if they are examined under conditions that naturally prevail, such as the presence of mist or imperfect illumination, and the varying effects of distance and size of the colored subject.

As one of the reasons for the necessity of a double test, by means of a special lantern, Dr. W. F. Edridge-Green of England, who is probably the greatest living authority on color-blindness, cites the case of an individual who, when examined with the largest apertures of the special lantern invented by him, mistook red for green and vice-versa, who nevertheless was able to pick out and match all of the five test colors of the Holmgren method, in which the color names are not used.

Having recognized the defects of the Holmgren test, the British Admiralty has adopted the Edridge-Green lantern as the best means of detecting all cases of color-blindness. It is properly claimed that the Holmgren method, in addition to rejecting many normal sighted persons, allows a large per cent. of those who are dangerously color-blind to pass.

As the Holmgren method is now universally in

use, it should not be dispensed with, but it should be supplemented by the lantern test in all cases.

It is a matter of such vital importance, where the lives of many thousands of persons are daily dependent on the perfect color sense of those to whose care they are entrusted, on railways and vessels, and also property of great value, that no precautions that are possible within our knowledge should be neglected or overlooked to afford every safeguard and protection.

As a step toward the proper solution of this question, it might be proper, at this time, to suggest the selection of a committee, to be named by the Section on Ophthalmology of the American Medical Association to make a comparison of the Holmgren test, with the special lantern test, as is now used in England, and make recommendations as to the relative merit of these methods, with reference to adopting a new standard test for color-blindness.

Observation and experience extending over more than twenty years in the use of the Holmgren method, has led to the conclusion and the belief that the Holmgren test as now conducted should be supplemented by the lantern test, which is more accurate and better adapted for the detection of color blindness.

## GLYCOSURIA AND THE BULGARIAN BACILLUS.

By S. H. BLODGETT, M.D.,

BOSTON, MASS.

Some time ago on account of articles appearing in medical journals in relation to the action of the Bulgarian bacillus in cases of glycosuria I determined experimentally to place a number of cases in my clinic under this treatment, and to this end wrote for directions to one of the physicians who had had a great deal of success and was mainly instrumental in bringing the treatment to public notice. He very kindly offered to direct the treatment if I would send him the history, symptoms, diet, etc., of the cases. To make the experiment more conclusive, because I felt that there might be a question in relation to the activity of the particular brand of the bacillus used, I changed the brand of the bacillus in two of the cases without making any change at all in the diet.

As it seems only right that we should record for the benefit of our confrères our failure as well as our successes, I am reporting these cases. I would state incidentally that a couple of years ago I classified the various forms of glycosuria, describing the symptoms, the diagnosis, and prognosis of each form, and referring to that division I would say that two of the cases reported are of the form classified as Type B; four are of Type C (one of these having been discovered very early), and one is of Type D. In this series of cases I have included each of the types of glycosuria except that which has its initial trouble in the fourth ventricle, and while I have had two of these cases at my clinic since I have begun this experiment, I have felt that it would not be of any use to try the bacillus in these cases, as they responded very readily to treatment directed to the initial trouble in the brain and required no treatment in relation to the sugar in the urine. I would also state that in each of these cases I have a full history and daily diet list and the almost daily analysis of the urine, and my notes also show the daily amount of labor each patient has performed. As it would be beyond the limits of this article to record all this, I shall record only the essential points, but I should be very glad, if it is of interest to any one, to give him the daily lists.

Case I.—Glycosuria. Type D. Young man eighteen years of age, rather tall and thin, gives following history: Father and mother perfectly well; up to three years ago had been well but at that time noticed that he was exceedingly thirsty. He consulted a physician and sugar was found in large amounts in the urine. He weighed at that time 138 pounds, and by careful dieting the physician said that he was able to have the urine free of sugar. The case went along for three years, at times the sugar being entirely absent. He grew tall during that time, continued at school, and increased in weight to 153 pounds. He thinks that his urine has not been free from sugar, as far as he understood his physician's report (his physician has recently died) for the past year and a half. He now weighs approximately 148 pounds. He has had diarrhea several times since he has been on the diet, but otherwise he has been quite well except for an occasional cold. He was put on a moderately strict diet, of which the following is a fair sample: Breakfast, one-half grape fruit or orange, eggs (with an occasional small amount of bacon), rolls made from peanut flour, 2 ounces of thoroughly cooked oatmeal. He was allowed what fresh milk he wished to drink at any time. Lunch, thin soup, meat, onions, spinach, orange jelly, or some other saccharin dessert. Dinner, thin soup, small amount of meat, some green food, 1 ounce of white bread, 1 ounce of rice, apple sauce sweetened with saccharin, 1 ounce of nuts. While this was a typical diet, still his food was varied from day to day by the substitution of other articles not containing, however, any more carbohydrate, so that throughout the time of the treatment he ate a large amount of food with great relish and digested it very well. During the

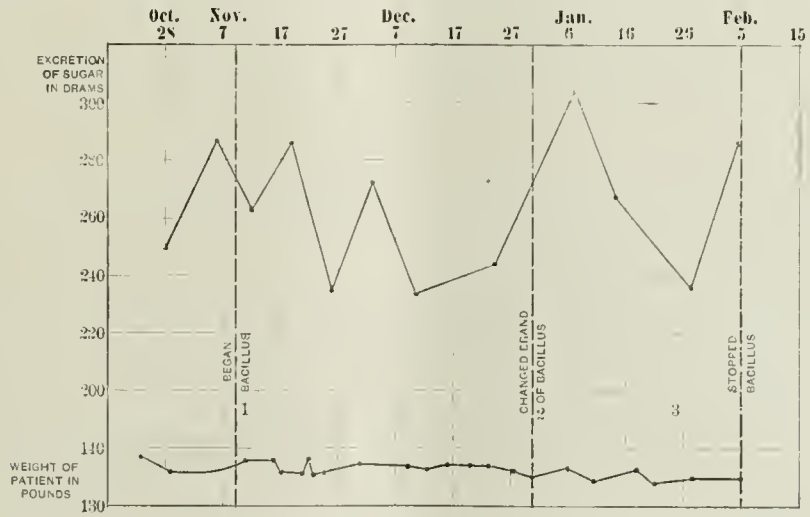

Chart No. I.

time of the experiment he continued at school daily, but took very little exercise besides his short walk to school and back again, although he slept in a room to which the outdoor air had free access during the night. Twice during the treatment he took a severe cold, which, however, only lasted for a few days. From October 28 to November 12 he was on this diet. On November 12 he was given a dose three or four times a day of the Bulgarian bacillus.

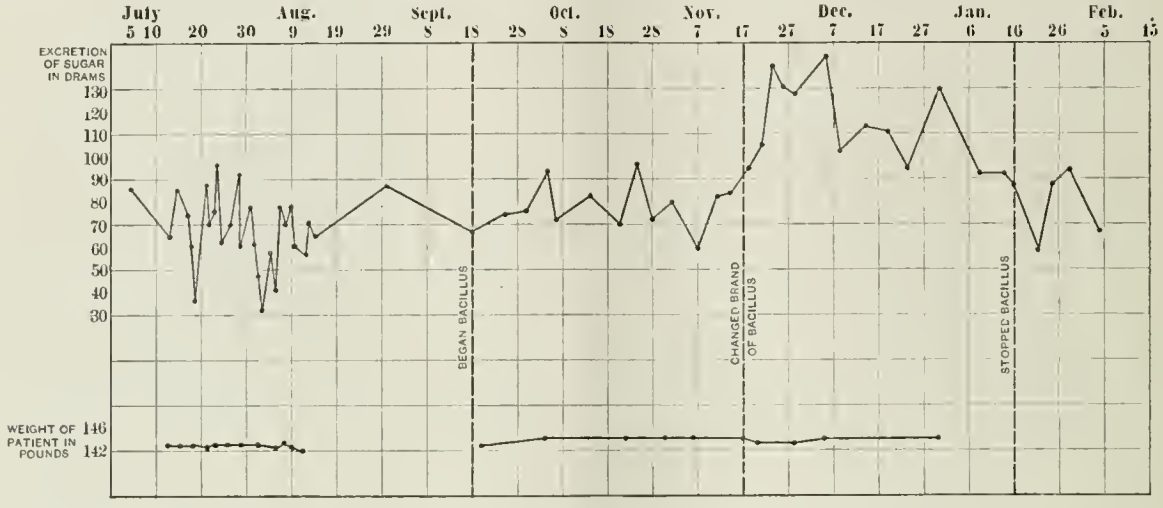

Chart No. II.

It was administered as follows: 7 c.c. of the bacillus (which had been kept cold) was mixed each morning with 3 ounces of water. One-third of this was taken one-half hour before breakfast, following it immediately with 3 ounces of milk. Another ounce of the mixture was taken at luncheon time followed by milk, and the remaining amount of the mixture was taken one-half hour before supper, following it with 3 ounces of milk. Several times during the treatment a fourth dose was given one-half hour before bedtime. The bowels were moved freely twice each week, using castor oil, and the reaction of the feces was taken twice each week. This reaction was never alkaline; it was several times neutral but usually strongly acid. Without any change in his diet or way of living this was continued until January 1, at which time he was given another brand of the Bulgarian bacillus. This bacillus was given as follows: The contents of one tube of the Lactobillene Liquide was added directly to half a glass of warmed milk, which was drunk one-half hour before each meal, and a fourth dose before retiring at night. This was continued up to February 4 at which time the medicine was stopped and he was continued on the diet without any medicine at all. His weight, as will be seen from the chart, while not having changed much, showed a slight tendency to decrease. As far as the amount of sugar in the urine was concerned there was apparently no change whatever while he was taking either form of the bacillus. The variations in the excretion of sugar in his case (and in most cases of this type) were considerable and were only what would naturally be expected, as can be seen by comparing Case VI, which I have used as a control case.

Case II.—Glycosuria. Type B. Man about forty-six years old. Family history good. Four years ago he was troubled with night sweats. At that time his physician examined his urine and found that it contained sugar. He was very stout at that time but gradually decreased in weight from 175 pounds to 134 pounds. His weight then began to increase and went up to 150 pounds. At the beginning of this treatment it was 145 pounds. He had never had a history of extreme thirst and had never passed exceedingly large amounts of urine. An analysis made a year before coming into my hands showed 87 grams of sugar. As far as he understood his physician, his urine has never been free from sugar since it was first discovered four years ago. When he came into my hands he was following a printed diet list, with the addition of so-called "gluten flour" bread. The variations during the first month were very marked and were due entirely to various changes in the diet. For instance, on July 15 he was given the following diet: Breakfast, orange, ham and eggs, glass of milk. Dinner, thin soup, fish or meat, tomatoes, milk, iced tea. Supper, thin soup, meat, spinach, raspberries and cream, iced tea, milk, and also what water he cared to drink. This diet was continued four days, accompanied, as will be seen by referring to the chart, by a steady decrease in the amount of sugar. To this diet was then added 2 ounces of cereal for breakfast, 1 ounce of bread for dinner, 6 ounces of green peas and ½ ounce of bread for supper, and this change was followed by a corresponding increase in the amount of sugar. During the next few weeks I was giving him various amounts of different kinds of carbohydrate and watching the excretion of sugar following the ingestion of the different forms of carbohydrate. By August 15 I succeeded in arranging a fairly satisfactory diet on which he seemed to be able to attend to his work, feel

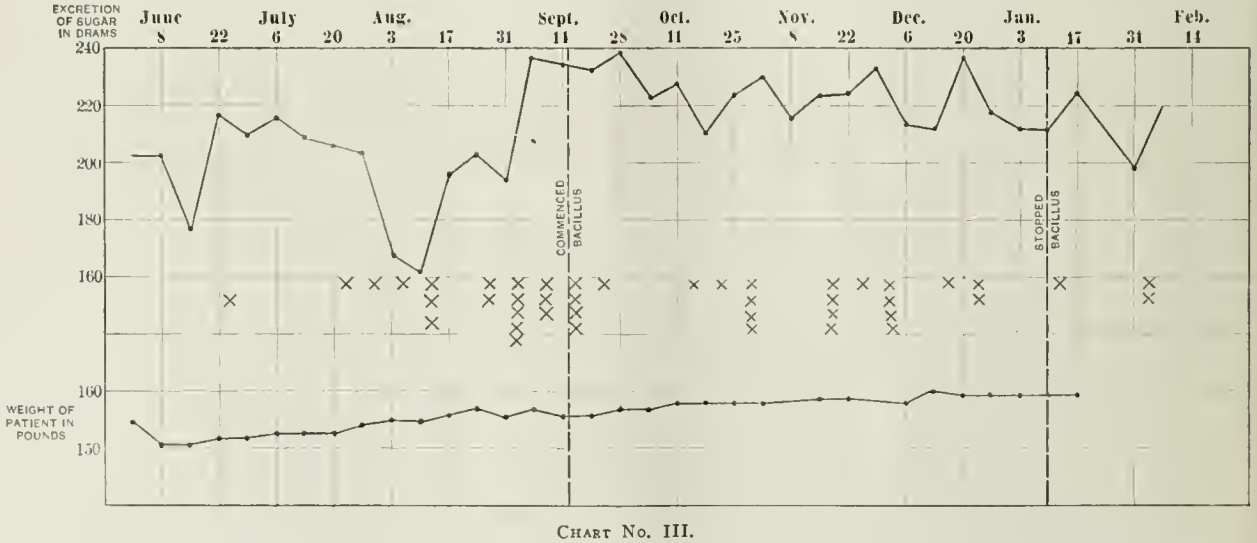

Chart No. III.

well, and not decrease in weight. It contained as the carbohydrates 2 ounces of oatmeal in the morning, 2 ounces of white bread at some time during the day (usually part of it at noon), and on September 7 I added 1 ounce of rice at night. This was continued and on September 18, without any change in the diet, he was given one tube of Bulgarian bacilli mixed in milk one-half hour before each meal. His bowels were moved freely on two regular days each week sometimes by the aid of castor oil and sometimes by the aid of Hunyadi water. This was continued up to November 17, a period of nine weeks, without any apparent change. At that time without making any change in the food he was placed on another brand of the Bulgarian bacillus, given in the following manner: 7 c.c. were mixed with 3 ounces of water, 1 ounce of this mixture was taken one-half hour before each meal and immediately following it one-half glass of warmed milk was taken. The amount of sugar in the urine steadily increased. Early in December the patient complained of not feeling as well as he had previously felt and that he found it harder to attend to his duties. He was continued on this treatment until January 16, a second period of nine weeks, at which time, as will be seen from the chart, there was no appreciable change in the amount of sugar excreted. On that day he was placed on a starch-free diet with the result that the sugar was decidedly decreased. He was then given small amounts of carbohydrate, somewhat less, however, than he had been taking before January 16. The rice was entirely eliminated and only one-half of the oatmeal was allowed. His weight, while it had only varied very slightly during the experiment, had shown a slight tendency to increase.

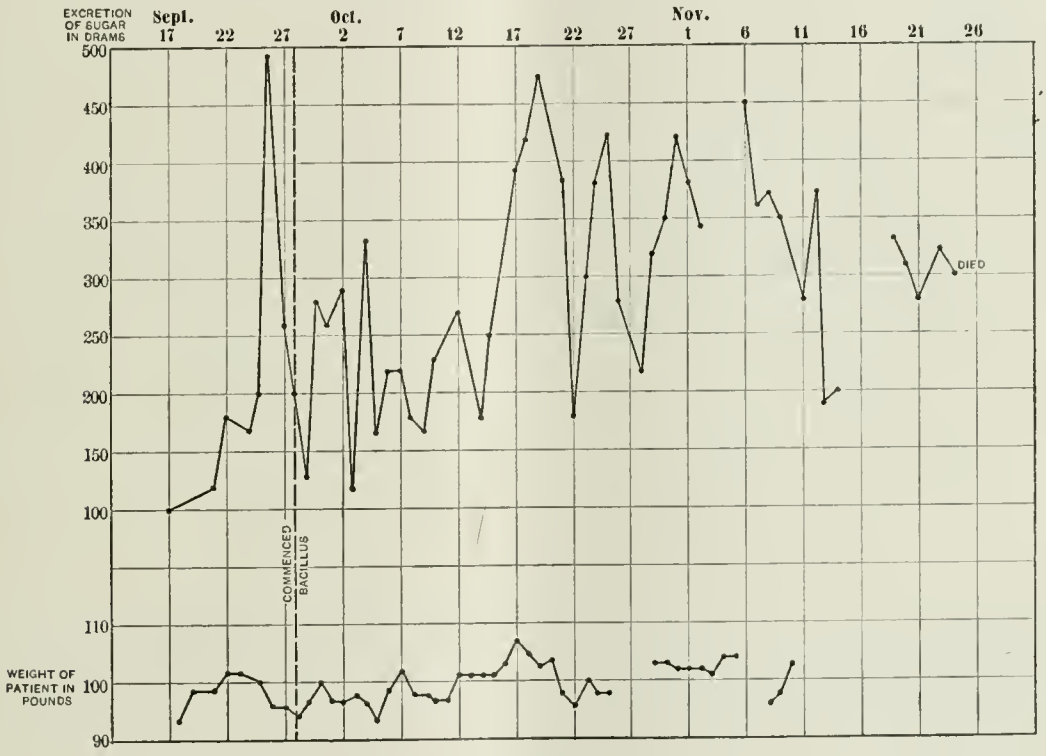

Chart No. IV.

Case III.—Glycosuria. Type D. This was a case occurring in a young man about twenty-one years of age. He was seen very early, in fact, soon after the onset. When commencing treatment it was very easy to make the urine sugar-free and I found that the patient was able to take as much carbohydrate as was contained in 1 ounce of white bread three times a day, without showing any sugar in the urine. He, however, began eating candy and cake and we found the sugar present again. After that, as always occurs in this type of case, it was more difficult to keep the urine sugar-free than it had been previously. As during the experiment the sugar was present only at certain times and it was impossible on account of the small amount to estimate its quantity, I have drawn diagrammatically on the chart his specific gravity and also his weight. In this case I have only charted the data beginning in June as this will cover a considerable period before he began taking the Bulgarian bacillus. This has been shown each week and the crosses indicate the number of days on which a trace of sugar was found during that week. The lower line indicates his weight. It must be noted that this had increased during the previous six months (while he had been under my care) from 140 pounds to 155 pounds. During the first two weeks, as shown on the chart, his weight dropped to 150 pounds due to a severe diarrhea following the eating of some decayed fruit. A typical diet, such as he was taking from June until the beginning of the treatment, would be about as follows: Breakfast, orange or grape fruit, eggs with at times a little ham or bacon, weak tea or coffee with cream, two Casoid biscuits and butter. Dinner, thin soup, cooked vegetable (as cabbage, spinach, dandelions, asparagus) and an uncooked vegetable (as lettuce, celery, cucumber), meat, saccharine dessert. Supper, thin soup, meat or fish, cooked vegetable, uncooked vegetable or an orange, cheese or olives, saccharine dessert, milk. On August 31 to his diet list was added 1 ounce of thoroughly cooked oatmeal for breakfast, and 1 ounce of white bread for dinner, 1 ounce of rice at night. As will be seen the specific gravity took a sudden jump and traces of sugar were found present in the urine during five of the next seven days and three times during the second week. Without changing the diet in any way he was then given a preparation of Bulgarian bacilli. The contents of one tube mixed with warm milk was taken one-half hour before each meal and the contents of a fourth tube which had been mixed in milk at noon and kept warm was given to him when he went to bed at night. This was continued without intermission until January 10. I also discontinued the rice and one-half of the amount of white bread which he was taking. The specific gravity of the urine remained about the same during the course of the treatment. There was a marked increase following the addition of the extra carbohydrate (about September 5) and there was an increasing number of times when sugar was present in the urine. The weight which, on account of the intestinal disturbance, had fallen to 150 pounds had gradually increased to 156 pounds when the ferment was commenced and kept on increasing to approximately 159 pounds. The weight did not seem to be influenced at all by the bacillus. This case was on the particular preparation of Bulgarian bacilli for four months continuously.

The next three cases make a very interesting series when compared one with the other. The three cases were each under my care at the same time. They were each of the same form (Type C), and the diet in each case was, as far as possible, the same. The amount of non-carbohydrate food which each patient took varied one from the other according to each patient's appetite, but the amount of carbohydrate food taken was identically the same

each day, both as to amount and variety, except that once or twice one or another of the patients would become tired of the oatmeal or rice, in which case we substituted wheatena, giving exactly the same amount. Two of these cases were treated with the Bulgarian bacillus, while the third case received no medicine at all, being used virtually as a control case.

Case IV.—No history of glycosuria in family. Case of boy aged about sixteen years. Struck with a brick on the head about four years ago. He was unconscious for some little time, was taken to the hospital, and some stitches were taken. The 2-stitch scar shows now on the right side of the occiput. Two months previous to admittance he noticed that he had a good deal of thirst and was passing a large amount of urine. He was dizzy and felt weak. He went to the out-patient department and after two months' treatment was referred to the hospital. He was poorly nourished and undeveloped. He was on a rather strict diet which, as far as possible, I tried to continue. Seven days after he was admitted he had an ulcerated tooth which caused his face to swell and which also caused him a great amount of pain. The urine excreted during the time showed a large increase in the amount of sugar, reaching almost 500 grains in the twenty-four hours. During the late afternoon of that day his abscess broke and the dentist also treated it, with entire relief of the pain and swelling. It was very curious to see how rapidly the sugar disappeared during the next forty-eight hours. On the morning of the twelfth day his output of sugar having returned approximately to normal, there was added to his diet 1 ounce of well-cooked oatmeal in the morning, one slice of white bread for dinner and 1 ounce of cooked rice for supper, and as a medicine he was given one tube of a preparation of Bulgarian bacilli dissolved in warm milk one-half hour before each meal and another at bedtime. The output of sugar continued with considerable variations from day to day as it always does in these cases, showing a somewhat upward tendency due to the addition, undoubtedly, of the extra carbohydrate in the form of the oatmeal, white bread, and rice. On October 15 he showed symptoms similar to the grippe, having headache, pain in his muscles and joints, and considerable running from the nose. This continued for several days and probably entirely accounted for the rise in sugar output (his diet was not changed at all except that he did not eat as much of the articles allowed as previously.) October 19 his temperature was normal, and on the 21st he seemed to have completely recovered and was up and about and feeling perfectly well. The analysis of the urine passed the 22nd showed a very sudden drop in the amount of sugar and he also was showing symptoms of drowsiness. He would sit in the chair beside his bed and drowse during the morning. It was easy to rouse him, but as he said "he just felt sleepy." During that day I ordered him to be given three cups of cocoa, each of which contained a teaspoonful of sugar. The next day he felt much better and was not as drowsy, and by the next day he seemed to have completely recovered. It is interesting to note that the sudden drop in sugar was coincident with the gradual drop in his weight and that on account of his symptoms when we added cocoa with sugar the output of sugar increased, his weight also showed an increase. The case continued without any change in the diet or his medicine and without any particular symptoms until November 11, when the nurse told me that he was not as bright and active as formerly, although when I saw him he seemed to be about the same as usual. On November 15 he did not get up at all, although he would answer me intelligently, still he was quite drowsy and the output of sugar had very suddenly decreased. He was then ordered four cups of cocoa during that day, to each of which a teaspoonful of sugar had been added. Even with this addition the output of sugar the next day was approximately the same and it was harder to rouse him. During the next night he became comatose and died two days later.

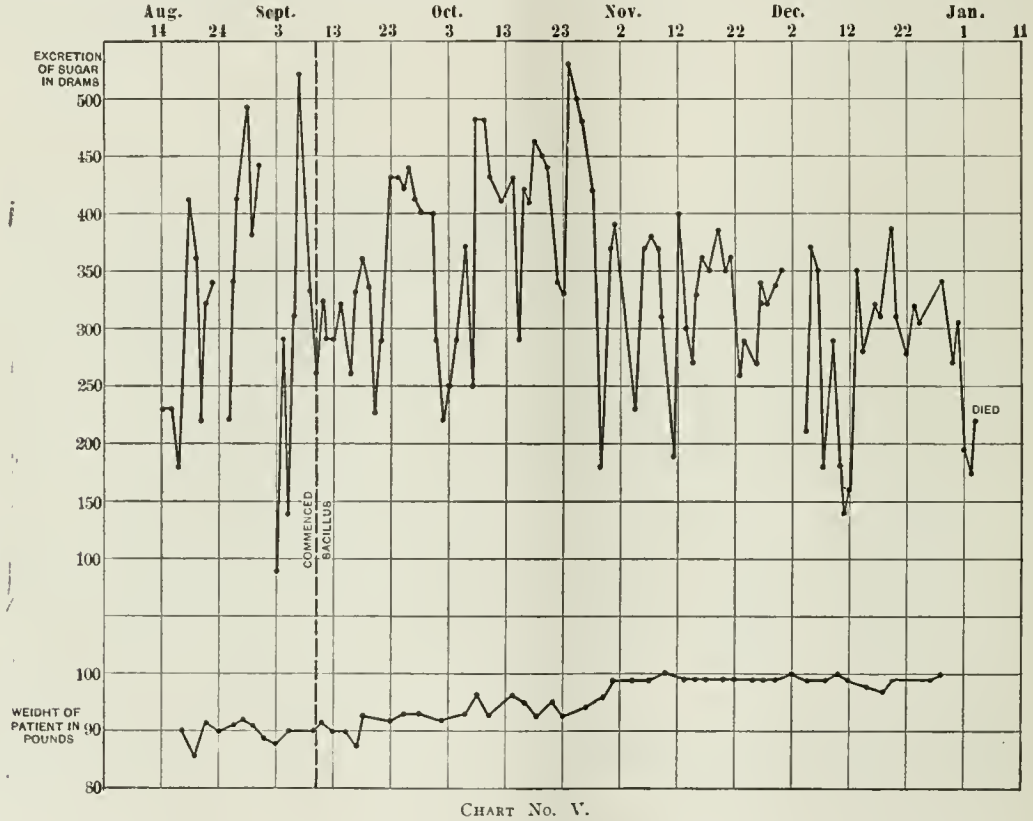

Chart No. V.

Case V.—Glycosuria. Type C. This case was particularly interesting as it was under observation for about a month before beginning with the Bulgarian bacillus. The patient was a girl seventeen years old, rather thin but bright and intelligent. Her family history as regarded sugar trouble was negative. For the past three months she had had a great thirst and passed large quantities of urine. The onset was rather sudden but she could not place the beginning of the thirst more closely than within a period of about two weeks. No attention was paid to her trouble until after she began to lose flesh, which was approximately a month after her first noticing the thirst and polyuria. She then consulted an "advertising institute" where she received some sort of treatment. On August 14, she was assigned to my service and as the preliminary examination showed a considerable amount of acetone and diacetic acid, she was put on a fairly liberal diet. She was allowed milk, eggs, and meat, as she liked, a small quantity of potato or any other vegetable, and a slice of bread with each meal. She was also given ten grains of bicarbonate of sodium each day and her temperature was

taken at two, four, six, and eight each afternoon to see if there were any rise in temperature during the afternoon hours. On August 19 her diet was made somewhat more restricted. She was allowed milk, meat, eggs, thin soup of meat or fish, but for carbohydrates was restricted to one slice of bread with each meal and for green food, peas, lettuce, celery, spinach, with one orange or one grape fruit or two pears each day. The sugar decreased during the next two days, possibly due to the restriction in the diet. This diet was continued until the sudden great drop came on September 2 and 3. At this time she was given twenty grains of bicarbonate of sodium with small portions of any carbohydrate and also a glass of lemonade twice a day, in which were put two teaspoonfuls of sugar. The drowsiness which she had had for two or three days rapidly and entirely disappeared. On September 7 she being apparently in her normal mental condition, the diet was restricted as on August 19 with the addition of one ounce of oatmeal for breakfast and one ounce of cooked rice for supper and the bicarbonate of sodium was reduced to ten grains a day. The sugar was reduced in amount and came back to what apparently was about her normal (300 grams a day). The acetone and diacetic acid were reduced in amount. I had had a correspondence with a physician who had advocated the use of Bulgarian bacillus in cases of glycosuria and he very kindly offered to outline the treatment and diet in this case. On September 10 the patient was given four vials of a preparation of Bulgarian bacilli as follows: the contents of one vial in milk one-half hour before each meal and the contents of a fourth vial in milk a few minutes before retiring at night. She was also given 30 grains of bicarbonate of sodium and was given enough castor oil to cause her to have at least two free evacuations on two regular days each week. The reaction of the stool was taken twice a week and there was never any time during the continuance of the case that the reaction was not acid. There was nothing very particular to say in relation to the continuance of the case. The same general diet was continued throughout the case with the exception of a few minor changes in her diet as advocated by the physician who was advising me about the case. Also the same general treatment was continued except that at times she was given but three vials of the liquide daily instead of four. On September 30 I began fermenting a pint of milk a day with the Bulgarian bacillus, but after taking this for about two weeks it became so thoroughly distasteful to the patient that it was given up. About the middle of October we took away a considerable proportion of the sweet milk which she had been taking. There was also added to her diet list an extra slice of white bread each day. With these slight changes in her diet the case progressed and the output of sugar varied as it does in this class of cases. The high output of October 24 and 25 was due to an attack resembling the grippe. On November 10 and 11 there was a considerable drop with accompanying symptoms of slight drowsiness and some loss of appetite. She was given two cups of cocoa during that day, each of which contained two teaspoonfuls of sugar. The symptoms disappeared the following day and she went on much the same as usual until December 10 when she showed again some slight symptoms of drowsiness and she was given cocoa with sugar. December 11 showed symptoms of slight drowsiness and loss of appetite. She was this time given three cups of cocoa which contained two teaspoonfuls of sugar each. The second day following all her symptoms had decidedly improved and she remained up and about, going out of doors and feeling very well indeed until December 31. On that date she partially lost her appetite and this was followed by a decided decrease in the amount of sugar with signs of impending coma. She was given cocoa three times a day, made with sugar, and in addition was given 60 grains more of bicarbonate of sodium but within two days she was totally unconscious and never roused again. Her weight which had averaged about 90 pounds when she was admitted, had gradually increased to about 100 pounds and remained about there until her death.

Case VI.—Glycosuria. Type C. This is a case of a young boy eighteen years old. His family history negative as regards sugar. His general health had been very good. About four months before I saw him he had been troubled with thirst and polyuria. This continued nearly a month before he consulted a physician. The physician made an examination of the urine and placed him on a comparatively rigid diet. The patient was not careful in regard to his diet, eating bread and sometimes a piece or two of candy. He was sent to my clinic in the early part of October, while the other two cases of this type were being treated. I placed him on the same diet that they were having but without giving him any medicine, either bicarbonate of sodium or the Bulgarian bacillus. He was allowed the same amount of carbohydrate food that the other two cases had, but was not restricted as to the amoun of nitrogenous food which he was allowed. He was also given all the sweet milk he wished each day. On November 9 the urine showed a great diminution in the amount of sugar and he was complaining of lassitude. He was given that day two cups of cocoa with two teaspoonfuls of sugar in each and was also given an extra slice of white bread. Two days later, apparently having returned to his normal condition, he was again placed on the same diet as the others. On December 24 as he was very anxious to return to his home for the holiday, I allowed him to do so. The patient is still supposed to be on the same diet as he was taking while at the hospital. I see him once a week but I shall not record his analyses as I do not consider that he is adhering strictly to the diet and under these circumstances the analyses would give us no reliable data. He reported on February 17 and seemed to be as well as he was during his residence at the hospital.

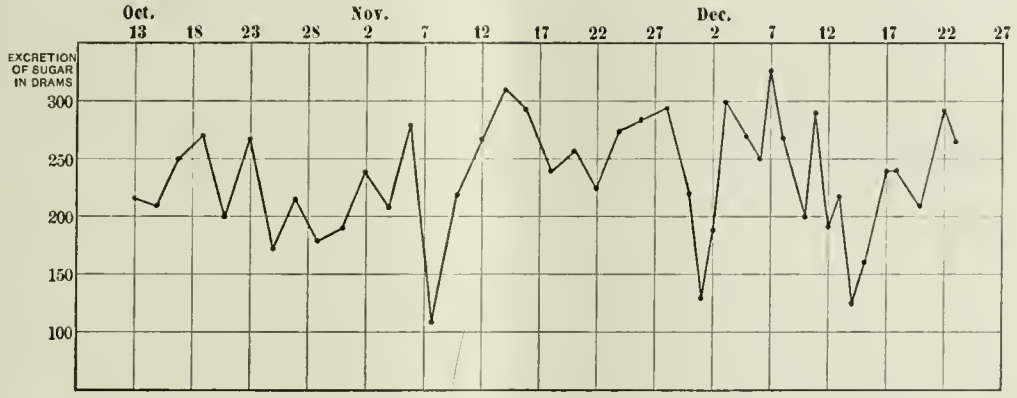

Chart No. VI.

These three cases were all of the same type, all under treatment at the same time and all received virtually the same diet. Two of these received the Bulgarian bacillus (one of them in addition received daily doses of sodium bicarbonate) and one of them received the same diet, but was not given any medicine. The two who received the Bulgarian bacillus are both dead, although this fact I do not think we ought to use as an argument against the use of the Bulgarian bacillus, but we can say that in these two cases the Bulgarian bacillus was apparently of no benefit.

---

**Abdominal Aortitis.**—J. Colombe states that whatever the cause of this condition the chief symptoms are pain and gastrointestinal disturbances. Other symptoms are epigastric pulsation, reflex phenomena, such as vertigo, dyspnea, attacks of syncope, and sialorrhea. The physical signs are tenderness on pressure over the course of the abdominal aorta, enlargement of the latter, and its deviation to the left, increased mobility of this artery, and occasionally murmurs.—*Gazette des Hôpitaux.*

# OBSERVATIONS ON SOME CLINICAL FEATURES OF PAINFUL OXALURIA.

By B. G. R. WILLIAMS, M.D.,

PARIS, ILLINOIS.

Down through the history of medicine we note occasional references to the possibility of injury and irritation resulting from the passage through the urinary tract of certain inorganic sediments, notably the crystals of calcium oxalate. However, the diagnostician has been loath to acknowledge that symptoms arising from these conditions may be explained without the presence of another or other lesions. For example, Maguire[1] would rather believe that he effected the solution of an oxalate stone in a ureter by aid of diacid-sodium phosphate—an oxalate stone, mind you, which failed to show a shadow, than that the clinical features of the case could have been explained alone by the fact that the crystals of this substance were present in the voided urine. Authors of texts upon urology and surgery approach the subject apparently in fear and trembling; and either make a few indirect remarks or else slyly omit it. Even Cabot,[2] though somewhat braver than the rest, hesitates to attribute to the condition, the emphasis which it deserves.

In a former communication[3] I emphasized the fact that these crystals may certainly give rise to symptoms quite similar to those caused by renal or ureteral calculi; but that the two conditions may be differentiated by the uranalysis and by the *x*-ray picture. Further, I attempted to show that while the latter demands surgical interference, the former falls into the realms of internal medicine. To this condition I applied the term painful oxaluria (*oxaluria dolorosa*).

These remarks may serve well for an introduction to the several case reports and observations which I am about to add:

Case I.—Miss A. G., a farmer's daughter, age 25 years, with a negative family and personal medical history, complained of considerable distress in the lumbar area, of several years' duration. The pain was almost continuous, and though at times very severe, she had never been bedfast. The "misery" had never been referred to the abdomen or the pudendum. Both sides were equally affected (an item which makes calculus very unlikely). She did not believe that her urine had ever contained blood. Examination revealed a normal temperature, pulse and respiration frequency. The abdominal examination was entirely negative. She stated that the pain was quite as likely to be severe in the early morning as at night; and examination ruled out the possibility of flat-foot. Visceroptosis was not diagnosable; though one physician had told her that she had a floating kidney. (She said that she had been treated as a "neurotic"). A blood examination failed to throw any light upon her condition; but the urine contained many calcium oxalate crystals, large numbers of which were minute and imperfectly crystallized, often acicular or with sharp points. Questioned as to the season in which her distress was most intense, she quickly answered, "In the summer." The diagnosis was, therefore, rather clear; but we thought it best to take also an *x*-ray picture. This was negative. Repeated examinations of the urine failed to show pus or mononuclear cells, and failed to identify tubercle bacilli. Invariably were the oxalate crystals found; and these were present in the largest numbers when the pain was most severe. Blood cells were never found, but hemoglobin was frequently identified.

The treatment followed in this case, was very similar to that advised at the end of this chapter. The urine was scarcely acid, but the acidity increased as sodium phosphate was exhibited. Apparently the treatment was not in vain, for the irritation almost instantly disappeared. I was somewhat surprised however, to find upon a subsequent examination that the oxalate crystals had given away to the whetstone forms of uric acid, and that these were present in the freshly voided urine. The acidity became tremendous. Dietetic treatment was continued but the phosphate left off. Symptoms have not yet reappeared; although I have noted that these may be long preceded by reappearance of the oxalates. The patient does not adhere closely to her diet, being convinced that she is cured. Time will solve this problem much better, however.

The chemical relation between oxalic and uric acids is so close that I am not surprised to note the vicarious phenomenon described above; although I am scarcely able to explain just what part, if any, the phosphate treatment played in the matter. The change was effected when the urine became highly acid. It may occur more readily here, I should think, than in diabetes where the total oxalic acid is vicarious (very often) to glucose. Parenthetically I have often noted that when the glucose in diabetes decreases, large numbers of uric acid crystals may appear. Is there an interrelation between these three bodies: if so, what is this?

Case II.—Mr. G. S., a farmer of 42, came to me for a diagnosis. Examinations were negative save for the finding of large numbers of small oxalate crystals and red blood cells in his urine. When blood was absent from his urine, he suffered but little distress, but at these times crystals could be found only with difficulty. Upon what did this man's pain depend? The answer is clear to me; but unfortunately the case cannot be detailed quite so thoroughly as the one above. The patient refused either to pay for an *x*-ray examination or to follow a diet which would have possibly aided us in the diagnosis, stating that he wanted some medicine which would "dissolve the stone." Although he had tried most of the stone-solvents, apparently he was not yet discouraged.

A calculus may have been lodged in the renal pelvis or ureter. The distress was typical of such a condition; but the uranalysis supplied another explanation. Still calculus and oxaluria may have coexisted. The former to have been present, would almost necessarily have been rich in oxalate salt, and cast a dense shadow. Had this man been in a hospital, the question could have been solved. Disgusted with the fact that we would not attempt to dissolve his stone, he decided to consult an osteopath who assured him that he could "manipulate it."

Case III.—A. S., a boy of ten with a previous negative medical history except that several years ago, he fell from a first story window upon his head. No bad effects were noted at this time. But soon after this he began to suffer from a nocturnal enuresis, which constantly grew worse. At the time of examination he voided urine into the bed several times each night. His urine "irritated him" and often dribbled. At times during the day his bowels moved without his knowledge. Spanking had been tried without success. A rather complete physical examination, including a thorough study of his nervous system, revealed nothing of diagnostic value, except a "neurotic" temperament. There was no phimosis and no evidences of hypothyrea. Some urine which was collected half an hour after the noonday meal, showed a specific gravity of 1034. Could this be a case of neurogenous diabetes resulting from injury of the medulla in the fall mentioned above? I fully expected to find glucose; but this was absent. When, however, a specimen of the unfiltered urine was held in the direct sunlight and set in motion by twirling, a curious phenomenon was noted. Each crystal, notwithstanding its microscopic smallness, caught the light, flashing minutely as it appeared and disappeared. And thus the impression of finely pulverized glass was gained. Under the lower powers of the microscope, the identity of these crystals could not be distinguished; but when the higher objectives were used, the following picture was seen:

Some of the crystals were octahedral (so-called envelope forms) and were often large and perfectly constructed. While such first caught my eye and identified the nature of the sediment, a close inspection showed the presence of other forms. There were many small crystals, some perfectly designed, but many others exhibiting evidences of imperfect crystallization. Here and there an axis was greatly lengthened, and many an acicular structure observed. Very seldom was a true raphus seen: if such had been formed, it had most likely been crushed by the powerful muscular walls of the ureter. Irregular forms were frequently noted; but invariably were the angles acute, and the points and the edges apparently *sharp*.

Two questions at once arose: (1) May all the symptoms be explained by the presence of these crystals (their continued presence in the freshly voided urine)? (2) If so, upon what shall we base our treatment?

Apparently the first query could be answered in the affirmative, and the case observed pending the results of the second. At once, there presented themselves two problems not so easily solved: (1) Was or was there not an actual increase in the total amount of oxalic acid excreted in the

twenty-four hours; and what bearing if any did this have upon the treatment? (2) Where and how did the precipitation of the insoluble crystals occur; and what bearing, if any did this have upon the treatment?

The Baldwin method showed that the increase in oxalic acid was absolute. We could at least assume that while this fact was not the only one of importance in the disposition of the case, it was perfectly evident that we would more likely be able to decrease the precipitation of the crystals if we could but decrease the substance which went into their makeup. This phase of the situation could be realized if we excluded food containing oxalic acid and (to a less extent) all carbohydrates and could prevent or check intestinal fermentation of the carbohydrates.

We had good reason to believe that precipitation took place in the ducts of the uriniferous tubules or the renal pelvis. Otherwise we could scarcely be able to explain the symptoms in cases like Nos. I and II. How was this precipitation accomplished? This was not entirely clear; and here comes a gap in our treatment. But in my former communication, I proposed that the reaction of the urine may have much to do with this precipitation. I am scarcely prepared to lay as much stress upon this as formerly, but believe that a neutral or alkaline urine may favor the deposit and that this may also occur in a highly acid urine. However, acids are doubtless usually indicated. A sterile but cold flexible catheter was passed daily for a week; and this seemed to aid in the treatment, exerting a favorable influence upon the mind of the boy. The reader may suggest that it accomplished all that was realized. At any rate the relief was prompt.

In this connection I desire also to record a case of nocturnal enuresis suddenly appearing at the age of four and which prompted the parents to seek advice. In this case there was also some dribbling during the day. The urine, though fresh, contained many whetstones of uric acid. Did these cause the irritation? The trouble was promptly relieved by cathartics and diuretics.

Case IV.—S. T., a boy of four with a history of bladder irritation and pyuria following typhoid fever (?). The urine had been submitted to several pathologists, all of whom had reported pus and oxalates. One of these men had read my former communication upon the subject of painful oxaluria, and suggested this diagnosis. However, I pointed out in that article that uncomplicated painful oxaluria was rarely associated with pus and microorganisms. The irritation is a "moving one," a large surface is damaged and germs do not obtain a foothold so easily as in the rough and unwashed caverns of the calculus.

What, indeed, were these urinary findings? I discovered pus cells in large numbers and microorganisms but no blood cells or hemoglobin. True, I found crystals resembling very much the oxalate envelopes. But the number was not large even in centrifugalized specimens, and they were of almost unvarying size and shape. A closer study revealed forms not octahedral but prismatic with square facet presenting in the foreground and oblique terminal surfaces. Microchemical tests with acetic acid showed that these crystals were easily dissolved, thus finally excluding calcium oxalate crystals. This urine was highly alkaline and was undergoing ammoniacal fermentation. These crystals were those of ammonio-magnesium phosphate. The pathologists had failed to identify the sediment by virtue of the fact that the typical coffin-lids were absent. A later examination revealed large numbers of eroded or sledge forms of these crystals.

*Modern Theories Concerning Oxalate Metabolism.*—I have but little to add to those statements which I made several months ago, and perhaps some to retract. Oxaluria may result from ingestion; but a persistent oxaluria does not arise from any such cause. An oxaluria to cause symptoms doubtless must always be persistent. I will concede that a question exists in regard to this, however. Beyond a doubt persistent oxaluria (*true oxaluria*, where estimation of the oxalic acid shows an increase) is associated with a perverted carbohydrate metabolism, but attempts to make this clear have been unsuccessful thus far. In oxaluria dolorosa (we must distinguish *clinical oxaluria*, where the urine when voided contains oxalate crystals even though the total urinary oxalic acid may not be increased) there are two other factors:

1. Precipitation of the insoluble oxalates in the urinary passages. Fürbringer has shown that the urine may contain a large amount of oxalic acid and yet no precipitation of the crystals occur. But as I have previously declared, it is useless to attempt to treat a *clinical oxaluria*, simply by reducing the oxalates though this may, of course, aid. We must prevent the formation of the crystals in the urinary passages. Once formed, these crystals probably cannot be redissolved.

2. *Persistent* precipitation of the insoluble oxalates in the urinary passages. The injury must be continued. Based upon my observations in these cases, I am tempted to go a bit further—that this crystallization in oxaluria dolorosa is rarely perfect but minute acicular and irregular forms are frequently seen.

For other points in this connection, I shall refer the reader to my former communication, especially with reference to other examples in which mechanical injury by the oxalate crystals, notably the raphides of certain plants, as the dumb cane, occurs.

*The Oxalurias Defined and Classified.*—1. *True Oxaluria.*—I have pointed out the fact that the oxalic acid of the urine may be increased and yet no precipitation of crystals occur before the urine is voided. The term is a technical one and has nothing to do with my subject except, perhaps, so far as the treatment is concerned.

2. *Clinical Oxaluria.*—But in another class comes clinical oxaluria. Here the oxalic output daily may or may not be increased, but the distinctive feature is the fact that insoluble calcium oxalate crystals are precipitated somewhere in the urinary tract, and may be found in the fresh urine. We have several forms of clinical oxaluria, among which may be mentioned:

(*a*)—*Simple Clinical Oxaluria.*—Condition usually temporary. Crystals may or may not be well formed. Crystals must be found in freshly voided urine.

(*b*)—*Painful Oxaluria.*—It is scarcely necessary to define or describe this condition further than I have done already or shall do before the end of this article.

3. *Deposit of Oxalate Crystals in Urinal.*—This, of course, is not an oxaluria. When the diacid-sodium phosphate which normally holds the oxalates in solution is neutralized by fermentation the deposit occurs.*

*The Uranalysis.*—Briefly a few points must always be kept in mind:

1. Clinical oxaluria cannot be diagnosticated unless the sediment proves to be crystalline calcium oxalate. The crystals may be detected but not differentiated by holding the specimen in the direct sunlight. The crystals can rarely or never be differentiated by the lower microscopic objectives. Even under the higher powers they may be almost exactly counterfeited by the triple phosphates. If in doubt apply the microchemical test.

2. Clinical oxaluria cannot be diagnosticated by the examination of any but a freshly voided sample of urine. Normally, calcium oxalate is held in solution by the diacid-sodium phosphate; and no crystals are noted in such a urine unless the ingestion has been great indeed. But when the urine ferments, the phosphate is neutralized and the oxalate is precipitated.

*Entirely foreign to our subject, is the term, *vicarious oxaluria*, a condition noted in diabetes where the fluctuations in the amount of oxalic acid appear to be inversely proportional to the amount of glucose.

3. True oxaluria is detected by chemical estimation of the total oxalic acid each twenty-four hours. Clinical oxaluria is diagnosticated by microscopical examination of the freshly voided urine. The discrimination is an important one and is not made in texts.

4. A clinical oxaluria to be painful must perhaps be persistent. Several examinations should be made to determine this point. It is possible that an oxaluria of a very short duration may cause symptoms in some individuals. A painful oxaluria is quite likely to become aggravated in the summer when a vegetable diet adds more oxalates to the already embarrassed metabolism.

5. To prove painful oxaluria it is necessary to rule out calculus by a proper *x*-ray examination, and to rule out any other condition which may be giving rise to the symptoms. We must not be too anxious to diagnosticate oxaluric dolorosa; but upon the other hand, we must not be too free with the knife when it is evident that such is the condition. An *x*-ray picture can always be obtained from an oxalate calculus. Webster[4] has ventured that the name "oxaluria" can hardly be dignified as a definite pathological entity. Perhaps not, but then again perhaps. Now and then we have cut down upon a stone which was not there when a brief study of the case would have led us to have hesitated.

6. To prove painful oxaluria it is almost necessary to prove some relation between the amount of sediment and the severity of the symptoms. Invariably it happens that immediately subsequent to the attack tremendous amounts of this may be found in the urine.

7. Blood or hemoglobin likewise may frequently accompany the attack. The red cells, as I pointed out in a former communication, are likely to be well preserved. The blood is not laky. Upon the other hand the presence of pus and of microorganisms, except in the very chronic cases, should lead us to doubt the diagnosis of oxaluria dolorosa. Examine catheterized specimens, search for the gonococcus and inoculate guinea pigs for evidences of tuberculosis.

8. In oxaluria dolorosa the normal acidity of the urine is usually disturbed, though such an item is of but little differential value.

9. In oxaluria dolorosa the crystallization is quite likely to be minute, imperfect, and acicular. Invariably a few perfect crystals are present and these aid in the identification of the sediment.

10. As a circumstance of exceedingly great differential value in the consideration of possible calculus is the fact that the pain in clinical oxaluria is usually bilateral; *i.e.* it is quite as intense upon one side as the other.

*Treatment.*—I have but little to add to those principles which I laid down one year ago. The object is not only to reduce the amount of food containing oxalates and to correct any processes which may be changing carbohydrates to oxalic acid in the gastrointestinal tract, but to prevent if possible the precipitation of oxalates in the urinary passages.

As regards foods containing oxalic acid it may be said that oxaluria does not depend upon this cause alone, but reduction of these may aid somewhat in the treatment. To correct matters in the gastrointestinal tract, I can recommend nothing more efficacious than a routine course of laxatives and water drinking. I regard sodium phosphate very highly in this connection because it may also supply in part the diacid salt which normally holds the calcium oxalate in solution in the urine.

But how are we to prevent the precipitation of the insoluble oxalates in the urinary passages? for once precipitated, they can scarcely be redissolved. It is possible that correcting the acidity (if neutral or alkaline, giving diacid-sodium phosphate: if highly acid, reducing this somewhat by alkalies) may aid in part. In some cases this appears to be a method of worth; but I am by no means as enthusiastic concerning its merits as I was several months ago. The treatment of oxaluria dolorosa has by no means been perfected.

The diet list which I am about to recommend is based in large part upon experience in these cases rather than upon theory, and must be modified somewhat to suit the patient in mind. It should be rigidly carried out for a couple of weeks, possibly longer, at least until it is evident that it will give no benefit. I have seen fit to prescribe water according to directions similar to those given below that I may be assured whether or not enough of this is really being taken. The cautions concerning drinking at night are noted, and apply particularly to cases of nocturnal enuresis apparently due to the passage of oxalate crystals through the urinary tract. Carbohydrates should be decreased, as excessive amounts may favor a fermentation resulting in formation of oxalic acid.

*May Eat in Desired Amounts.*—Any kind of meat, but this should not be fried. Oysters, fish (not fried), beef, mutton, chicken, game, salads, peas, eggs, and milk. Milk, skimmed milk, boiled milk, and buttermilk may be taken in large amounts. It may be well at the onset to use a milk diet as a basis. Water should be taken in tremendous amounts. If the patient suffers from nocturnal enuresis, water should be avoided in the evening. Lithia tablets may be added to the water. It may be prescribed as follows: Drink a cup of warm (almost hot) water before breakfast, plenty of water during this meal and a cup of cold water after breakfast. Drink several glasses of water during the forenoon. Drink a glass of water before dinner, plenty of water during the meal, and a glass of warm water after the meal. Drink an occasional glass of water during the early afternoon.

*May Eat in Moderate Amounts.*—Good bread may be eaten in moderate amounts. The same applies to butter, cheese, hominy, rice, toast, oatmeal, battercakes, and crackers. Beans and potatoes should be eaten in very small amounts, or avoided if possible. Soups may be taken in large amounts (except at supper time in nocturnal enuresis). When preparing soups avoid vegetables named below. Pies, cakes, and fried dishes should be almost avoided.

*Avoid Entirely.*—Candies, syrups, ice-cream, tomatoes, pieplant, oranges, cabbage, cocoa, tea, pepper, grapes, sorrel, carrots, string-beans, garlic, asparagus, celery, spinach, plums, and strawberries. Avoid vinegar. Eat but very small amounts of apples, pears, peaches, and melons.

*Conclusions.*—I shall not detail a list of conclusions inasmuch as but one thought is to be emphasized; viz. the year of 1912 added but little to our knowledge of the oxalurias; but this does not excuse the surgeon from overlooking the fact that when the *x*-ray fails to reveal a stone, and when the symptoms and signs vary in intensity directly with fluctuations in the number of crystals of calcium oxalate appearing in the freshly voided urine, such features deserve very careful attention. As a path-

ological entity, painful oxaluria (*oxaluria dolorosa*) bids strongly for a place in our texts and for our sober consideration. The condition may not be a common one after all, but a study of the question has convinced me that it is not an impossible one. Time will solve the question. But in the meanwhile, why this reluctance? Is it beneath our dignity to investigate, merely because the name "oxaluria" has not yet been dignified?

## THE PRESENT STATUS OF THE TUBERCULIN TESTS.*

BY CHARLES B. SLADE, M.D.,

NEW YORK.

CHIEF OF CLINIC IN GENERAL MEDICINE, AND LECTURER ON PHYSICAL DIAGNOSIS, UNIVERSTY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; EXAMINING AND VISITING PHYSICIAN TO OTISVILLE SANATORIUM.

My first recollection of the use of tuberculin for the diagnosis of tuberculosis, refers to the time when I was an interne in Bellevue Hospital about seventeen years ago. It was then that we injected, subcutaneously, five to fifteen milligrams of the proteid glycerin extract of tubercle bacilli, or Koch's old tuberculin. This was done in two or three cases, wherein the diagnosis of tuberculosis was suspected, but could not be settled by other means. A few days after the injection there was no room for doubt—they certainly had pulmonary tuberculosis, and in a very active form. Our experience was not peculiar, many others observed these severe reactions, and such large initial dosage was quickly abandoned.

At the Adirondack Cottage Sanatorium, for several years, all patients without tubercle bacilli in their sputum, were required to undergo the subcutaneous tuberculin test. So far as I know, this may still be the routine practice in that institution. The method which I understand they employ is to begin with half a milligram, increasing the dose gradually, in subsequent injections, to one, two or three milligrams until a positive reaction is obtained, or until 10 milligrams or more have been given at one dose. This is the method now employed by those who use the subcutaneous test. The maximum dose varies in different hands, from three to ten or twelve milligrams. Four or five days should elapse between injections.

So capable an observer as Dr. Lawrason Brown, after a wide experience, said that he had come to believe that a failure to react to even 10 milligrams of old tuberculin, given subcutaneously, does not exclude clinical tuberculosis. He further stated that he had observed many cases in which the results of tuberculin reaction added only confusion to the clinical data. It has been said, by some observers, that many patients who have experienced rather severe reactions seem to feel generally better after the reaction subsides. I am inclined to believe that this postreactional improvement in the patient's subjective symptoms is really only an unconscious comparison with the great discomfort experienced during reaction. I think it is rather broadly agreed that, in adults and perhaps in children beyond the age of five years, a positive reaction is of no practical clinical value, and yet this is the result which is liable to cause havoc. It has been clearly demonstrated that it is only necessary for an animal or patient to have had, at some time, a bacillary infection, with or without any resulting lesion, for tuberculin to cause a positive reaction, however administered. It has been said that a failure of the subcutaneous injection of tuberculin to cause a reaction in a tuberculous individual is due to either an absence of receptors at the site of the lesion or the presence of antibodies in the blood. This opinion sounds reasonable, when applied to those far advanced cases, with extreme general depletion, who fail to react; but, I do not see how it can explain the occasional failures to react in some moderately advanced cases, where the diagnosis is otherwise provable, and the patient's general nutrition and vitality are good.

It was in May and June, 1907, respectively, that Wolff-Eisner and Calmette called attention to the reactions obtained by dropping a half or one per cent. solution of tuberculin into the eye. This conjunctival test, called the Calmette test (apparently because Calmette seems to have been a better talker than Wolff-Eisner, who first announced the reaction) has in recent years been abandoned by most observers, in favor of the von Pirquet skin test. The Moro test, which is obtained by frictional application of a tuberculin ointment to the skin, is not very generally employed, because it is less accurate and slower in reaction.

Dr. Rathbun and Dr. White have supplied me with a statement regarding some thousand or eleven hundred cases in which we applied the Calmette and von Pirquet tests in the Otisville Sanatorium, upon which the following is based. Our experience with the Calmette test covered about six hundred or seven hundred cases. No eye tests were made on anyone presenting, on careful inspection, anything abnormal in either eye. A drop of a half per cent. suspension of old tuberculin was instilled into the eye with an eye dropper. The eye was inspected each day for the reaction for the next three days. Reactions were graded *slight, moderate,* or *severe.* If no reaction or doubtful reaction occurred, a one per cent. solution was put into the other eye one week later and this eye was inspected daily for three days. There were no untoward results from this test in our experience. We had a few reactions that were rather more severe than we liked to see, but they cleared up without any damage to the eye. In one case the inflammatory reaction lasted ten days or two weeks. Usually the reaction lasted only five or six days. No constitutional reactions were noted in our experience, although they have been reported in the literature.

As to the interpretation of our results with the Calmette test, I would say that in the definite and active cases with positive sputum the reaction was constantly positive, except in a few very advanced cases. In the fairly definite cases, where the sputum was negative, the reaction was almost uniformly positive. In the group of cases where the diagnosis was considered very doubtful, there was no uniformity in the Calmette reactions. However, in the latter group, when the reaction was negative, we felt that it was confirmatory evidence, of some value, that the condition was not tuberculous. Regarding positive reactions, we could not see that

*Read before the Association of Physicians Attending Tuberculosis Clinics, New York City, April 9, 1913.

they were of any clinical value, from either a diagnostic or prognostic point of view.

With the von Pirquet test our experience covered about four hundred cases. Our method was as follows: The forearm was cleaned with alcohol. Three drops of tuberculin were applied to the arm about one and one-half inches apart. One drop was crude, one was 25 per cent., and one 1 per cent. With a small scarifier introduced through the drop, the epidermis was scraped away, much as in the method of vaccination. A control was made nearby with sterile salt solution. The extent of the reaction was determined by the size of the inflammatory areola that developed.

I should mention, parenthetically, that crude tuberculin put into the peritoneal cavity of lower animals has produced lesions similar to those produced by the injection of live tubercle bacilli into the peritoneal cavity. Also that von Pirquet has seen crude tuberculin, when used in his skin test, produce a tubercle-like lesion at the point of application. We never observed any such lesions in our work at Otisville.

Our results made us feel that the von Pirquet is more sensitive than the Calmette test. It certainly gave a higher percentage of positive reactions. Thus, it would seem that a case negative to von Pirquet is more likely to be nontuberculous than one which was only negative to Calmette. I notice that, in his report, which I recently asked for, Dr. White uses the expression "confirmatory value" in connection with the negative results in the von Pirquet test. This shows that he still places the bulk, if not all, of his reliance in other methods of diagnosis. I should add that we observed no constitutional reactions to the von Pirquet tests.

We have had very little experience with the tuberculin reactions in children, where it is said to be of most value. Some have said that, under five years of age, a positive reaction means active tuberculosis.

Last week, at my request, Dr. J. J. Shea, House Physician of the Third Medical Division of Bellevue Hospital, applied the von Pirquet test to twenty-four adult patients in the medical wards. All of these patients were free from any clinical suspicion of tuberculosis in the personal or family history. Among these cases were instances of almost all the diseases commonly found in a general medical ward, except tuberculosis. Several had nephritis, several myocarditis, two had syphilis, two gout, several rheumatism, two had gastric ulcer, peripheral neuritis, chorea, bronchopneumonia, septic endocarditis, intermittent claudication, and chronic endocarditis made up the remainder. Although none of these twenty-four patients had ever been suspected of having tuberculosis in any form, twenty-two of them gave a positive reaction to von Pirquet, and one of the other two became faintly positive after seventy-two hours. Thus leaving one certainly negative result in twenty-four people clinically nontuberculous.

For comparison with these, I have had Dr. Rathbun try the von Pirquet and Moro tests on thirty cases in the Otisville Sanatorium. Ten patients, with negative sputum, in whom clinical data and physical signs are sufficient to justify a diagnosis of pulmonary tuberculosis, were subjected to the von Pirquet test. At the end of forty-eight hours six of these showed a positive reaction and four were negative. At the end of seventy-two hours three of the four negative cases had developed a positive reaction. Thus the ultimate result in these ten cases of clinical pulmonary tuberculosis, of slight extent, was 90 per cent. positive to the von Pirquet test, again 96 per cent. positive in the clinically nontuberculous in Bellevue Hospital. In both groups they were bacteriologically negative. I realize that individual difference, in two seperate men reading the reactions in the two instances, might account for part of this strange result. In ten cases, clinically similar to the ten already referred to, the Moro test—fifty per cent. tuberculin ointment in a lanolin base—was applied. In these ten patients, clinically tuberculous, only two gave a positive reaction to the Moro test. In five advanced cases of pulmonary tuberculosis, five positive reactions to the von Pirquet test were obtained. In five advanced cases, in which the Moro test was used, one was positive, one faintly positive, one showed a few red spots, one was doubtful, and the other one was negative.

Barring children under five years of age, with whom I have had little experience so far as the various tuberculin tests are concerned, I will attempt to summarize, or state as briefly as I can, what is, in my opinion, the present status of these tuberculin tests in diagnosis. The Moro test, from a clinical point of view, is so unreliable that it is a waste of time to apply it. The subcutaneous injection of tuberculin is undoubtedly the most reliable from a scientific point of view. Clinically it is not absolutely reliable, even when negative. Severe reactions in a considerable number of cases are unavoidable. These reactions may, and do in some cases, cause irretrievable harm; therefore it is not justifiable to employ this method as a diagnostic routine. The Calmette test is probably harmless when applied with unfailing care in the choice of cases; but since it is capable of doing injury to the eye, and since it seems to present no advantage over the von Pirquet test, it should not be employed as a diagnostic routine. The von Pirquet test is undoubtedly harmless and is the only one in which I can see no objection to its use as a dignostic routine, although it is of very little practical value beyond the age of five years. In some rare cases, where the diagnosis cannot be reached by any other means and yet, for the patient's interest, it is imperative to either affirm or disprove the presence of tuberculosis, it is justifiable to apply, cautiously, the subcutaneous injection of tuberculin for diagnosis. This applies especially to disease of joints, where the focal reaction can be more easily observed.

In employing any of these reactions I feel that we should have a broad enough judgment to realize that it is not so much our obligation to determine whether or not a person has tuberculosis, but whether or not his tuberculosis has become a *disease* clinically. When we consider what a large percentage of the human race are infected with the tubercle bacillus at some time, the multiplicity of hypersensitive methods at our disposal for detecting it, and the great eagerness of many physicians to discover it, the wonder is that anyone escapes the diagnosis.

## THE BILE IN THE LIGHT OF NEWER TEACHINGS.

THE humoral pathology of the ancients accorded to the bile an important place in the vital economy. The words "melancholy," "atrabiliar," "choleric" are surviving relics of primitive physiological teachings. There came a time, however, when coincident with the development of modern anatomy considerable doubt was cast upon the value of the liver and its important secretion in the workings of the body. But the development of experimental physiology during the past half century has shown that the bile has many important functions. The real nature of some of these is still veiled in obscurity.

Without describing the properties which are familiar to every student of elementary physiology, it may suffice to point out that the chapter concerning the functional significance of the bile is not a closed one. There have been many obscure problems wrapped up in its multiple capacity as an excretion and as an important digestive fluid. Within recent years these problems have been attacked by many investigators, but no one has contributed more to their solution than has H. Roger of Paris, who presents a discourse on the subject in the *Universal Medical Record,* April, 1913. He states at the outset that modern workers have shown that although the bile does not possess any direct power as an enzyme, nevertheless, it has a "zymosthenic" influence, inasmuch as it increases the activity of ferments derived from other sources. It enhances the starch-splitting function of the pancreatic juice and activates the lactase of the intestinal secretion. It also exerts a tractor influence, serving to draw forth certain ferments contained in the cells of the intestinal epithelium. The author, in conjunction with H. Chabanier, has shown that the bile is particularly instrumental in evoking invertin from the intestinal cells.

The function of the bile with reference to the absorption and digestion of fats is alluded to. Bile increases the lipolytic power of the pancreatic juice. It favors saponification. It aids in the absorption of fats. These facts have all been clearly established and have been recognized by physiologists for a long time. But according to recent experiments performed by Roger the bile has other important functions. It plays a part in the digestion of proteins. These tend to form in an acid medium certain insoluble compounds with bile. The precipitates thus formed redissolve in an excess of bile. The actual purpose of this precipitation and redissolving is as yet obscure.

The failure of bile to reach the small intestine, whether caused by an obstruction in the biliary passages or by an actual cessation of the secretion of bile, gives rise to a series of phenomena that have been recognized for a long time. "Acholia" was the name first applied more than two decades ago by Cheadle to a condition in which the stools are colorless, contain an excess of fat, and are markedly offensive. The absence of bile from these stools naturally gave rise to the inference that the bile performs the important function of preventing intestinal putrefaction. But Roger now shows that bile is not an antiseptic. When added to broth cultures it does not prevent the proliferation of bacteria. How then can one explain this contradiction, which Roger designates "the paradox of intestinal acholia?" This observer has shown that although bile has no antiseptic power, it nevertheless checks putrefaction by "selectively favoring the development of the less active organisms and, very specially, by modifying the functional activities of such bacteria as do flourish." One of the microorganisms whose propagation is favored by the bile is the colon bacillus, while the growth of the anaërobic agents of putrefaction is inhibited. In *La Presse Médicale,* October 2, 1912, Roger has shown that bile exercises also an antitoxic function by neutralizing certain poisons arising from intestinal putrefaction. The symptoms of "biliousness" resulting from a defective secretion of bile are thus adequately explained.

Another important function of bile hitherto unrecognized is its action with reference to mucus. Mucin is coagulated by a ferment—mucinase—contained in the cells lining the intestine. Bile inhibits the action of this ferment, with the result that the mucus contained in the upper part of the intestine is present in a fluid state. When mucus coagulates it does so in the lower part of the intestine where there is the least amount of bile. In fact, Roger attributes the formation of the pseudomembranes in mucomembranous enteritis partly to biliary insufficiency, the other factors being an excess of mucus and an excess of mucinase. From these facts there is drawn a deduction of therapeutic importance, namely, that the administration of ox-gall is indicated in these cases. Apart from its effect in preventing the formation of the pseudomembranes, the bile would stimulate the function of the liver and the peristaltic action of the intestinal wall.

There can be no doubt that Roger has made a material contribution to both physiology and clinical medicine, by emphasizing the multiple rôle played by bile with reference to the digestion of starch, sugar, protein, and fat; with reference to its antiputrefactive and antitoxic functions; and with reference to certain properties, hitherto unsuspected, in controlling the physical condition of the intestinal mucus. The bile thus provides an illustration of the wise economy of nature in imparting many different functions to one digestive secretion.

## DRUG STANDARDIZATION.

Sufficient attention has not been paid in the past to the very important subject of drug standardization. It is obvious that unless measures are taken to prevent the adulteration and sophistication of drugs their therapeutic and physiological value will be very considerably impaired. Indeed, there are many points which enter into the question, which can be settled in a satisfactory manner only by the establishment of a uniform system of drug standardization. A paper dealing with the subject was read at the thirteenth annual meeting of the American Therapeutic Society by Dr. F. A. Stewart with the collaboration of Drs. A. Parker Hitchens, W. F. Elgin, Charles E. Vanderkleed, and P. C. Pittenger (*Monthly Cyclopedia and Medical Bulletin*, January, February, and March, 1913). Up to the time when the pure food and drugs act of June 30, 1906, was passed, conformance with the standards of the United States Pharmacopeia on the part of the manufacturers was purely voluntary. Since that time it has become compulsory and manufacturers recognize its authority. But as Stewart points out, there is another class of manufacturers dealing with materia medica products, the retail druggists, who are interested in the question of standardization as applied to so-called galenical preparations, and for a time many of these opposed the reform. However, their objections were finally overcome, and standardization was extended more generally to galenical preparations. The results proved so satisfactory that the convention of 1900 resolved that the committee of revision "append assay processes to as many of the patent drugs and preparations made therefrom as it may be found possible, providing that the processes of assay are reasonably simple, both as to methods and apparatus required, and yield fairly uniform results in different hands." This led to the introduction in the present Pharmacopeia of assays for twenty more drugs and their thirty-seven galenical preparations. There are several potent and important drugs which do not admit of standardization by chemical assay and are not included in the list. Among these are digitalis, ergot, cannabis, and strophanthus. During the past two decades physiological or pharmacodynamic methods have been sufficiently perfected to warrant the introduction of more of them into the Pharmacopeia now undergoing revision. There are very wide differences in the amounts of active principles in vegetable drugs, such as digitalis. The tinctures of strophanthus on the market, according to Edmunds and Hale, may vary most widely in strength. As said before, the chemical assay and standardization of some of the most important drugs is impracticable owing to their peculiar constitution. Digitalis is one and ergot is another. Methods of physiological standardization have therefore been adopted for insuring the activity and to a certain extent the uniformity of their preparations. Stewart sums up in favor of drug standardization as follows: "Drug standardization in its large and comprehensive meaning consists in fixing a nomenclature for medicinal drugs, chemicals, and pharmaceutical preparations; in providing methods for insuring uniformity in composition, in physiological action, and therapeutic effect; in adjusting finished products to fixed standards and in devising means for keeping them there for a sufficient length of time to permit their proper application as therapeutic agents; in reducing this knowledge to law and embodying it in system, that we may have a science of materia medica; in embodying this knowledge in text books and teaching it to the medical and pharmaceutical professions, so that it may be used by physicians and pharmacists in the practice of their respective arts. Therefore the importance of drug standardization cannot be overestimated."

---

## PRACTICAL EUGENICS.

Eugenics is scarcely a science, but it is a real point of view. The object of the eugenists is to counteract the degenerating tendency of civilization, but their problem is the securing of an adequate supply of normal human capacity. Their scheme deals with both the positive and the negative, that is, they would encourage reproduction in the specially fit, and discourage it in the unfit. This subject has taken up much space in the public press and has had many interpretations placed upon it. As with all subjects which take hold on the popular mind, it has developed a number of enthusiasts who have made attempts to force premature, extreme views, and cataclysmic suggestions upon the public. The majority of eugenists believe in the control of the mating of individuals, the production of the perfectly normal offspring, and the surrounding of that offspring with the best obtainable environment.

There have been some interesting facts regarding birthrate brought out recently, which may prove of interest in this connection. In the *Practitioner* for April, 1913, Dr. G. T. Young quotes from a paper by Mr. Sidney Webb on the birth-rate in Great Britain in which the author formulated the following conclusions: (1) The decline in birth-rate is greatest in those sections of the population that give proof of thrift and foresight; (2) the decline is principally, if not wholly, due to deliberate restriction in the marriage state; (3) this state of affairs is not due to any alteration of the ages of the population, nor to the number or proportion of the married women, nor to the depopulation of the country districts and consequent centralization in the towns; (4) it is equally definite all over the country, and, in fact, every civilized country with the exception of Russia and Japan, shows the same conditions as England; (5) the condition does not prevail in Jewish and Irish Roman Catholic communities. With two-thirds of the married people, and these the best classes of society, regulating their families, and with no restriction on the increase of the more dependent and ignorant classes, the imagination does not have to make a very great leap to foresee a national problem of huge proportions. Webb thinks that the cure for the condition will be found in the encouragement of "the thrifty prudent parents removing the check

which they put upon their natural instincts." There are here many facts to be digested. The chance is also present for the eugenists to demonstrate that their ideas are practical and not wholly theoretical.

### Pancreogenic Diarrhea.

In 1820 Kuntzmann reported the occurrence of fatty stools in a case of induration of the pancreas. Thirteen years later Richard Bright himself recorded the occurrence of fatty and oily stools which appeared to characterize affections of the pancreas. From then onward the legend increased to the generalized statement that with organic disease of the pancreas the ingested fats pass through the bowel but slightly changed or not at all. This fact became demonstrable at will. Remove the pancreas of a dog and the animal will pass fatty matter. In 1894 Ury and Alexander reported that this fat as it occurs in the stools will solidify outside the body at ordinary temperatures. At a recent session of the Silesian Society for Native Culture, Minkowski made an important announcement (*Berliner klinische Wochenschrift*, April 21). In researches conducted with Abelmann he confirmed the existence of fatty stools in pancreatic defect. But whereas these stools have usually been attributed to absence of lipolytic activity, the author was able to show that the defect was not one of lipolysis, but one of emulsification. The administration of a pancreatic preparation was sufficient to emulsify a considerable portion of the dietetic fat and diminish the fat diarrhea.

### Akin to Fee-Splitting.

Now that the custom of financial dichotomy in medical practice has been acknowledged to be an evil and has been in great measure, though not entirely abolished, it is time to call attention to another "corrupt practice" of like nature. An esteemed correspondent recently enclosed a letter received by him from an instrument maker, a copy of which follows, names being omitted:

New York, April 30, 1913.

Dr. A..... B....., New York,

Dear Doctor:

The business sent by you this month is as follows:

X..... Y....., child's truss.. $5.00

Enclosed please find my check for $1.25. Trusting to be favored with your further patronage, I remain

Very truly yours,

It seems hardly necessary to comment on this letter. If it is reprehensible for the family physician to accept a commission from the surgeon or specialist to whom he has sent a patient, how much more so is it to take pay from a tradesman—druggist or instrument maker—for business thrown in the latter's way.

## News of the Week.

**College of Physicians and Surgeons.**—At the annual commencement exercises of Columbia University, New York, held on June 4, the degree of Doctor of Medicine was conferred by President Butler on one hundred graduates of the College of Physicians and Surgeons. At the same time the honorary degree of Doctor of Laws was conferred by the University on Col. William Crawford Gorgas, assistant surgeon-general of the United States Army and chief sanitary officer of the Isthmian Canal Commission, and on Dr. Alexis Carrel, associate in the Rockefeller Institute for Medical Research and winner of the Nobel Prize for 1912.

**New York University.**—Seventy-five graduates of the University and Bellevue Hospital Medical College received their diplomas as doctors of medicine at the annual exercises held at the University on June 4. The announcement of the award of prizes in the college was made by Dean Le Fevre, as follows: The Valentine Mott bronze medal to Noel H. Campbell of Brooklyn; the John A. Fordyce prize in dermatology to Myron Louis Morris of New York; the Glover C. Arnold prize in surgery in equal parts to Thomas Webster Edgar and Irving Gray, both of New York.

**Medical Schools Graduate.**—At the sixth annual exercises of the Starling-Ohio Medical College of Columbus, Ohio, fifty-three graduates in medicine received degrees. The address to the graduates was delivered by Dr. J. A. Witherspoon, president of the American Medical Association.

The degree of doctor of medicine was also conferred upon twenty-one graduates of the Medical Department of the University of Alabama at the annual exercises in Mobile on May 22. Dean Bondurant announced the award of the Bush Prize to Daniel B. Faust of Clio, and of the Rhett Goode Prize to Frederick F. P. Boswell of Mobile.

**Marquette University Medical School.**—The trustees announce the following additions to the Faculty of the Marquette University School: Professor of chemistry, Dr. Chester J. Farmer of Harvard University; professor of physiology, Dr. J. Vander Erve, for the past three years in charge of the same department of the University of Alabama; professor of biology, Dr. D. V. Sullivan of Western Reserve University. The school will graduate seventy-seven doctors of medicine this year.

**University of Buffalo Medical Alumni.**—The thirty-eighth annual meeting of the Alumni Association of the Medical Department of the University of Buffalo was held in Buffalo on May 27 to 30. The following officers were elected for 1913-14: *President*, Dr. Grover W. Wende, '89, Buffalo; *Vice-Presidents*, Dr. George E. Brewer, '84, New York; Dr. George W. Goler, '89, Rochester; Dr. Frank W. McGuire, '94, Buffalo; Dr. Cynthia W. Koser, '06, Williamsport, Pa., and Dr. Wm. Irving Thornton, '99, Buffalo; *Secretary*, Dr. Julius Richter, '04, Buffalo; *Treasurer*, Dr. Wm. F. Jacobs, '08, Buffalo; *Trustee*, Dr. Henry C. Buswell, '88, Buffalo; *Executive Committee*, Dr. Lesser Kaufman, '04; Dr. Harry Mead, '91, and Dr. Edith R. Hatch, '06.

**Civil Service Examinations.**—The United States Civil Service Commission announces an open competitive examination for both men and women, on July 2, 1913, for the purpose of securing eligibles to fill a vacancy in the position of medical interne in the Government Hospital for the Insane, Washington, at $900 a year and maintenance. As considerable difficulty has been experienced in filling vacancies in the positions of medical interne in the hospital service during the past several years, owing to the limited number of eligibles available, qualified persons are urged to enter this examination. The positions are tenable for one year and applicants must be unmarried, and, of course, graduates of a reputable medical college. Persons desiring to take the examination should

apply at once to the United States Civil Service Commission, Washington, D. C., for Form 1312.

The Commission also announces that the civil service examination for dental interne has been postponed from June 4 to June 18, 1913, because only one application for the examination had been filed by the earlier date. Qualified persons are therefore urged to enter this examination also, which is held for the purpose of securing eligibles from which to fill a vacancy in the position of dental interne in the Government Hospital for the Insane, Washington, at a salary of $600 per annum and maintenance.

**Smallpox in Philadelphia.**—A new outbreak of smallpox in Philadelphia on June 1 caused the vaccination of several hundred persons within the area of one square block. Five cases of smallpox were found on one small street, all the patients being colored.

**Report on "Cures."**—The United States Senate on June 6 unanimously adopted the following resolution which was introduced by Senator Bristow of Kansas: *"Resolved,* That the Secretary of the Treasury be and he is hereby directed, if not incompatible with the public interest, to transmit to the Senate such reports as have been made by officers of the United States Bureau of the Public Health and such documentary information as he may have upon the so-called tuberculosis cures."

**Vivisection Charges.**—Backed by the Society for the Prevention of Cruelty to Animals, several of the most ardent anti-vivisectionists of Philadelphia have brought charges of cruel and inhumane treatment against the research workers in the medical department of the University of Pennsylvania, and on June 3 Dr. J. E. Sweet, assistant professor of experimental surgery was served with a warrant calling for his appearance in court. At the hearing before a magistrate on June 7 Professor Sweet was held in $400 bail for trial. The complaining witnesses produced a "gibbet of torture" said to be an exact duplicate of apparatus in use in the laboratories during operations upon dogs, and one of the witnesses stated that once a week for the last six months she had crawled through a hole in the fence surrounding the animal house so as to inspect the condition of the dogs there confined.

**City Death Rate.**—The death rate in New York City during the week ending May 7, was 12.85 per thousand, representing a total of 1,323 deaths, as compared with a rate of 12.86 and a total of 1,275 deaths during the corresponding week of last year. There was an increase of fifty-one in the deaths of persons of sixty-five years and over, and the mortality from measles, diphtheria, and whooping-cough was also much increased. There was an increase also in the deaths due to organic heart disease, pulmonary tuberculosis, and kidney disease, while scarlet fever, typhoid fever, and the diarrheal diseases showed decreased mortalities.

**Milk Stations Opened.**—Ten additional stations for the distribution of pasteurized milk during the coming summer were opened by Mr. Nathan Straus on June 2 in New York City. At these stations whole milk, which has been properly pasteurized, is supplied at one cent a glass, while for the babies milk modified according to various formulæ is also supplied.

**Rockefeller Institute.**—The governing boards of the Rockefeller Institute for Medical Research, New York, have, through the generosity of Mr. Rockefeller, been able to provide pensions for the members and associate members of the Institute. The rules adopted permit of the allowance of pensions amounting to three-fourths of the salary to members of the Institute retiring at the age of sixty-five after fifteen years or more of service, and of pensions amounting to one-half to three-quarters of full pay according to length of service to members and associate members retiring at sixty years. There is also a provision for total disability after ten years of service and for widows and orphaned children. Mr. Rockefeller's gift securing the pensions is said to amount to about one-half million of dollars.

**To Enlarge Mount Sinai.**—The trustees of Mount Sinai Hospital have purchased the property numbered 21 and 23 East 99th street, and have thus almost completed their control of the block bounded by Fifth and Madison avenues and by 99th and 100th streets. On this plot the hospital will erect the new buildings which have been planned, including the children's wards and the pathological laboratory.

**American Medico-Psychological Association.**—The sixty-ninth annual meeting was held at the Clifton Hotel, Niagara Falls, Canada, on June 10 to 13, 1913, under the presidency of Dr. James T. Searcy of Tuscaloosa, Ala.

**Public Health Board.**—Under the auspices of the Public Health Committee of the New York Acadamy of Medicine, representatives of nearly one hundred private charitable organizations, met at the academy on June 4 and formed a central committee for the purpose of securing co-operative effort toward the general conservation of the public health in this city. The aim of the conference was shown in the adoption of the following resolution:

*Whereas,* There are in the city about 100 private organizations interested in the various phases of public health work; and

*Whereas,* The existing lack of close co-operation and co-ordination permits duplication and waste of effort as well as distinct loss in effectiveness of the various independent endeavors; therefore be it

*Resolved,* That a central committee on the public health of New York City, composed of representatives of the various organizations, be chosen to act as a clearing house for the exchange of ideas and information, and for the co-ordination of the varied private health activities of the city and to provide for the institution of an annual conference of the organizations.

The Central Committee is made up as follows: John H. Finley, president of City College, *Chairman;* Dr. E. H. Lewinski-Corwin, *Secretary;* Dr. John H. Huddleston, Miss Lillian D. Wald of the Nurses' Settlement; Dr. Edward L. Keyes, Jr., Director of the Society of Moral and Sanitary Prophylaxis; Dr. C. E. A. Winslow of the American Museum of Natural History, Dr. Luther H. Gulick of the Parks and Playgrounds Association, Dr. Livingston Farrand, Homer Folks, and Dr. Charles L. Dana, chairman of the Public Health Committee of the Academy of Medicine. It was announced that Mrs. E. H. Harriman had offered to meet the expenses of carrying on this work.

**Personals.**—Dr. Simon Baruch, professor of hydrotherapy in the College of Physicians and Surgeons, New York, has presented his resignation to the trustees of Columbia University, and this has been accepted.

The resignation of Dr. Augustus B. Wadsworth, assistant professor of bacteriology in the College of Physicians and Surgeons has also been presented and accepted.

Dr. Raymond F. C. Kieb, first assistant physician at Dannemora Prison, New York, has been appointed superintendent of the Matteawan State Hospital, New York.

**Gifts to Charities.**—By the will of the late Rev. Charles M. Morton, formerly of Philadelphia but recently of Atlantic City, the sum of $5,000 each is bequeathed to the Pennsylvania Hospital, the Children's Seashore House at Atlantic City, and the Mercer Memorial Home for Invalids at Atlantic City, and the sum of $3,000 to the Philadelphia Home for Incurables.

By the will of the late Henry B. Palethorp of Philadelphia, the sum of $5,000 each is bequeathed to the Jewish Hospital, the Wills Eye Hospital, the Pennsylvania Hospital, and the Presbyterian Hospital of Philadelphia.

The Middlesex Hospital of London has received from Mr. Arthur James a gift of $100,000, the income of which is to be used in the research work on cancer conducted by the hospital. The gift is made in memory of Mr. William James.

**Illinois State Medical Association.**—At the annual meeting of this society held at Peoria, the following officers were elected: *President-elect,* Dr. A. L. Britton, Athens; *Vice-Presidents,* Dr. Sumner M. Milner, Peoria; and Dr. Domer G. Smith, Elizabeth; *Secretary,* Dr. W. H. Gilmore, Mount Vernon; *Treasurer,* Dr. A. J. Markley, Belvidere. The next meeting will be held at Decatur.

**Connecticut State Medical Society.**—The following officers were elected at the annual convention, held at Hartford on May 22: *President,* Dr. David Chester Brown, Danbury; *Vice-Presidents,* Dr. William S. Hulbert, Winsted, and Dr. Kate C. H. Mead, Middletown; *Secretary,* Dr. M. M. Scarbrough, New Haven; *Treasurer,* Dr. J. H. Townsend, New Haven.

**West Virginia State Medical Association.**—Officers were elected at the annual meeting at Charleston on May 23, as follows: *President,* Dr. Richard E. Venning, Charlestown; *Vice-Presidents,* Dr. C. M. Scott, Bluefield; Dr. Frank B. Murphy, Philippi, and Dr. James E. Cooper, Cameron; *Secretary,* A. P. Butt, Davis; *Treasurer,* Dr. H. G. Nicholson, Charleston.

**New Hampshire Medical Society.**—At the annual meeting of this association held at Concord on May 13, officers for the ensuing year were elected as follows: *President,* Dr. Abram W. Mitchell; *Vice-President,* Dr. H. K. Faulkner, Keene; *Treasurer,* Dr. Charles R. Walker, Concord.

**Montana State Medical Association.**—The annual convention at Great Falls closed on May 15 with the election of the following officers: *President,* Dr. W. P. Mills, Missoula; *Vice-Presidents,* Dr. James H. Irwin, Great Falls; Dr. E. G. Balsam, Billings, and Dr. Sidney A. Cooney, Helena; *Secretary,* Dr. Herbert D. Kistler, Butte; *Treasurer,* Dr. C. C. Wallin, Lewistown.

**Obituary Notes.**—Major Robert Lauder, M.D., surgeon in charge of Fitch's Home for Soldiers at Noroton, Conn., a graduate of Yale University, Medical Department, in 1871, a veteran of the Civil War, and a member of the Connecticut State and Fairfield County Medical Societies, died at his home from disease of the kidneys after a short illness on May 31, aged 72 years.

Dr. Jackson W. Jones of East Chattanooga, Tenn., a graduate of the Louisville Medical College, Ky., in 1886, died at his home on May 21, from cerebral hemorrhage, aged 58 years.

Dr. Alfred Morton Allen of Wilmington, Mass., died at his home on May 22, aged 59 years.

Dr. John Augustine Magee of Lawrence, Mass., a graduate of the University of Vermont, College of Medicine, Burlington, in 1872, and a member of the State Board of Health, and of the Massachusetts State and Essex North District Medical Societies, died at his home suddenly on May 23, aged 65 years.

Dr. Morris Drossner of Jersey City, N. J., a graduate of the University of Greifswald, Germany, in 1863, died recently at his home, aged 70 years.

Dr. Franklin Benjamin Gottschalk of Chicago, Ill., a graduate of the Northwestern University Medical School, Chicago, in 1894, and a member of the Illinois State and Cook County Medical Societies and of the North Side Physicians' Club, died at his home from blood poisoning following an accident, on May 22, aged 45 years.

Dr. Hugh Baker of Connellsville, Penn., a graduate of the University of Pennsylvania, Department of Medicine, in 1901, and a member of the American Medical Association and of the Pennsylvania State and Fayette County Medical Societies, died in Wilmington, Del., from blood poisoning, on May 29, aged 45 years.

Dr. J. Boyd Risk of Summit, N. J., a graduate of the University of Pennsylvania, Department of Medicine, in 1879, and a member of the American Medical Association and of the New Jersey State and Union County Medical Societies, died at his home on May 30, aged 56 years.

Dr. Walter C. Gilday of New York, a graduate of the Albany Medical College in 1894, and a member of the New York Academy of Medicine, the New York State and County Medical Societies, the Clinical Society of the New York Polyclinic, and the Celtic Medical Society, surgeon to St. Elizabeth's Hospital, and assistant surgeon to the New York Polyclinic Hospital, died at his home, from acute gastritis following ptomaine poisoning, on May 31, aged 42 years.

Dr. Ellmore S. Allbee of Bellows Falls, Vt., a graduate of the Albany Medical College in 1870, a member of the American Medical Association, the Vermont State and Windham County Medical Societies, and the Connecticut River Valley Medical Association, and for more than twenty years health officer of the Town of Rockingham, died at his home from pneumonia, after a short illness, aged 65 years.

Dr. Matthew John Leland of Brooklyn, N. Y., a graduate of the New York University Medical College in 1883, and a member of the American Medical Association, the New York State and Kings County Medical Society, and the Brooklyn Neurological Society, died at his home on May 29.

Assistant Surgeon Frank W. Thompson, United States Navy, a graduate of the Medical Department of Yale University in 1907, and a member of the American Medical Association, died at the Naval Hospital, Newport, R. I., from pneumonia, on May 30, aged 30 years.

Dr. John Pitman of Kirkwood, Mo., a graduate of Washington University, Medical Department, in 1864, a member of the American Medical Association, and of the Missouri State and St. Louis County Medical Societies, and for many years

a member of the Kirkwood Board of Education, died in St. Luke's Hospital, St. Louis, from peritonitis following an operation for appendicitis, on May 28, aged 76 years.

Dr. Allan Mott Ring of Arlington, Heights, Mass., a graduate of the New York University Medical College in 1867, and a member of the American Medical Association, and the Massachusetts State and Middlesex County Medical Societies, died at his home on June 3, aged 68 years.

Dr. John W. Shockey of Columbus, Ohio, a graduate of the Physio-Medical Institute, Cincinnati, in 1874, died at his home on May 26, aged 68 years.

## Correspondence.

### OUR LONDON LETTER.

(From Our Regular Correspondent.)

INSURANCE COMMITTEE—ALIMENTARY TOXEMIA—DRUGS, OLD AND NEW—HOSPITAL SATURDAY FUND—LECTURES—NOTES.

London, May 23, 1913.

Yesterday the insurance committee for London declared it was undesirable for any panel doctor to undertake more than 2,000 insured persons on his list. The chairman, Mr. Dawes, M.P., said that about 930,000 persons had selected their doctors by April 14. A subcommittte had recommended that a surplus sum should be distributed in respect of about 400,000 persons who on April 14 had not selected their doctors. The question was put what authority the committee had to allocate the money? It was answered that a circular of the Insurance Commissioners recommended it. To this it was naturally objected: "We are bound by the Act and regulations and not by a circular." The chairman evidently felt the force of this and said it was a legal point which he could not decide, and he withdrew the proposal, for if payments were made by the committee without justification their position would be difficult. Mr. Rockliff, who proposed the limitation of the doctors' lists to 2,000 insured patients, said an average of 1,149 had been taken and one man had double that number and fixed his hours for panel persons at three on week days and one on Sundays, and so three minutes and a fraction were available for each for whom he prescribed. Dr. Lauriston Shaw thought the warning already given would prevent medical men taking more than they could adequately treat. To fix the number would be contrary to the principle of the Act and interfere with the free choice of doctor. Mr. Wood declared there were many cases which would not get proper attention because the number on the doctor's list was too great. Dr. Evan Jones held that 2,000 was the maximum anyone should have to treat. Sir S. Murphy suggested it would be better to wait until the panel was joined by more doctors before deciding on the matter, but the resolution was adopted by a majority.

The special discussion on "Alimentary Toxemia" has at length been closed. The several adjournments and the numerous speakers who took part in the discussion—not less than sixty—have kept the subject before the profession so long and opened so many side views that it will probably be talked of for a good while to come. Indeed it is now apt to intrude into any casual chat between doctors, though most of them admit they have only been interested in some one or two points. There are those who think these long drawn out debates are rather wearisome functions and the communications more adapted for perusal at leisure than for listening to. Certainly there is a lack of spontaneity when so many speeches (so-called) bear marks of elaborate preparation. Others maintain that it is in such set debates that we are most likely to secure the ripe views of busy men whose large experience is most valuable. Both opinions may easily be defended, and perhaps formal debates on this scale may establish a special claim on our attendance.

To the notes I sent you about the meetings in March and April I must add a few lines on those in the present month to finish it, though each one was worthy of a lengthy description. The products of bacteria were regarded by some as all of them toxic, but others were more than doubtful of this Sir J. Goodhart remarked that the colon had a function and though it had been spoken of as only absorbing moisture, its great surface exposed to the food was for something, and it should be kept full, not empty. Dr. Somerville showed the evils of excessive consumption of proteins, and said it was not what happened in the alimentary canal that mattered so much as what was always going on in the tissues. Dr. Jordan showed a number of skiagrams to prove that kinks in the ileum were seen only in patients with distended duodenum and evidence of toxemia. Dr. Langmead dealt with the thyroid in relation to tetany, goiter, arthritis, etc., and mentioned he had used a vaccine of coliform bacilli. Others traced to intestinal toxemia an array of diseases in the skin, the eye, and various tissues and organs; in fact, most of the "ills that flesh is heir to." But caution was commended by equal authorities.

Dr. Rolleston had a good deal to say about toxemia of intestinal origin, but he admitted too much might be made of it and some of the defects attributed to it might be due to small numbers of organisms passing via the blood to the tissues, as in Adami's subinfection with *B. coli*. The relationship with the digestive processes of many of the disorders that had been discussed had been recognized for a long time. Indiscretions in diet were considered causes of arterial and renal diseases; lately it had been said the suprarenals enlarged in arteriosclerosis. Arthritis in several aspects seemed closely connected with digestion; in acute rheumatism the synovitis was transient and the evidence of toxins accordingly difficult to establish in chronic rheumatoid there might be a focal infection. Thyroid insufficiency might also be induced by autotoxemia and on depression of its secretion blood pressure would rise and arteriosclerosis follow as a consequence.

Dr. D. Wilson said he had had 800 cases at Harrogate which he attributed to toxins absorbed from the colon. They were nearly all treated by irrigations of the mineral water and the other methods of the Spa. Dr. Brook had been accustomed to examine the feces in neurasthenia, and in fifty-four fully detailed cases found the flora abnormal. He used antogenous vaccines (minute doses at first). Of intestinal antiseptics only beta-naphthol and sulphur were of use. Dr. Armstrong said dental sepsis would set up joint mischief, but this tendency had been overrated. Dr. Sibley found various skin affections brought about by toxins. Dr. McCulloch said microbes were most prolific in lymphatic channels and it was the lymph which most needed protection from them. Dr. Briscoe said that in 2,000

p. m.'s in a lunatic asylum, Dr. Mott had not found one with signs of appendicitis, and mentioned other facts showing that serious intestinal disease is rare. Dr. Vincent discussed the biochemical processes going on in the alimentary canal of the healthy infant and contrasted them with the conditions found in intestinal toxemia.

The Gresham lectureship has often been spoken of slightingly, but as it is endowed there seems no reason why it should not give rise to meritorious contributions.

The professor of medicine this year certainly succeeded in interesting a goodly number of people by peeping into early knowledge, his subject being "Drugs, New and Old." He opened by remarking that as man became civilized he perpetuated his knowledge on tombs and other ancient writings from which we learn that castor oil was employed by the ancient Egyptians, about 5,000 years ago; rhubarb by the Chinese long before the Christian era, saffron in remote ages, while opium was well known to the Roman and Greek authors. The knowledge of drugs at present was partly empirical, though chemical qualities may be of service in fixing the uses of some. Many have reached us from uncivilized people, *e. g.* quinine. Botanical gardens cultivated medicinal plants in the seventeenth and eighteenth centuries in European cities and universities. The Apothecaries' Garden at Chelsea, the gift of Sir Hans Sloane in 1686, was noted for its herbs. Animal products were used as remedies from very early times, and faith in them survives in some savage races. The Malays ate tigers' flesh to increase strength and cunning. More civilized people were led by such notions to try most revolting substances, such as fox's lung for cough, a live spider rolled in butter to make a pill for jaundice. Vipers cooked in various ways and salted or powdered were held in the highest esteem. Belief in unicorn's horn is traceable to early time, and much so named (perhaps tusk of a whale) was sold. It was said that a King of France had one valued at £20,000. Most remarkable was the belief in parts of the human body for medicine. Hair, blood, etc.; nothing was too revolting. Most valued were skulls of those who died violent deaths. The head of a hanged criminal would sell from 8 to 11 shillings if moss had grown on it—to make of this a sympathetic ointment as infallible against epilepsy in the seventeenth century. The four physicians of Charles II prescribed twenty-five drops of spirit of human when he was attacked with apoplexy. In the seventeenth century there arose a profound belief in powdered mummy as an internal medicine, but the sceptical denounced it as fraud, showing that more mummies were prescribed than came out of Egypt. The lecturer mentioned some notes from Gerarde, who tended the garden of Lord Burleigh (which was in the Strand), and who had a garden of his own in Holborn, then described as "in the suburbs of London." Gerarde will be well known to your readers interested in old herbal lore, so I will only make one citation. Of Solomon's seal he said: "The root stamped while it is fresh and greene and applied taketh away in one night, or two at most, any bruise, black or blewe spots gotten by falls or women's wilfulnesse in stumbling upon their husbands' fists, or such like." The patient of old, like many today, seemed to like a smack of mystery about his medicine, and the lecturer said the ancient practitioner seemed willing to play up to this weakness. Today it is estimated quack medicines in England are sold to the extent of above £2,000,000 a year, enough to keep up 40,000 hospital beds. This waste of money, mostly by those who can ill afford it, would be bad if only waste, but much is not harmless, but very injurious. Herbals became less important when the study of drugs led to their supersession by pharmacopœias—the first of which issued under authority, being that of Mürenburg (1542).

A meeting of the Hospital Saturday Fund has been considering a flood of complaints against hospitals by insured persons under the new Act. It was found they had not chosen their doctors and had no knowledge that their ordinary ailments would in future have to be treated by practitioners on the panel. It was found that these complaints began suddenly in January, but ceased almost entirely by February 1, bringing the number below the average for that date. It was reported that all complaints had been referred to the hospitals concerned and had been fully investigated, and wherever possible all hospitals had done their utmost to meet suggestions or wishes expressed by the Fund.

The Fitzpatrick lectures were given this year by Dr. Raymond Crawford on "Echoes of Pestilence in Literature and Art." He mentioned that Lucretius seemed to explain the outbreaks on a kind of atomic theory, Varro attributed them to living microbes, and others had associated them with comets, earthquakes, and meteorological phenomena.

The Horace Dobell lecture was given by Dr. C. J. Martin, doctor of the Lister Institute, on "Insect Porters of Bacterial Infection."

An appendix to the report of the Royal Commission on tuberculosis was issued on Monday, in which full details of the experiments are given and a number of charts depicting the results of tuberculin tests on different animals.

A donation of £10,000 has been given by Mr. Tate to the Cancer Research Fund.

Princess Christian on Monday laid the foundation stone of an extension of the Royal Free Hospital, which is estimated to cost £40,000.

## OUR PARIS LETTER.

(From Our Regular Correspondent.)

EXAMINATION OF THE BLADDER IN CASES OF CANCER OF THE CERVIX UTERI—PATHOGENESIS AND TREATMENT OF GOUT—THE STARVATION TREATMENT OF GUELPA—AMBARD'S METHOD OF DETERMINING FUNCTIONAL RENAL INSUFFICIENCY—TECHNIQUE OF THIS METHOD—ITS VALUE.

May 1, 1913.

THE examination of the bladder in cases of cancer of the cervix uteri was the subject of a paper read before the Surgical Society by Pierre Gruet. This observer has studied the bladder in women affected with uterine cancer in order to determine whether this organ gave any information that would be of value from the operative viewpoint. Cystoscopy indeed yielded very interesting results. One of the first changes in the bladder during the course of uterine cancer is the bulging forward of the bladder wall in front of the neoplasm. If the bulging is limited to the region of the trigone, the ureteral orifices are displaced upon the lateral and superior aspects of the arch. At the same time there are important circulatory changes. In some cases there is an increased prominence of the blood-vessels and a multiplication of the latter, owing to the

fact that the faint vascular arborizations become more visible. In other cases when the lesion is more advanced one may detect the presence of elongated transverse folds. These folds are more frequent behind the interureteral muscle. Sometimes there is an edema which may be diffuse, raising the vesical mucosa en masse, and giving it the appearance of a cushion. In other cases the edema forms large parallel folds which infiltrate the bladder. At times one may note a bullous form of edema composed of clear vesicles of various dimensions, from that of a pinhead to that of a grape. Among these may be frequently noted small, irregular, reddish ulcerations covered with a false membrane. In some cases finally there is an invasion of the bladder mucosa directly by the cancer. At first this appears in small, smooth, whitish granulations, embedded in the mucosa, and pinhead in size. Later there appear nuclei the size of a small pea whose capacity and hardness differentiate them from the edematous swellings. At last the cancerous invasion causes an ulceration and perforation of the bladder wall.

Cystoscopic examination enables one to draw conclusions with reference to the question of operability. In fact, the detection of carcinomatous invasion of the vesical mucosa contraindicates any radical operation. The simple bulging of the floor of the bladder has no importance from the operative viewpoint. It is necessary to bear in mind, with reference to the operative indication, the condition of the ureteral orifices. These may be entirely surrounded, compressed, or invaded by the neoplasm. Moreover, the study of the ureteral outflow is even more important. One may detect a delay in the outflow, which may finally come with greater impetus, or there may be an irregularity in the outflow, and at times there may be spasms of the ureteral orifice without any real ejaculations of urine. The determination of these facts is important for they suggest interruptions in the permeability of the ureter or its possible cancerous invasion.

The pathogenesis and treatment of gout was discussed at a recent meeting of the Academy of Medicine. An extensive study of this subject was made by Guelpa. According to this observer the uric acid which is found in gouty individuals in a state of saturation is not in such excess because of an excess in its production, but because on the contrary the dietetic abuses have modified the blood in which the uric acid was present normally in a soluble state. Dietetic excess, particularly an excessive alkalinity and superabundance of mineral constituents causes a precipitation in the blood of uric acid and various salts, particularly the phosphates and the oxalates. Hence results deposition of the tophi which are the tangible and characteristic evidence of gout.

In the treatment of this condition Guelpa recommends the absolute prohibition of food for three or four days, accompanied by the administration each day of a strong purgative which will ensure a watery evacuation. Following this there is given a restricted diet, consisting mainly of meat, while milk and vegetables are avoided. This method of feeding frequently causes acute crises of gout, which are temporarily necessary for the progressive diminution in the size of the tophi. At the same time it is a good plan to add to the diet sweetened beverages which are very useful in calming the painful crises, and in sustaining muscular power.

An interesting discussion followed the reading of the above communication. Bouloumie thought that most of the cases reported by Guelpa were in reality instances of chronic rheumatism and not of gout. Salignat believed that the starving treatment was too exacting for certain individuals. Many gouty individuals are too weak to stand this form of treatment, which would, moreover, make them more susceptible to intercurrent affections, particularly tuberculosis.

Ambard's method of determining renal insufficiency was the subject of a paper read before the Medical Society of Paris by Carrion and Guillaumin. Ambard's method constitutes a new and important step in advance, in its comparison of the simultaneous content of urea in the blood and urine. Ambard has shown that in the healthy subject there is at all times a definite ratio between the urea in the blood and the urea in the urine. This ratio being unchangeable is expressed by a constant figure called the "constant of Ambard." Even in the case of renal disease this ratio is similarly a constant one, from one moment to another, but it has another value and is expressed by another figure than in the healthy individual. Hence side by side with the normal constant there are the pathological constants, which vary from the normal one in direct proportion to the extent of disease in the kidney. Ambard's constant, therefore, furnishes a criterion of diagnostic, prognostic and therapeutic value in the management of renal disorders. Ambard's constant is arrived at by arithmetic. In an individual of known weight the urine excreted in a short period is measured. There is then calculated (1) the urea content in the urine, (2) the rapidity in the excretion of urea, and (3) the content of urea in the blood. If the experiment is tried a number of successive times the same day or on different days, one will obtain different results, for the content in urea varies according to the diet. The urinary content in urea varies according to the abundance of fluid taken, but in this Ambard discovered the law according to which the kidneys maintain the reciprocal relationship between the blood and the urine. This law is expressed by the mathematical constant for the normal man, namely, 0.070. If the secretory function of the kidney is insufficient, this constant rises. Therefore the tendency to uremia is proportionate to the size of the constant. The great interest that attaches to this method depends upon the fact that the content of urea can be determined in a manner at once practical and precise.

The technique of this method is as follows: There are obtained 10 cubic centimeters of blood, which is defibrinated and poured into a conical vessel. There is then added little by little and at the same time triturated with the blood by means of the bottom of a test tube, an exactly equal volume of a 20 per cent. solution of acetic acid, and the mixture is then filtered. There are then taken ten cubic centimeters of the filtrate which are placed in the ureometer. There are then added three or four cubic centimeters of caustic soda diluted with two volumes of water. There is next added a certain amount of water and then the hypobromite of sodium. The reading is made in the usual manner.

The subject on whom the determination is being made should take, one-half hour before the experiment, a half liter of water in order to increase the amount of urine secreted. The urine is then completely voided from the bladder, and a minute later the specimen of blood is obtained by means of wet cupping, a venous puncture, or a venesection. It is necessary to collect twenty cubic centimeters of blood. In about twenty minutes the subject empties

his bladder for a second time, the urine is collected, and it is upon this specimen that the calculation is made. The weight of the subject should be determined, for this enters into the calculation.

The results obtained by "Ambard's constant" are quite interesting. Whatever may be the content of urea in the blood, whatever may be the diet, whatever may be the day or the hour of the experiment, the "constant of Ambard" shows whether the kidney is impaired or not, and if impaired, even to a slight extent, it shows the exact degree of this impairment. No other method is as suitable or as certain.

7. Tuberculous Osteomyelitis of the Digits. R. M. Green.

1. **Protection of Milk.**—E. M. Buckingham states that the production of a good and safe milk is not a hopeless problem. Milk production should be guarded by an efficient official inspection. Pasteurization is efficient, but it, too, has its dangers and should also be guarded by an efficient official inspection. There is some evidence that pasteurization is injurious to young children and that for the present a safe raw milk is to be preferred for them.

2. **Control of the Careless Consumptive.**—M. W. Richardson believes that health boards have support in law for much more drastic action as regards the careless and incorrigible consumptive than has been supposed, and that such legal support can be invoked with success, especially by those communities which are provided with isolation hospitals for consumptives.

3. **Efficient Boards of Health.**—R. N. Hoyt finds that the chief difficulty in the way of cooperative health work is political jealousy. This obstacle is avoided by a plan now being developed by Professors Sedgwick and Phelps of the Massachusetts Institute of Technology, who have organized a staff of trained men prepared to give efficient health protection to any group of towns at actual cost. Being under the wing of an educational institution, the organization is freed from political or commercial affiliations. This plan is already in operation in a group of towns about Boston, comprising Wellesley, Framingham, Needham, Weston, and Belmont. Other towns have accepted part of the service. The organization consists, first, of a board of advisory experts, consisting of professors in the department of biology and public health. Each member is a recognized expert in some line of public health work and stands ready to give his advice and assistance when needed. Second, there is a working staff of trained men consisting of a health officer, a bacteriologist, and chemist and a plumbing and sanitary inspector. These men, with their assistants, plan to care for a circle of towns from a central office and laboratory. An automobile and motorcycle and the telephone furnish quick communication with all parts of the district served. It is expected that similar organizations will shortly be brought together from other districts. This technology plan of expert public health work for small communities marks an important step in the direction of progress. When it shall have been fully developed by careful trial and study and has been made to conform to practical working conditions, it will undoubtedly mark a distinct advance in modern sanitary science.

7. **Tuberculous Dactylitis.**—R. M. Green concludes that tuberculosis osteomyelitis of the digits is essentially a disease of infancy and childhood presenting a definite clinical picture and tending strongly to spontaneous recovery. Pathologically it is characterized by bone destruction and rarefaction and by chronic inflammatory reaction in the surrounding soft tissues. It may heal by resolution and absorption, or by sequestration, suppuration, and sinus formation. Its differential diagnosis from pyogenic osteomyelitis, sarcoma, and syphilitic dactylitis may be made by clinical signs and *x*-ray examination. Its prognosis for anatomical and functional recovery is good and is proportionate to the amount of bone destruction and scar-formation. Therapeutically primary emphasis is to be laid upon general hygiene and local fixation. Incision should rarely be resorted to, since it complicates the dressing, protracts convalescence, and increases subsequent deformity and disability. Amputation is almost never indicated. Probably treatment with the *x*-rays, or other forms of irradiation, is a valuable adjunct to the conservative therapeutic measures above described, since it expedites recovery by stimulating natural reparative processes.

12. The Successful Treatment of Atrophic Rhinitis and Ozena; A New Remedy. L. Jacobs.

2. **Care of Tuberculous Employees.**—A. H. Doty believes that the most practical and economical means of securing additional accommodations for the isolation and care of tuberculous patients would be to allow individual companies or corporations to erect and equip on the grounds of the State or municipal sanatoria, cottages or small buildings capable of holding eight or ten patients, similar in construction and appearance to those already in use, or modified as the State or municipal authorities might direct, and solely for the care of employees of such individuals, companies, or corporations; provided that the employees are also residents of the municipality or State supporting the sanatorium in question, and therefore equally eligible with others for admission whenever a vacancy should occur. The advantage secured under this plan consists in the certainty with which the beneficiaries may promptly enter the sanatorium, without remaining indefinitely on the waiting list. Furthermore, this in no way interferes with the admission of others who are applicants for care and treatment in the said institution through the ordinary channels. Neither the individual nor the company constructing these buildings, nor the employees occupying them, should be entitled to receive any additional privileges, or a voice in the management of the institution. The patients sent in by the company would be under the same discipline and jurisdiction as those entering in the ordinary way. It would simply mean that those who were selected for treatment in the companies' buildings would secure prompt admission.

8. **The Treatment of Syphilis.**—M. B. Parounagian outlines as follows his method of treating a fresh case of syphilis in an adult: After demonstrating the spirochetes one should excise if possible the primary sore, particularly before the eruptive stage, as this would remove an important focus of spirochetes. If the excision is not prac-

ticable, inunctions of calomel ointment, thirty-three per cent., should be applied to the chancre. Injection (intravenous) of three or four doses of salvarsan should be given, if possible in rapid succession, and then, notwithstanding the absence of clinical symptoms and a possible negative Wassermann reaction, the patient should be subjected to a vigorous course of mercury, perhaps corresponding to one-half the amount and time which would have been devoted to this form of treatment had salvarsan not been given at all. For those having the advantages of large clinical and hospital facilities, and who can follow their patients for years, the treatment with salvarsan alone may suffice; but by the average general practitioner, who sees patients in a more transient way, the combination treatment should be used. That is, the patients should be given the chance of cure which salvarsan holds out, but should not be denied the benefits which we know follow the use of mercury. Moreover, if for any reason it were incumbent upon the practitioner to choose between the two remedies—in the light of the experimental stage of salvarsan at the present day, and in justice to the time-honored remedy, which has survived for four centuries—the author believes mercury should be given the choice, at least for the present.

11. **Acute Intestinal Obstruction.**—R. A. Barr emphasizes the following points: Digestive disturbances, with colic, following abdominal operations, should be treated with opiates and not with purgatives. A suspected mechanical obstruction should never be treated or tested by purgatives by the mouth. Under such circumstances the painful peristalsis should be quieted with opiates. Attempts to move the bowel should be made only with enemata. Patients with suspected strangulation of the bowel, or with mechanical obstruction of any type that does not yield promptly to opiates, gastric lavage, purgative enemata, and hypodermoclysis should be treated by section. In all patients, except desperate cases that are operated on a search should be made for the obstruction, provided no adhesions are present. This search should, if possible, start with the cecum, and should proceed up or down the gut, as determined by the flaccid or distended state of the cecum. If the obstruction is not located after a brief search, enterostomy should be done at the lowest point in the distended gut that is practicable. This should be made by fastening in a rubber tube with sutures, after the manner of a Kader or Senn gastrostomy. There is one technical point that the author presents. It concerns a plan he has used only once. When resection is done for damaged gut, and anastomosis is considered justifiable, one should use the lateral suture method, and establish gut drainage by fixing the proximal end of the gut in the operating wound, or in a stab wound, after fixing a tube in it by two or three successive purse strings of catgut. By this means the proximal bowel is given an outlet for its accumulations, and the suture is absolutely relieved from stress and strain due to distention of the gut. Spontaneous closure of the fistula is practically assured, since a portion of it is lined with peritoneum.

12. **Treatment of Atrophic Rhinitis and Ozena.**—L. Jacobs presents the following conclusions: The substance known as scarlet red may be applied to the nasal mucous membrane without producing any constitutional symptoms. The best excipient for this application is mucilage of acacia. Lasting results of great benefit in atrophic rhinitis may be obtained by the use of this remedy. The treatment is simple and of short duration.

2. **Fuchsin in the Treatment of Chronic Leg Ulcer.**—E. S. May and M. L. Heidingsfeld treated twenty selected cases of chronic leg ulcer with an ointment made up as follows: Fuchsin (Grübler's) 5 parts; eucalyptus oil, 10 parts; anhydrous wool fat, 100 parts. The results were remarkably good. The ulcerations cleaned rapidly and pus and all evidences of secondary inflammation disappeared promptly with relief of pain. In a few cases, however, the use of the remedy over a period of several weeks caused a mild inflammatory reaction and dermatitis, and the formula was changed to the following: Fuchsin (Grübler's), 1 part; petrolatum, 5 parts; anhydrous wool fat, 100 parts. This has been well borne in all cases. The authors insist on the importance of the character of the fuchsin employed and believe that in this class of cases basic fuchsin possesses the most satisfactory therapeutic efficiency.

3. **Treatment of Nephritis.**—M. H. Fischer summarizes his method of treatment as follows: One should give alkalies, salts and water—the alkalies to neutralize the abnormal acid in the kidney and elsewhere, the salts because the various changes induced in the kidney colloids by acids are counteracted by adding any salt, even a neutral one, and the water is given in order to have more of it present in the body than is necessary to saturate all the body colloids, otherwise we would have no "free" water for the secretion of urine. In most cases after attacking the toxic and other causal factors, removing them as far as possible and attempting to render the others innocuous, one should attempt to reduce the concentration of the acid by giving water systematically, and a good way is to give a glass every hour, day and night. If it contains an alkali, so much the better; but the dietary can be made an excellent vehicle for introducing alkalies and salts into the body, and the author would not restrict the amount of table-salt used. If the gastric route is not sufficient the rectal can also be employed to introduce the remedies. In severe cases the best and quickest method is to inject something into the blood. The author finds that one of the same formulas given for the rectal method (sodium carbonate, 10 grams, and sodium chloride, 14 grams, in 1,000 c.c. of water) does very well if injected directly into the vein in case of suppression or convulsions, persistent vomiting, etc.; from 1,800 to 2,000 c.c. of the solution should be given for the first dose and proportionately less for a child. If this fails he gives a second injection still larger at a period of from six to twelve or twenty-four hours after the first, the injections to be given as slowly as conveniently possible. The author mentions that some reactions that may follow cannot always be avoided and that the patient should be protected and guarded against chills. When the condition has advanced to one not of pure nephritis but one complicated with failing heart, alkalies and salts cannot supply the needs if the heart has dropped to its lowest level of efficiency and has lost its recuperative powers.

6. **Radium Treatment of Superficial New Growths.**—F. H. Williams and S. W. Ellsworth note that the application of pure radium bromide in sufficient amount, properly used, is a harmless, painless, and efficient method of treating early superficial new growths. Radium is well adapted to cancers of the face, as the cosmetic results are excellent, and particularly to the eyelids, where operation may offer special difficulties and disadvantages. With

proper care there is no danger to the eye. Operation is still considered to-day the method of choice in early skin cancers by most practitioners, but the results obtained here and abroad show that radium should be used first in early cases and operation reserved for such as are not readily controlled by it. Radium is more successful when it is the first treatment employed than when it is used after operation, *x*-rays, or other forms of treatment, although even under these circumstances it does well. The number of treatments required in some cases is from two or three to ten, while in others more than twenty are needed. Improvement usually takes place after two or three applications of the radium. Many people dread the knife, even for a simple operation, and fearing surgical interference will be advised, delay coming for treatment, thus lessening the chances of recovery. Radium is free from dread, as its action is painless. The analgesic action of radium is noteworthy. For keloids, unless extensive, radium is by far the best treatment known to us. Where radium is obtainable, it would be well to use it for skin lesions of small area which do not heal readily under simple applications. All powerful remedies have dangers, but they can be avoided if care is taken. During the seventeen years the *x*-rays have been used at the Boston City Hospital no patient has been burned, nor have any untoward results occurred in about ten years during which radium has been employed there.

8. Man's Mental Evolution, Past and Future. H. Campbell.

**3. Growths in Gall-Bladder and Growths in Bile Ducts.**—S. Phillips notes that the only evidence to be expected of a growth in the gall-bladder is the presence of a tumor, often with a history of long-standing cholelithiasis. And there may be no tumor detectable in cases of soft growth projecting into the interior of the viscus. On the other hand, where the growth grows eccentrically the tumor may be enormous. Adhesions of the tumor to surrounding parts, interfering with its mobility with respiration, may render its identification as a gall-bladder tumor very difficult, and this identification may be quite impossible where the tumor invades and occupies the usual position of the liver. The cases of growth in the bile ducts contrast with those of the gall-bladder by the constant presence of jaundice without tumor; although, as Mayo Robson points out, catarrhal jaundice may occur in the course of growths of the gall-bladder, it is not the same early prominent symptom that it is in cases of gall-bladder growth which also give rise to tumor, and the difficulty of the diagnosis of growths in the bile-ducts is to distinguish them from growths in the pancreas rather than from growths of the gall-gladder. The occurrence of jaundice without tumor is an important indication that the disease is not a growth in the gall-bladder; and when with tumor of the gall-bladder there is jaundice the growth is probably not limited to the gall-bladder. A tumor of the gall-bladder with no jaundice gives hope that relief or cure may result from operation. And the frequency with which calculi are found with growths both of the gall-bladder and ducts is a strong reason for removal of gallstones by operation at the earliest possible moment.

**4. Dangers of Salvarsan Treatment.**—H. W. Bayly concludes that the risk of death is so small that if due care taken in preparation of the patient, and no errors are made in preparation of the solution of the drug, technique of administration, interval between injections, or subsequent treatment, fear of death cannot justifiably be advanced as a reason for withholding salvarsan treatment. The slight risk of serious complications or sequelæ is more than counterbalanced by the therapeutic results obtained. All sufferers from syphilis, in whatever stage, and all cases of early parasyphilis should, as a matter of routine, be permitted the advantage of salvarsan treatment.

7. Cesarean Section, with Especial Reference to the Rarer Indications for the Operation. W. H. Maxwell.

**1. Salvarsan in Pernicious Anemia.**—Byrom Bramwell reports the results in eleven cases of undoubted pernicious anemia, and in one doubtful case treated by salvarsan; of the eleven undoubted cases, four have been apparently completely cured—whether in these cases a relapse will occur or not the author is unable to say; in two cases there was very striking improvement; in one case there was very considerable improvement, but ultimately a relapse and death; in one case there was slight improvement and death from bronchopneumonia while under treatment; in two cases there was no improvement; and in one case slight improvement, the patient being still under treatment. The author has had nearly forty years' experience with the ordinary arsenical plan of treatment of pernicious anemia, and he believes that the salvarsan treatment is superior to the ordinary arsenical treatment. Further experience is, however, required before one can say whether the beneficial effects, which it undoubtedly produces in many cases, will be lasting or merely temporary. In giving salvarsan he has always given it intramuscularly, the dose used being 0.3 gram, which is half the dose usually employed in syphilis.

**2. Acute Perforation of the Gall-Bladder.**—L. R. Braithwaite states that as Sir Berkeley Moynihan has frequently pointed out, in every case of gall-bladder trouble provided the history is carefully noted, there is a complaint of flatulent indigestion over a long period. Attacks of severe pain in the region of the gall-bladder, with shivering fits of great or small intensity, may be present in nearly all cases in which there is an infection of any degree of severity. It is of great interest to find that the sudden agonizing pain characteristic of the rupture of a hollow viscus, followed by a zealous rigidity of the neighboring body wall, does not occur in all cases; probably both conditions depend to some extent upon the virulence of the invading bile. At the moment of perforation there is always severe pain in the region of the gall-bladder, followed in two or three hours by pain referred to the umbilicus. Moynihan showed how the fluid from a perforated duodenal ulcer gravitates over the bend of the hepatic flexure to the right iliac fossa; fluid escaping from the gall-bladder follows the same course, and gives rise to swelling and pain in the region of the appendix. It is a matter of much interest and of some importance to note that the effusion of a quantity of bile of a degree of virulence sufficient to cause a peritonitis will in the course of a day or two give rise to a definite fluid swelling simulating in every way an appendix abscess. The degree of rigidity is most variable and there is hardly ever the "marble" hardness found in other abdominal catastrophes. In none of the cases seen by the author has there been that degree

of involuntary stiffness and inability to move about seen in other grave abdominal conditions. It would appear that the absorption of bile from the peritoneal cavity slows the pulse-rate, just as absorption of bile in cases of jaundice reduces the normal pulse-rate. The pulse-rate after twenty-four hours will depend upon the virulence of the infection and the kind of peritonitis. The temperature may remain subnormal until the formation of an abscess or the onset of acute peritonitis.

4. **Concussion of the Spinal Cord.**—A. Newton presents the following provisional conclusions based upon his experiments: The spinal cord is extremely sensitive to slight degrees of concussion and compression; despite the slight anatomical changes demonstrable after lesser degrees of injury, the resulting disturbance of function is considerable; after concussion which has quite abolished motor efferent conduction, sensory conduction can still be demonstrated; arrest of the spinal cord circulation by aortic compression abolishes spinal cord function in from fifteen to thirty seconds; these experiments support the view that there is an organic basis for the signs and symptoms of "railway spine" and allied conditions of traumatic neurasthenia.

## Berliner klinische Wochenschrift.

*May* 19, 1913.

**Circumscribed Inflammatory Tumor Formation in the Abdominal Cavity.**—Von Schmieden refers to growths which originate in the omentum. The condition is a relatively new one, or rather newly described, and has sometimes imposed itself as a form of malignancy. Search through literature during the past few years has revealed but few cases, and the older literature has little or nothing which can be regarded as belonging under this head. The patients have been middle-aged, obese individuals, and the omental fat shows a central necrosis. One naturally thinks of such known conditions as strangulation of the omentum or of epiploitis plastica; but a study of the new cases shows that they possess a distinct individuality, as indicated by the title. The author describes one case in detail, and further terms them the Kuttner type, because that surgeon first worked out the individuality of the condition. The intimate nature and causal factors are still utterly obscure. Although inflammatory, no parasitic cause is yet in evidence. Central necrosis does not necessarily occur. The treatment is satisfactory because the masses are readily removed, and if neglected would certainly cause pressure symptoms. The blood vessels of the omentum seem to be concerned in the genesis of the masses (embolism, thrombosis, hemorrhage). Cases may have been masked as lues or actinomycosis.

**Rhinitis Posterior in Nurslings.**—Göppert mentions our increased knowledge of snuffles of nurslings, with especial reference to posterior rhinitis. He relates a specimen case as follows: Child aged 5 months; characteristic facial deformity and typical thorax of obstructed nasal passages. This was a permanent condition. Upon this basis the infant had developed in succession pneumonia, an angina an anterior rhinitis, bronchitis, more angina, repeated coryzas, and finally otitis media. The child was under observation seventeen months in all and the growth rate was much in abeyance. In such cases there may be a complete arrest of growth during the period of illness. In such cases, while there is swelling in the nasopharynx the actual site of stenosis is at the posterior choanæ. This furnishes a suggestion for radical cure by dilatation of the choanæ; a phenomenon which normally comes about of itself by the end of the first year. The author does not appear to favor forcible dilatation, nor curettage of the nasopharynx, and treats the mucosa with adrenalin and silver nitrate, in such manner as to prevent occlusion and secondary morbidity.

**Opening of the Lacrymal Sac Through the Nose in Dacryostenosis.**—West reports over 100 cases of this operation from Professor Silex's Berlin clinic. To reach the sac by the nasal route the author cocainizes the nasal chamber, and opening the inferior turbinal, chisels through the ascending process of the superior maxillary and the lacrymal bone to expose the distended sac; whereupon a new passage between eye and nose is established. This intervention has the advantage of reestablishing physiological conditions. Not only are the tears conducted away but if pus forms at any time drainage is already at hand.

*May* 13 *and* 20, 1913.

**Emin Pasha and the Mosquito Origin of Malaria.**—Sehrwald, who makes no allusion to more ancient theories of the mosquito origin of malaria, is content to show that Emin Pasha, physician, naturalist, and explorer, preceded Ross by about twenty years in demonstrating that mosquitos transmit the disease from man to man. He protected himself for many years by mosquito netting, and apparently never contracted the disease at all. According to Sehrwald's accounts, however, Emin never accused the mosquitos, but some kind of emanation from swampy land which could not penetrate the netting. It is therefore not surprising that Stanley regarded the netting in the light of a visionary notion, something to be laughed at. Stanley himself was always at work on the origin of malaria and made many recorded observations in regard to altitudes, still or running water, etc., and never once came near the mosquito theory; while all goes to show that Emin was equally in the dark, and did no more than wrap himself in netting while sleeping in swampy ground. To assert that Emin was the logical predecessor of Ross seems quite unwarrantable. Emin began his African sojourn in 1876, and when he met Stanley in 1888, had long been using the netting. A feature of interest not touched upon is the use of netting against the mosquitos alone. According to Schrwald's account, it could not have been an ordinary camp supply, but was taken along especially for Emin's own use.

**Successful Treatment of a Tonsillar Sarcoma.**—Wolze and Pagenstecher report the cure of an inoperable malignant tumor with the combined use of cuprase and the *x*-ray. The growth involved the right tonsil and pharyngeal wall, and was badly ulcerated. Patient, an elderly man, was much reduced in physical condition, due no doubt in part to interference with swallowing. The *x*-ray was unable to arrest the growth, either alone or combined with antimeristem. For the latter substance cuprase was substituted. The latter was at first tested alone, but without much success. It was then used in combination with the rays and the tumor began to undergo involution until its final disappearance, the patient in the meantime having resumed his occupation. The microscopic diagnosis of sarcoma had been made before the treatment, and at present only latent residues persist. The interval is naturally too brief to speak of a cure in the usual sense.

**Traumatic Rupture of a Cerebral Aneurysm.**—A condition hardly possible to diagnosticate in life from an ordinary extravasation of blood in the brain is reported by O. Orth. The diagnosis in this case was actually made before death by means of lumbar puncture. The case being one of fatal traumatism, had a medicolegal side. The patient had been a healthy man, aged 42, who worked for years as a stonemason, building towers. During this period he never was dizzy. He changed, however, to a lighter form of labor, and in the course of his day's work had but one straining effort to make, to wit, the carriage of a fifty pound load for some distance at 10 a. m. While so engaged he had seemingly an ordinary apoplectic stroke,

but no serious paralysis followed. A number of evidences of meningeal irritation developed and death occurred after 11 hours with Cheyne-Stokes breathing. Autopsy revealed a perforated aneurysm of the anterior inferior cerebellar artery of the right side. There were no evidences of any general diseased state of the arteries, and after injury the blood pressure had been but 120. There were none of the conditions which predispose to aneurysm. The latter was no larger than a pea, and its occurrence could not be explained. Forensically, death was due simply to trauma.

**Blood Pictures and Convulsive States.**—Jödicke emphasizes the necessity of drawing upon all our resources for differential diagnostic purposes. Thus we see one after another of the criteria which have served us in the past to distinguish hysteria from epilepsy prove untrustworthy with wider experience. It therefore occurred to the author to test various blood counts from this viewpoint. We have records of numerous labors concerning epileptic blood counts. The first step to ascertain referred to post-paroxystic leucocytosis—is it inevitable? The author has a large epileptic but small hysterical material, so that he chose more or less at random two cases of major epilepsy, one of petit mal and one each of hysterical convulsions and hysteroepilepsy. The finds were as follows: after each attack of essential epilepsy there was a leucocytosis, the count being over twice as high as in the intervals. This includes the case termed petit mal which also exhibited major attacks. The leucocytosis appeared after petit mal and abortive attacks as well as after major attacks. The two hysterical cases showed no leucocytosis after convulsive seizures. The research along these lines should prove of interest, and especially in relation to the affect epilepsies of Bratz and of Oppenheim. We are, of course, quite unable to pronounce as yet on the factors which make for leucocytosis at epileptic crises.

**Therapeutic Research Concerning Thorium Chloride in Animal Cancer.**—Caan is engaged in this research at Ehrlich's institute. In the first series two cancerous mice were injected with the chlorid. One who had an ulcerated tumor the size of a walnut died without any improvement, death probably the result of sepsis. The other mouse recovered. In a series of rats the experiments were marred. In the second series, in which both cancer mice and sarcoma rats participated, some animals were lost from infection, but there was a series of eight complete recoveries. In the third series several animals were likewise saved. In all these experiments the salt was injected locally, and the remedy will next be treated intravenously.

**Biological Diagnosis of Pregnancy.**—Stange of the Obstetrical Clinic at Magdeburg furnishes evidence entirely corroborative of Abderhalden's teachings concerning the serodiagnosis of pregnancy. He writes in part to offset some unfavorable testimony of recent date. At first he studied only the sera of surely pregnant women, seventy-three in number, and obtained a positive reaction in every case. Women who not known to be pregnant were not nearly as available, as it is by no means a simple thing to exclude pregnancy. The author is therefore not yet ready to report on this series. In the few cases thus far examined, with pregnancy surely excluded, all reacted negatively. Only the method of dialysis has been used thus far. Simple as it seems at first sight it is in reality a very subtle procedure with many chances for technical errors. The crucial point appears to be the condition of the placental fragment in regard to purity, a positive ninhydrin reaction showing the presence of foreign matter.

---

### Deutsche medizinische Wochenschrift.

*May 8, 1913.*

**Infectiousness of the Milk of Syphilitic Women.**—Uhlenhuth and Mulzer have taken up a question which a generation and much less ago was regarded as forever settled in the negative (after a prolonged controversy). Alleged cases of milk transmission had been shown to depend on actual lesions, and experimental results were negative. When the spirochete appeared on the scene it could not be discovered in milk. Nevertheless, disregarding the parasite, the authors began to inoculate rabbits with milk from syphilitic women and succeeded in causing the typical syphiloma of the testicles. To exclude accidental products from the nipples, the latter were sterilized, and the milk expressed manually or by a Bier cup. From 1 to 2 cm. of milk thus obtained was thrown directly into a rabbit's testicle, and in some cases a few ccm. of the woman's blood was also injected. The results were by no means uniform, but of special interest was the fact that milk from symptom-free women could produce positive results in the animals, while the corresponding milk of women with active syphilis might give negative results. Matters thus far stand as above and we can only contend that in a certain per cent. of cases the milk of syphilitic women can communicate the disease.

**Varicella in Adults.**—Krause has recently seen four cases of chicken pox in adults. Naturally the question of excluding variola became one of paramount interest. One case is described in which there is much to be said of local accidents, although the general condition was but slightly altered. In order to exclude smallpox the author ordered the patient vaccinated. Two vaccination pustules then duly appeared on the victim's arm. Patient had been successfully vaccinated in childhood. The author, having consulted various standard works, expresses his unbounded surprise that chickenpox in adults is almost ignored in some quarters, despite its great significance as a varioliform affection. Much space is taken in the effort to contrast variola with adult varicella, every modern resource being invoked. The points of dissimilarity are numerous and there is hardly any likelihood of confusion in typical cases. Borderline cases, however, must occur, and, generally speaking, we know all too little about varicella in adults.

**Correction of Lateral Curvature.**—This is nominally an article by Abbott of the State of Maine, U. S. A., but it appears in translation by Max Böhn of Berlin. The Abbott treatment of sclerosis appears to have aroused the greatest interest in Germany; and aside from this in another article, men like Vulpius and Joachimsthal have in a manner endorsed it as a revolutionary procedure of great promise. The matter is one of unusual interest. Dr. Abbott, who is active clinically in but a small provincial field, and who has published his doctrines chiefly in general medical weeklies, suddenly finds himself famous throughout the surgical world because he has built up a system of treatment which is actually antagonistic to the time-honored conception of the management of scoliosis. Long before he has had time to popularize his views in his own country we see him on the continent of Europe participating in the proceedings of the orthopedic societies. He is ignorant of the language of his hosts, who do their best to translate his English into familiar speech. It recalls the best days of Marion-Sims in his visits to Europe. Orthopedics, no less than gynecology, is an American subject, and Abbott seems to be repeating the conquests of Sayre in this field.

---

**Case of Trophic Changes of Obscure Origin.**—H. Campbell, M.D., reports the case of a woman, aged 26, in whom there occurred a disappearance of the subcutaneous fat from all parts of the body above the pelvic region. The intraorbital and mammary fat is retained. The fat began to disappear from the face when the patient was aged about six, and since then the process of absorption appears to have spread downward at the rate of about an inch yearly.—*Proceedings of the Royal Society of Medicine.*

## Insurance Medicine.

**A Letter to Examiners.**—The following letter to examiners, having as its object to secure an intensification of selection, was recently issued by Dr. W. H. King, Medical Director of The Fidelity Mutual Life Insurance Company of Philadelphia:

Dear Doctor: As a Fidelity Examiner you are the eyes and ears of the Company on the ground, the resident guardian of the Company's interests. You will, therefore, be interested in any information that would be of assistance in your work.

Of the total claims presented in 1912, fifteen, aggregating $24,000, occurred during the first policy year. Eighty-two claims, representing $155,796.60 were on policies less than five years old. If by intensified effort we can effect a 50 per cent. reduction in these figures—and this is a reasonable hope—you can see what it will mean to the Company and to our own record as an efficient medical corps. Deaths among the policyholders, especially in the early policy years, may be classified into two divisions, preventable and non-preventable. Accidental death or death from acute infectious disease may be considered as non-preventable. By elaborating any special hazard or unhealthfulness attached to an applicant's occupation, more than is usual for that occupation, you will enable us to appraise each case at its true value. Acute disease might be dismissed with the thought that an epidemic of typhoid or peculiar exposure to infection from this disease should be mentioned in your report. As regards malaria,—environment, social status, prophylaxis, sanitation, should be investigated and approved before you can rate the risk normal.

Passing then to the diseases that might be considered as preventable, let us first consider tuberculosis. You will agree with us that it is the unusual case that should die of tuberculosis within one year of its examination. Therefore, we ask your especial attention to this subject, realizing the vast importance of eliminating it as a factor in the early mortality of the Company. Naturally, if the applicant be underweight, or have a family history of tuberculosis, you will make a searching examination of the bared chest, using every means of diagnosis within your knowledge to eliminate any active process in the lungs or upper respiratory tract. Do not neglect the applicant's appearance. Accurately determine his height, weight and measurements. Take the blood pressure. Record the pulse and afternoon temperature. Tell us what effect his occupation may have on his longevity, and what effect his habits or mode of life, outside of working hours, may have upon him. Then exposure to infection should be carefully investigated. Each case in the near or remote family history should be given its actual bearing as a factor in infection, and the dates of death of each individual in the family that has died of tuberculosis or lung disease should be recorded accurately with the extent and intimacy of exposure to the applicant. The means employed to prevent the spread of the contagion, the thoroughness of the grasp by the affected household of what genuine prophylaxis means in caring for tuberculosis should have due weight in your study of the case. Any non-familial, incidental, or accidental, exposure should be investigated and given its true value. When you have searched a case of this character and feel sure that tuberculosis can be eliminated at the time of examination and the family history is given proper presentation, we can at the Head Office dispose of the case in a manner that would be fair to the applicant and to the Company, and avoid, as far as possible, the untimely deaths from tuberculosis.

Another group of the preventable diseases comprises those entrants dying from affections of the cardiovascular system. In this class fall the heavyweights. We must look to you to help us properly gauge the bearing overweight may have upon a risk. In the first place, if a man be above normal weight, his height and weight should be accurately obtained. The abdominal girth and the chest measurements should be carefully taken, and his general make-up accurately recorded. Is he broad-shouldered, muscularly built, with large limbs and large bones, or is he short-necked, with pendulous abdomen, flabby, his overweight due largely to fat, and not proportionately contributed to by the bony skeleton or muscular development? Such an applicant's habits regarding eating and drinking should be investigated. Is he a gourmand? Does he indulge regularly or to excess in the use of spirits or malt liquors? Is his occupation confining and contributory to the increase in weight? Is his size peculiar to himself or handed down from a long-lived ancestry? The blood pressure should be carefully taken, and the systolic and diastolic pressures recorded by the auscultatory method.. You will in this class of cases gauge as well as you can the functionating ability of the heart and determine as accurately as possible from the uranalysis the exact condition of this excretion. All of these factors, if properly presented, help in the satisfactory selection among the heavyweights.

Minimizing our losses from preventable diseases in the early years, presents a definite field in which we can work improvement. If you, the examiners, the first line in selection, will intensify your efforts in the examination, we at the Head Office will be better equipped thereby to decide equably for the Company and the applicant.

**Tuberculosis and Life Insurance.**—T. D. Lister notes that a life insurance company must consider the entire risk of liability to early death from tuberculosis on three grounds, one, two, or all of which may exist in the proposer coming before it. The first, or hereditary vulnerability, may be supposed to decrease during the course of life as a source of extra risk. The second, or acquired vulnerability, may be supposed to increase during life, if the proposer continues to be exposed to the causes of it. It includes drink, other poisons, chronic lung disease, and unhealthy environment. The third is a constant, striking at the natural resistance all through life, and is the danger of infection. This is possibly a little more intense in active adult life, and may be increased by many causes, such as co-dwelling with consumptives and poor physique, and, so little faith is there in the permanence of acquired immunity, by a past history of the disease in the proposer. So many individuals recover from tuberculosis without its being revealed during life, that a past history of revealed tuberculosis cannot be ignored. It means that the natural resistance broke down badly once. Why not again? The machinery has been proved to be defective or damaged. This point tends to be confused nowadays by the great number of "successful" cases of immunization, based on the injection of tuberculin.—*The Practitioner*, January, 1913.

# Book Reviews.

A System of Clinical Medicine. Dealing with the Diagnosis, Prognosis, and Treatment of Disease, for Students and Practitioners. By Thomas Dixon Savill, M.D., Lond. Third Edition. Thoroughly Revised. Price, $4.00 net. New York: William Wood & Company, 1912.

This book, written, as the title page announces, for students and practitioners, amply fulfills its purpose. It is a most ambitious work, almost entirely covering the range of medical diseases, and in addition chapters are given on examinations of pathological fluids and clinical bacteriology, and formulæ of useful prescriptions. This, the third edition, follows the same general plan and treatment of the subjects as in former editions, viz., approaching the disease to be discussed from the symptomatology to the cause or the disease itself. The cardinal symptom, or the symptom chiefly complained of by the patient, is first presented for study; accompanying symptoms following in natural order. Differential diagnosis is one of the strong features of the book, in short, it treats of the effects of diseases, working to their causes and diagnosis.

The work is arranged in a systematic manner; each group of related organs, or systems, with their associated diseases being given in separate chapters. Under each group, the cardinal symptom complained of by the patient, physical examination found under normal conditions followed by the diseased conditions with their differentiations, prognosis, and treatments, are given. The arrangement of the groupings of diseases is original, as shown in the chapters on the Abdomen, General Debility, and the Extremities. The work has been brought thoroughly up to date, and has been written in a scholarly, yet practical manner. The wonder is, how so much necessary knowledge can be given in such a concise but interesting way. The size of the book makes it convenient to handle, and the illustrations are exceedingly well chosen, sufficiently numerous to elucidate the subjects, yet entirely subordinate to the text—such not always being the case in medical works. The book is to be recommended as a decidedly practical, yet delightfully prepared work on clinical medicine.

Manual of Human Embryology. Written by Charles R. Bardeen, Madison, Wis.; Herbert M. Evans, Baltimore, Md.; Walter Felix, Zurich; Otto Grosser, Prague; Franz Keibel, Freiburg i. Br.; Frederic T. Lewis, Boston, Mass.; Warren H. Lewis, Baltimore, Md.; J. Playfair McMurrich, Toronto; Franklin P. Mall, Baltimore, Md.; Charles S. Minot, Boston, Mass.; Felix Pincus, Berlin; Florence R. Sabin, Baltimore, Md.; George L. Streeter, Ann Arbor, Mich.; Julius Tandler, Vienna; Emil Zuckerkandl, Vienna. Edited by Franz Keibel, Professor in the University of Freiburg, i. Br., and Franklin P. Mall, Professor of Anatomy in the Johns Hopkins University, Baltimore, U. S. A. In two volumes. Volume II. With 658 illustrations. Price $10.00. Philadelphia and London: J. B. Lippincott Company, 1912.

With the appearance of this second volume there is completed the most extensive textbook on purely human embryology. The high opinion expressed as to the first volume when it was published some years ago applies equally well to this. The most important chapters are those on the development of the nervous system, of the sense organs, of the gastrointestinal tract, of the vascular system, and of the urogenital organs. It is manifestly impossible to consider here in detail the contents of a volume of over a thousand pages with more than 650 illustrations. The chapters are divided about equally between German and American authors, and the translation of the German sections can be commended as highly satisfactory, with the exception of that by Grosser on the development of the pharynx and organs of respiration. Owing to the great subdivision necessary in assigning titles, the text is somewhat incoordinated and irregular in its value, but the questionable points are largely ones of opinion on subjects in which investigation to date cannot be considered as complete, owing to the lack of suitable human material. There is also considerable variation in the chapters as regards the value of the illustrations. For example, in the chapter on the development of the nervous system the cuts are almost all labeled with their legends, making it a very simple matter for the reader to understand at what he is looking without constant reference to the usual badly printed and occasionally erroneous key to the hieroglyphics attached to the figures, so often seen in embryological texts. In contrast to this the chapter on the development of the pharynx and organs of respiration, for example, has a number of cuts which have been taken from the German originals without alteration of the lettering. An important illustration is frequently labeled with the meaning of one or two of the key letters, while for the remainder reference is made to a previous cut. Unfortunately, they are not always found in the cut referred to, so that it is necessary for the reader to re-label the drawings for himself before the text can be read with any comfort. Why anatomists submit to such an imposition is difficult to understand, but there has been a crying need for reform in this direction for years, and as in this volume so much has been admirably done it is a pity to have even an occasional plate which sins against common sense. Such minor defects, however, do not in any way detract from the great value of this work which remains a standard book of reference for all teachers and investigators of human embryology.

A Textbook on the Practice of Gynecology. For Practitioners and Students. By William Easterly Ashton, M.D., LL.D., Fellow of the American Gynecological Society; Professor of Gynecology in the Medico-Chirurgical College, and Gynecologist to the Medico-Chirurgical Hospital, Philadelphia; formerly Lecturer on Gynecology in the Jefferson Medical College, Philadelphia; one of the Founders of the Congrès International de Gynécologie et d'Obstétrique; Member of the American Medical Association, etc. With 1050 new line drawings illustrating the text, by John V. Altender. Fifth Edition, thoroughly revised. Price, cloth, $6.50 net; half morocco, $8.00 net. Philadelphia and London: W. B. Saunders Company, 1912.

Five editions of this work have appeared during the past seven years—an ample test of its popularity. The present edition contains many changes and additions, a mere enumeration of some of which will suffice to show how the author has been quick to incorporate in his comprehensive treatise the most recent and advanced methods in the developments of modern gynecology. These changes and additions include the following: The blood in relation to surgery; De Keating-Hart's method of thermo-radiotherapy; the *x*-ray treatment of fibroid tumors of the uterus; the *x*-ray treatment of obstinate menorrhagia and metrorrhagia, and desiccation in the treatment of warty growths of the vulva. Fulguration as practised by De Keating-Hart is advised as a routine treatment in operations for cancer. The use of acetone and sulphate of quinine is advised in the palliative treatment of cancer of the uterus and vagina, and the use of Coley's toxins in the treatment of sarcoma of the genitourinary tract. The use of stock vaccines, as recommended in the treatment of gonorrheal vulvitis in children. The hormone theory is discussed in relation to puberty, ovulation, menstruation, and the menopause. These are but few of the many additions to this work. The section on operative technique is particularly full, and contains the most detailed directions for carrying out the various operative procedures. The work may be recommended to the student and practitioner as one of the best of its kind.

Kompendium der Röntgen-Therapie (Oberflächen und Tiefenbestrahlung). By Dr. H. E. Schmidt, Berlin. Third enlarged and revised edition. 80 illustrations. Price 5 marks. Berlin: August Hirschwald, 1913.

This book, the author states, is for practitioners who desire to get a general view of the subject. Within 228 pages he has given the essentials in a form easily understood, and at the same time has gone sufficiently into detail to give any one, not *au fait* with the subject, a fair working knowledge. There are numerous good illustrations.

The book is divided into two parts—technical and therapeutic. In the former the author discusses the consistency of Röntgen rays saying that they are probably a movement of mass, *i. e.* particles from the cathode. He describes their production, going into the details of the induction soil, hard, medium, and soft tubes. The hardness is measured variously, one method being by the measurement of the thickness of water will allow one-half through and absorbs one-half. In the therapeutic part the author begins with a short history of radiotherapy since the first empirical treatment of lupus. The general technique is described, placing the tube, etc. Then follows a résumé of the indications and possibilities in different diseases. Psoriasis, eczema, lichen, and severe cases of acne are treated with good results. In lupus and rhinoscleroma wonderful cures are achieved. Even leukemia is arrested, though not cured. Tuberculosis of bones and glands and fistulæ are cured. There is, however, no record of cure of an inoperable case of carcinoma, while on the contrary sarcoma is reduced. The book is excellent for those interested in this branch.

# Society Reports.

## AMERICAN THERAPEUTIC SOCIETY.

*Annual Meeting Held at Washington, D. C., May 5 and 6, 1913.*

(Special Report to the MEDICAL RECORD.)

DR. NOBLE P. BARNES OF WASHINGTON, PRESIDENT, IN THE CHAIR.

**President's Address.**—Dr. NOBLE P. BARNES of Washington, after treating of recent advances in therapeutics, spoke of the medical needs of the day, especially the need of a properly limited materia medica with a rational scientific classification for the use of lecturers, examiners and students. Many students were so confused in the study of pharmacology, so discouraged in memorizing the mass of details, that they failed to collect and retain the wheat and in due time became drug nihilists. If we would treat and practice only with the absolutely proven drugs, materia medica and therapeutics would be placed upon a sound and rational basis. Such a work should include only indispensable drugs and, so far as practicable, only those that had been assayed chemically or tested physiologically. The accurate knowledge gained from the study and use of these drugs would soon restrict the multitude of recognized and unrecognized remedies, give better control and better quality to these remedies, and enable the student to master everything from solubility to incompatibility, everything from methods of administration to variance in action.

**The Absurdities and the Commercialism of the Proposed Ninth Decennial Revision of the United States Pharmacopeia.**—Dr. OLIVER T. OSBORNE of New Haven said that among the articles that should have no place in the new Pharmacopeia were drugs having no therapeutic value, like lemon peel and saffron; metals and chemicals of little or no drug value, like aluminum hydrate and uranium nitrate; drugs not needed or whose effects could better be obtained from other drugs already official, like anthemis, cimicifuga, yerba santa, gambir, cottonroot bark, prickly ash, sarsaparilla, leptandra, etc.; preparations inferior to others, like fluid extract of digitalis (tincture better), fluid extract of gentian, fluid extract of cinchona; mixtures and compounds, like Basham's mixture, and elixir adjuvans; drugs that could not be standardized, like lemon peel. It was also unnecessary to include the parent substance just because it was desired to include a derivative, for example, the spices because it was desired to include their volatile oils.

Dr. HARVEY W. WILEY of Washington, D. C., said that no doubt some of Dr. Osborne's criticisms were justified, but there was a great difference of opinion upon this point among medical men. If 15,000 prescriptions were collected and it was found that one particular ingredient appeared in a considerable number of them, it seemed reasonable to conclude that the ingredient had some therapeutic value. Some of these humble drugs might yet become the headstone of the concern. Even if a plebeian were invited to the feast it would not hurt the others; the rest would be none the less good. Dr. Osborne had done much for the Pharmacopeia; it was a much better book than it would have been had he not been a member of the Committee. But it would be found to be a good book in spite of any defects that it might have.

Dr. OSBORNE did not think the 15,000 prescriptions a good test. The frequency with which a drug was used was no test as to its value.

**The Treatment of Diabetes in Pregnancy.**—Dr. REYNOLD WEBB WILCOX of New York said that if hydramnios existed, or the amount of glucose was excessive and uninfluenced by treatment, or the loss of flesh and strength was marked and, absolutely, if the fetus was dead, the uterus should be emptied at once. The viability of the child was usually problematical. A diabetic woman should not marry, or, if married, should not be allowed to become pregnant. If a pregnant woman became diabetic, the dangers of labor were increased, not only from impaired vitality and lessened resistance to infection, but because in severe diabetes a dead and even macerated child might result, or if the disease was mild, one of inordinate size. By successive pregnancies a curable might be converted into an incurable diabetes. Each patient should be carefully studied, and the procedure adopted that was justified by the condition of the patient and the persistence of the glycosuria. A case was cited in illustration.

Dr. ALEXANDER D BLACKLADER of Montreal, Canada, related two cases of diabetes of pregnancy: in one there had been no return of the glycosuria after term: the other had gone on to confirmed diabetes.

Dr. ROBERT T. MORRIS of New York said that many cases of glycosuria were due to pancreatitis and consequent squeezing of the islands of Langerhans caused by the effects of bacteria escaping from the duodenum. As soon as the pancreatitis was relieved, the glycosuria disappeared. The indication was to do away with infection if possible.

Dr. J. J. KINYOUN of Washington, D. C., said that in 200 autopsies at the tuberculosis hospital he had noted changes in the pancreas with squeezing of the islands of Langerhans in a considerable proportion of cases. Only in rare instances, however, had the patients given a history of diabetes.

Dr. OSBORNE of New Haven suggested that, according to good authority, uranium nitrate was a poison, particularly to the kidneys, and in his opinion it had no therapeutic value commensurate with its dangers.

Dr. WILCOX said that any danger there might be could be obviated by frequent examinations of the urine.

**The Treatment of Arteriosclerosis.**—Dr. LOUIS F. BISHOP of New York read this paper. Arteriosclerosis was the reaction of the individual to the proteins that caused the disease. It set in when something occurred in the individual to make him more susceptible to the disease. Accordingly, he had adopted the "few protein diet." All eggs, fish, meats, and soup, were excluded. Cheese was allowed as furnishing protein in a safe form, and later chicken was added tentatively. An ounce of castor oil was ordered every forty-eight hours for three doses, then another dose at the end of the week, and later a dose not less than once a month. Nitroglycerin was the great symptomatic remedy for all emergencies. Exercise and out-of-door life were essential. For the cure of the arteriosclerosis, the underlying causes should be removed, and among these mental stress was important.

Dr. J. MADISON TAYLOR of Philadelphia spoke of the importance of an early recognition of the disease. It was fortunate in some cases if the individual had some other form of breakdown, as then the arteriosclerosis might be recognized and treated in its incipient stages.

Dr. EDWARD D. FISHER of New York said that alcohol, over-eating, gout, etc., were only predisposing causes. Laboring men were especially susceptible to arteriosclerosis, but as a rule they were neither excessive eaters nor drinkers. But they were hard workers, and work and heredity were important factors in the etiology. Each one was given vessels good for a certain time under proper conditions; if he used them conservatively he might live out his allotted time; if he did not his life was shortened accordingly. A proper diet, open air exercise, a quiet life, and freedom from worry and care—all of these were important factors in the treatment. Diet should be regulated to meet the needs of each individual patient. It should not be too strict where the patient was weak, or when his occupation demanded great exertion. General principles of treatment should be broken as conditions necessitated.

Dr. MORRIS suggested that the response of the blood pressure to certain proteins might be utilized as a test for arteriosclerosis in its early stages.

Dr. BLACKADER said that while he could not help agreeing to a certain extent with Dr. Fisher as to heredity, it was a depressing view. He preferred to think that some individuals were more susceptible to certain poisons than others. Some children, for example, were poisoned by eggs. Such substances should be excluded from the diet of those susceptible to hardening of the arteries. Until the factors causing the disease were removed, treatment would prove unavailing. Treatment should be directed to the undue susceptibility of the tissues.

Dr. OSBORNE emphasized the danger of changing the diet too suddenly or radically. He had obtained good results from the use of potassium iodide.

Dr. SPENDER L. DAWES of Albany suggested that the salines or calomel were preferable to castor oil. He had found the after-constipating effect of the oil a decided objection to its use.

Dr. GEORGE HERBERT EVANS of San Francisco said that he was impressed with the frequency with which syphilis occurred in arteriosclerotic patients. Cases ascribed to overwork, overeating, etc., were not infrequently the results of syphilis. It should be eliminated as the causative factor treatment was instituted.

Dr. F. M. POTTENGER of Los Angeles said that typhoid fever was sometimes followed by hardening of the arteries. Some hardening was usually present in tuberculous patients after two years.

Dr. Kinyoun said that in the postmortem examination of tuberculous subjects he had found marked arterial changes in a considerable proportion of cases. They antedated the tuberculosis, however, and must be due to other causes.

Dr. Bishop said that in his experience no cause could be assigned in about nine-tenths of the cases. In the remaining tenth the cause was usually alcohol, syphilis, or one of the other factors ordinarily cited. Too much attention was paid to the advanced cases and not enough to the insidious cases, although the later were the most important. He did not believe in excluding all protein from the diet. Effort should be made to ascertain the particular protein causing the trouble and eliminate it. It was revealed by the special craving of the patient for it when it was withdrawn. He cited a case in illustration. As to salines, table salt and all salts were unfriendly to arteriosclerosis.

**Antityphoid Inoculations.**—Dr. F. F. Russel, Med. Corp, U. S. A., summarized the effects of antityphoid vaccination up to the close of the year 1912 in the U. S. Army, both at home and abroad, among the officers and enlisted men. During the last four years approximately 200,000 persons had been immunized, without fatalities or untoward results. The custom at present was to revaccinate at the beginning of each four year period of enlistment, not because all immunity had disappeared, but because it seemed unwise to trust to anything than the maximum immunity obtainable. Antityphoid vaccination had been a pronounced success in the naval and military services, in hospitals, schools, institutions, among pleasure seekers, and in contractors, especially those located on water-sheds; in fact, everywhere in civil and military life where it had been used. Its more general use, especially among the young, was advisable. The fact that it occasionally failed to afford complete protection was not a valid objection to its use, but rather an indication for its repetition, at intervals to be determined upon in the future. Its extended use would hasten the time when typhoid fever would become a negligible factor in our public health problems.

**Current Developments and Problems in Vaccine Therapy.**—Dr. A. Parker Hitchens of Philadelphia suggested that the limitations which at present characterized the treatment of infections by vaccines were not permanent and that further investigation would result in a wide extension of their field. After discussing autoserotherapy, regional infections, anaërobic bacteria, the preparation of vaccines, etc., the writer said that mixed vaccines were often of service in the common acute, subacute and chronic catarrhal inflammations of the respiratory mucous membranes. The most promising field of study for the laboratory man today was the relation of the infecting bacteria to the blood and lymph supply,—the possibility of bringing the antibodies formed as a result of the injection into contact with the infecting bacteria.

Dr. Osborne inquired with regard to the value of stock antistreptococcic and antistaphylococcic vaccines in pneumonia and urethritis.

Dr. F. E. Stewart of Philadelphia suggested that some of the good results reported after antityphoid inoculation might be due, in part at least, to modern hygienic methods, screening from flies, etc.

Dr. Kinyoun said that his experience with mixed vaccines had been unsatisfactory. The secret of success lay in determining the cause of infection in each instance as nearly as possible, and acting accordingly.

Dr. Hitchins said that there was authority for the statement that vaccines were of value in pneumonia. They failed not infrequently, however, and it was impossible to predict when this would occur. A hodge-podge or shot-gun vaccine could not be condemned too severely; but in some cases of mixed infection the indications were clear, and mixed vaccines could be used to advantage.

Dr. Osborne asked Dr. Hitchens whether he had had any experience with anti-rheumatic vaccination.

Dr. Hitchins replied that he had had none. If, however, rheumatism was caused by a specific germ and the antibodies formed as a result of the injection could be brought into contact with the bacteria, he believed that clinical results would be obtained.

**Neosalvarsan in Syphilis of the Nervous System.**—Dr. Edward D. Fisher of New York. This comparatively new remedy was an important aid in the treatment of syphilis of the nervous system, both in the early manifestations and in the so-called parasyphilitic forms of tabes and general paresis. It should be remembered, however, that after definite pathological changes had taken place neosalvarsan could have no effect beyond preventing the extension of the disease by the still active agents. Too much emphasis therefore could not be placed upon the importance of early diagnosis.

Dr. Kinyoun said that during the last two and a half years he had examined a number of tuberculous patients for syphilis, and had found a strong positive Wassermann reaction in about thirty per cent. of cases.

Dr. Fisher said that use of a new remedy like this so easy of administration was liable to be carried to extremes, and on this account he thought it well to sound a note of warning as to the small proportion of cases in which a cure could be expected after a certain point had been reached.

**Copper Chemotherapy with Special Reference to the Double Tartrate of Copper Oxide and Sodium.**—Dr. Wilfred M. Barton of Washington, D. C., said that the only compound of copper at present available for intravenous injection was a double salt such as the double tartrate of copper oxide and sodium. The minimum fatal dose in terms CuO was, for frogs (weight 30 gms.) 0.0005 gm., for rabbits (weight 1 kilogram) 0.0159 gm., for dogs (weight 3 kilos) 0.15 gm. The chief effects of poisonous doses were a primary stimulation and subsequent paralysis of the peripheral terminations of the motor nerves, involuntary muscle, and heart muscle. The solution of the double salt was powerfully antiseptic. One half c.c. of the solution of the double salt representing 0.0026 gm. of CuO could be injected intravenously into a rabbit weighing two pounds without subjective or objective symptoms.

**The Application of Some Muscular Tissue Adapted to Physiological Standardization.**—Dr. F. E. Stewart of Philadelphia, in collaboration with Paul S. Pottenger of Philadelphia, presented this paper. It was a preliminary report describing experiments for the standardization of fluid extract of ergot by measuring its physiological action upon non-striated muscular tissue. The muscular tissue of uteri from non-pregnant guinea pigs was used. The technique was explained in detail and the results shown upon charts.

**The Treatment of Pneumonia with Mercury and Sulphur Internally.**—Dr. Louis Kolipinski of Washington, D. C., had used teaspoonful doses of the following mixture: corrosive sublimate, ½ grain; precipitated sulphur, 2 drams; boiling water, 4 ounces. It was administered every two hours by day and three hours by night, for two or three days. When the thirty-second dose did not produce catharsis, half an ounce of castor oil was administered. When the evening temperature was normal and recovery began the mixture was given for several days at four to six hour intervals. Should no change in the symptoms occur by the end of the third or fourth day, the treatment had failed, and the cause would usually be found in a complication not previously detected or an error in diagnosis. The method had given good results in Dr. Kolipinski's hands.

**Recent Improvements in the Quinine Treatment of Lobar and Lobular Pneumonia.**— Dr. S. Solis-Cohen of Philadelphia said that apart from fresh air, dependence had been placed upon the following measures: First, the effective use of the very soluble hydrochloride of quinine and urea in 50 per cent. solution by intramuscular injection; second, the hypodermic injection of cocaine hydrochloride solution or an extract of the posterior lobe of the pituitary body for the maintenance of blood pressure; third, in cases of prolonged fever, delayed resolution, or tardy convalescence, the injection of bacterins (pneumococcus or "mixed" vaccines, personal or stock). The method of giving the treatment was described in detail. No invariable maximum limit had been fixed for the number of injections of quinine or of pituitary liquid, but it was not considered wise to continue the three-hourly injections beyond the first twenty-four, and in only a few cases had it been necessary to use them as long as this. Other measures were employed according to indication. In Dr. Solis Cohen's hands the treatment had reduced the mortality in the severe cases one-half, and the relief afforded in all cases was remarkable.

Dr. Riley questioned the use of the bichloride of mercury, as suggested by Dr. Kolipinski, particularly in old people, and in those suffering from renal disease. The method had only been employed to a limited extent, and further investigation would be necessary before arriving at a conclusion as to its value. Statistics as to the prevalence of pneumonia were somewhat unreliable and he was inclined to doubt whether there had been any notable increase in the proportionate number of cases as suggested by Dr. Solis Cohen. Quinine had been found to be a dangerous drug for hypodermic use. It had given rise to tetanus in a number of cases, even when given carefully and under antiseptic precautions. In explanation it

had been suggested that the tetanus spores existing in the patient otherwise innocuous, were aroused to activity by the injection. Anyway the procedure had not been found free from danger, and it was well to bear this in mind in deciding upon the injection treatment. He had obtained good results from the use of large doses of digitalis. Of late he had employed acetylsalicylic acid in combination with it.

Dr. Osborne said that he did not know of any one "best treatment" for pneumonia. The agents and methods to be employed depended upon the conditions present, and the treatment should always be adapted to meet the needs of the individual patient. Whether or not digitalis should be employed depended upon circumstances. He was opposed to employing it in every case as a routine practice. Its injudicious use had done serious harm in more than one case of pneumonia. When properly given, it acted perfectly. Quinine raised the blood pressure but its use was followed by a secondary reaction, and he was averse to giving a drug of this kind if he could help it. The use of the blood pressure apparatus in private practice had its drawbacks. Among other things it disturbed the patient and made him nervous, and it was doubtful whether the information obtained by its use made up for the disadvantages. About all it was necessary to know could be learned with the finger.

Dr. Albert E. Roussel of Philadelphia emphasized the importance of watching the blood pressure rather than the temperature in pneumonia. A pulse of 130 to 140 meant a failing heart and low blood pressure, and the chief indication was to raise the pressure. He had considerable faith in digitalis in these cases. If it failed, pituitary extract or some of the other drugs that had been mentioned could be used. He had recently used the treatment described by Dr. Solis Cohen in five cases of pneumonia with good results. The measures to be employed depended upon the conditions present in each individual case.

Dr. Evans said that the results obtained in the first case that he had treated by Dr. Solis Cohen's method were so satisfactory that he had subsequently employed it in others. The pituitary liquid gave a prompt increase in blood pressure. There was, however, no one successful treatment for pneumonia. The majority of cases went steadily on to one termination or the other in spite of any treatment that might be employed.

Dr. Pottenger spoke of delayed resolution in pneumonia. The examination of tuberculous subjects had led him to believe that the time required for resolution was much longer than was ordinarily supposed. If the disease was due to bacterial invasion and the proper vaccine could be used there should be a shortening in the length of the attack and in the time required for resolution. Success in treatment was chiefly due to individualization and the observance of minutiæ.

Dr. Kolipinski said that in the combination suggested by him the corrosive sublimate did not seem to act as a poison. He had given large doses of it without any injurious effect.

Dr. Morris suggested that the invasion of the grippe bacillus might account in part for the increase in the number of cases of pneumonia observed in recent years. Whatever method of treatment was employed, it should be given with confidence.

Dr. Solis-Cohen said that he had not met with a case of tetanus in over 5,000, possibly 10,000, injections. The element of confidence was undoubtedly of the highest importance. He believed that the increased mortality of the disease in later years was partly due to the wave of therapeutic nihilism that had spread over the world. Many of the patients might have recovered if they had been under the care of someone who had confidence in his own treatment. Under the treatment he had described defervescence usually occurred by lysis rather than by crisis. This, and the great relief afforded by the quinine without corresponding change in the pulmonary condition indicated that the treatment was antitoxic in character. It would seem as though pneumonia poison and the quinine counteracted or neutralized each other. In closing, he emphasized the fact that there was no treatment for all cases; and in individualization lay the key to success.

**Pulmonary Syphilis, with Report of a Case Promptly Responding to Specific Treatment.**—Dr. Albert E. Roussel of Philadelphia, after dealing with the distinctive features of the disease, and particularly the diagnosis from pulmonary tuberculosis related a case which had come under his observation. Female, colored, single, 24, admitted January 31, 1913; discharged April 1, 1913. Family history negative as to tuberculosis. Six weeks before admission there had appeared chills, fever, drenching sweats, cough with offensive muco-purulent expectoration and rapid loss of weight. Temperature for weeks reached 106°, and occasionally it would fall as low as 96.2°. Sputum negative. Percussion showed scattered but distinct areas of dullness over both lungs, particularly at right base; both apices were hyper-resonant, free from rales, and the seat of supplementary or puerile breathing; breathing was bronchovesicular and bronchial over the dull areas; vocal resonance increased; subcrepitant rales. Wassermann test positive. In March a gumma developed and a history of syphilis was obtained. Under vigorous treatment with mercurials and potassium iodide there was almost immediate improvement and rapid recovery.

Dr. Thomas E. Satterthwaite of New York said that at various times he had tried to bring up a discussion upon this subject. At first he could hardly get anyone to believe that there was such a disease as syphilis of the lungs. The cases were thought to be instances of pulmonary tuberculosis. The chief difficulty lay in the differential diagnosis. The rapid improvement under antisyphilitic treatment and a positive blood reaction were significant aids.

Dr. Pottenger spoke of the difficulty in making a correct diagnosis. The absence of tubercle bacilli was not conclusive evidence. Some tuberculous patients but rarely presented bacilli in the sputum. He cited a case in illustration. Whenever he suspected syphilis, he employed antisyphilitic treatment in addition to antituberculous treatment.

Dr. Osborne spoke of the value of potassium iodide from a diagnostic standpoint. It was contraindicated in many cases of pulmonary tuberculosis. If, however, there were no tubercle bacilli in the sputum it could be given and if, afterward, bacilli were found, the diagnosis was clear. The iodide seemed to increase the number of bacilli thrown out in the sputum.

Dr. Evans said that there was yet another affection that should be taken into consideration in making the differential diagnosis. He referred to lymphosarcoma and cited a case in illustration.

Dr. Morris related a case that was first diagnosed as tuberculosis of the lungs, then pulmonary syphilis, and which finally turned out to be a case of blastomycosis.

Dr. Pottenger said that he had used potassium iodide in many cases of pulmonary tuberculosis with beneficial effect.

Dr. Osborne said that according to his experience the iodide was liable to stir up the pulmonary condition in incipient cases and make matters worse. In chronic cases the effect was somewhat similar, but it enabled the patient to expel the bacilli.

**A Case of Influenzal Meningitis in the Adult Complicated by Pneumonia; Recovery.**—Dr. Thomas E. Satterthwaite of New York said the case was somewhat unusual in that it presented three types of grippe infection, the respiratory, the gastrointestinal, and the nervous. It was, so far as Dr. Satterthwaite knew, the only recorded instance of full recovery in influenzal meningitis. Male, 25, normal physique. There had been the usual symptoms of a mild influenza. When first seen he was unconscious, pupils irregularly dilated and irresponsive, breathing rapid and labored. Temperature 103.5°, pulse 138, respirations 26. Under bromides consciousness returned but there was restlessness and twitching of right leg and facial muscles. On the second day the signs of pneumonia were easily recognizable; temp. 105°, pulse 120, resp. 40; 300 grains of bromides were given during the day. On the third day there were nausea and vomiting, and on the fourth, vomiting of dark fluid and blood. Calomel 1 grain in divided doses; urotropin 10 grains in a pint of water, 30 grains in all during the day; strychnine sulphate 1/60 grain every four hours. Sixth day, low muttering delirium; bromides were given freely, urotropin suspended. Seventh day, camphor 3 grains in aseptic oil, hypodermically, every six hours. Strychnine continued. Temperature had fallen to 99°, pulse to 84, and respirations to 24. Tenth day, camphor suspended. From this time recovery was rapid and uneventful.

Dr. Stewart commented upon the infectious nature of the case. Some authorities recommended the use of camphorated water instead of the oil. He would like to see more study along this line.

Dr. H. B. Anderson of Toronto reported two cases of meningitis due to influenza. 1. Student had suffered for some years with ear trouble, but of late it had been quiescent. He was taken down with grippe and soon developed violent headache, restlessness, and delirium, and died after a few days. 2. Woman, 45; taken down with influenza of the ordinary type; while improving there suddenly developed marked symptoms indicative of meningitis, and she died after a few days. Lumbar puncture had failed to disclose the organism.

**Climatic Conditions in California and Their Influence**

**in the Treatment of Tuberculosis.**—Dr. George Herbert Evans of San Francisco, after describing the advantages of the California climate in respect to the treatment of tuberculosis, the writer pointed out that provision for adequate medical care should be a first consideration in sending patients away from home. The selection of a suitable climate, based upon a careful consideration of the needs of the individual case; a proper correlation of rest and exercise; attention to nutrition; tuberculin,—all of these were important factors in therapy. No theoretical argument, however, as to climate could weigh for a moment against the abundant testimony of successful treatment by men trained in the handling of these patients, irrespective of the locality in which they lived.

**What Does Treatment Offer to the Advanced Tuberculous Patient.**—Dr. Francis M. Pottenger of Los Angeles, after describing the clinical features of the disease in different stages, the paper dealt with treatment including the advantages of sanatorium treatment for chronic cases. A careful régime, suited to the individual and persistently carried out, was an important factor in the treatment. Failure often came from giving up too soon. A case was not hopeless so long as the patient could digest and assimilate food and the heart was capable of performing its functions. Early diagnosis and treatment were, however, of the utmost importance. The early tubercle was comparatively easy to heal but the disease became progressively more difficut to handle as it advanced.

Dr. Spencer L. Dawes of Albany emphasized the point that the patient, wherever he might be, should have careful, individual, medical attention. If one had to choose between care without climate, and climate without care, he would do well to choose care without climate.

Dr. Stewart agreed with the previous speaker upon this point. He had visited Dr. Pottenger's sanatorium, and could testify that much of his abundant success was due to the careful personal attention that he gave the patients individually.

Dr. Osborne said that one way to lessen the number of chronic cases was to secure an earlier recognition and treatment of the acute cases. Every patient recovering from pneumonia, typhoid and other diseases, and even those suffering from slight debility, should be carefully watched.

Dr. J. W. Chappell of Washington, D. C., said that tuberculous patients should never be given up. Recovery had occurred in cases that seemed absolutely hopeless. The physician could learn a lesson from the way the patients themselves held on to life. As to incipient cases, whenever he had a patient who was running down steadily without any known cause he strongly suspected tuberculosis.

Dr. John Blake White of New York emphasized the importance of early diagnosis and treatment.

Dr. Kinyoun said that any form of treatment that failed to restore the patient to his former physical condition fell short; for example, one that only enabled the patient to live and do light work in the place to which he had been sent, but not to return home, was a mere apology for a cure.

Dr. Morris said that surgeons often sent some of their patients (with tuberculosis of the knee for example) to an altitude of three thousand or four thousand feet and then to the seashore, and then to the mountains again, keeping this up for the beneficial effect upon the blood and circulation, but he had not heard that the method had been adopted or discussed by medical men. He requested information upon this point.

Dr. Pottenger said that the method was impracticable in pulmonary cases. The only salvation for these people was to find a physician in whom they had confidence and to stick to him. Changing and moving around from place to place was fatal.

**The Medical Treatment of Cholelithiasis.**—Dr. H. B. Anderson of Toronto said that while surgical procedure was frequently the best, and often the only, means of offering a chance of relief, its advocacy based on certainty of cure and assurance of non-recurrence was unwarranted. The object in view could often be obtained by non-operative treatment, especially in early and mild cases, and particularly after first attacks before serious local damage had been done by the infection. Medical treatment should be given when the patient's physical condition did not warrant operation, when operation was refused, as a preliminary to operation, and in all cases after operation to prevent reinfection and recurrence if possible.

Dr. Roessel cited an instance in which failure to provide proper post-operative medical care had been attended with unfavorable results.

Dr. Stewart suggested the treatment of cholelithiasis by bacterial vaccines.

**Orthotherapy; The Power Which Correct Posture, Organic Adjustments, and Mobility Exert upon Health and Its Recovery.**—Dr. John Madison Taylor of Philadelphia in this paper discussed the deformities caused by posture and costume and the ways in which they impaired the health. A conspicuous stoop, a lateral twist, a sagging waist, a hollow chest, etc., were often looked upon as merely evidences of bad taste or as finger marks of fate. Sometimes they were imitated and even exaggerated. They have a grave significance, however, when it was realized that they were capable of inducing degenerative changes in nerve centers or conduction-paths, morbid slackness in tissues, impaired nutrition in important structures, etc., all tending to produce even worse conditions in vital organs.

**Treatment of Splanchnoptosis, with Report of Cases.**—Dr. Elmer B. Freeman of Baltimore said that cases without adhesions, or with loose adhesions, could often be relieved by proper medical treatment. Cases with firm adhesions which caused a definite kinking or constriction of any part of the gastro-intestinal tract, with symptoms of chronic obstruction, required surgical intervention. Among the medical measures suggested in the paper were, exercises to increase the capacity of the abdomen and develop strong abdominal muscles, improvement of nutrition, the correction of gastric disturbance, the removal of constipation, and an increase in the nervous and muscular tone. Forced feeding, rest in bed, and the use of a suitable support might be required. The author preferred the corset recommended by Dr. Gallant some years ago.

Dr. A. Ernest Gallant of New York discussed the mechanical treatment of visceroptosis, and described the support referred to by Dr. Freeman.

Dr. Zueblin of Baltimore discussed the etiology, referring particularly to the importance of heredity as a factor. The indications were to remove the cause of the displacement, if possible, and furnish a support for the sagging organs. Effort should be made to improve the muscular tone by exercise, posture, massage, etc. Disturbances of the stomach and other organs should be corrected, if possible. Attempt should be made to improve the general nutrition.

**The Effect of Scarlet Red in the Treatment of Ulcer of the Stomach and Duodenum.**—Dr. Julius Friedenwald of Baltimore, in collaboration with Dr. T. F. Leitz of Baltimore, presented this paper. Scarlet red was a useful adjuvant in the treatment of gastric ulcer. While it could not replace the usual forms of treatment, when administered with them it increased the beneficial effect. It was particularly serviceable in the treatment of ambulatory cases. It did not interfere with the administration of other remedies, and indeed the effect of its combination with the alkalies or belladonna was at times most beneficial.

Dr. W. Wayne Babcock of Philadelphia spoke of seventeen cases of gastric ulcer with perforation that had come under his observation. In sixteen of them there had been no symptoms prior to perforation. Treatment was surgical. All of the patients recovered.

Dr. Morris discussed the surgical treatment of the cases with perforations.

Dr. Freeman had used the scarlet red in one instance. The spray was used over a period of eight days, during which the patient improved rapidly. The pain subsided and the symptoms disappeared.

Dr. Gallant spoke of the treatment from a surgical standpoint.

Dr. Friedenwald said that the thirty-seven cases treated with scarlet red were subacute cases. It was not a specific but it was a useful adjuvant.

**Newer Notes on the Subject of Peritoneal Adhesions.**—Dr. Robert T. Morris of New York presented this paper, which dealt with cobweb adhesions in the upper part of the abdomen, insidious in character. In many cases they were undoubtedly of toxic origin. Bacteria penetrated the wall of the bowel; as a result of irritation, the endothelium was shed and the lymph that exuded gave rise to more or less permanent adhesions. In some cases there was also hyperplasia of connective tissue which gave rise to firmer adhesions. The treatment of these insidious cases was chiefly medical.

Dr. Babcock suggested that there might be two kinds of these adhesions, one due to ordinary causes and the other to toxic influences. It was worthy of note that the old type of post-surgical adhesions were now but rarely seen.

Dr. Morris suggested that too much attention had formerly been given to the toilet of the peritoneum.

**The Dangers and Disadvantages of Spinal Anesthesia.**—Dr. W. Wayne Babcock of Philadelphia presented a paper based upon between 4,000 and 5,000 injections. The conclusions reached were in part as follows: Ether for general use remained the standard anesthetic in spite of its many disadvantages; the newer methods of anesthesia had a use restricted to those who had particularly qualified themselves; spinal anesthesia was dangerous in myocardial degeneration, particularly with obesity, and it should be used with care and avoided in grave shock and hypotonicity of the vaso-motor system; severe headache and abducens palsy might follow the use of improperly prepared solutions or a faulty method; excessive dosage, high point of injection, improper position or handling of the patient, might be followed by respiratory or circulatory arrest. If the patient could not be watched constantly for an hour after the injection, or if the operator was not familiar with the technique or was unprepared to meet emergencies, spinal anesthesia should not be used.

**Prolonged Precipitate Parturition Due to Disengagement of the Disproportionate Head.**—Dr. A. Ernest Gallant of New York related a case to illustrate the condition. Everything appeared to be all right but the head repeatedly came down and went back again and there was little, if any, actual progress toward delivery. When the baby did come, it came all at once. The delay was due to the disproportion between the size of the small head and the inlet. The remedy was to press the head down either by pressure on the fundus or otherwise. Several methods of managing the condition were described.

**Officers.**—The following officers were elected for the year 1913-1914: *President*, Dr. Howard Van Rensselaer, Albany; *First Vice-President*, Dr. Robert T. Morris, New York; *Second Vice-President*, Dr. Francis M. Pottenger, Los Angeles; *Third Vice-President*, Dr. J. Madison Taylor, New York; *Council*, Drs. Frederic H. Gerrish, Portland, Me.; John Blake White, New York; Clarence John Blake, Boston; Thomas E. Satterthwaite, New York; Francis P. Morgan, Washington, D. C.; D. Olin Leech, Washington, D. C.; Noble P. Barnes, Washington, D. C.; Edward D. Fisher, New York; A. Ernest Gallant, New York; J. Madison Taylor, Philadelphia; James C. Wilson, Philadelphia; Alexander D. Blackader, Montreal; Reynold Webb Wilcox, New York; Spencer L. Dawes, Albany; Lewis H. Taylor, Washington, D. C.

## NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

*Stated Meeting, Held January 3, 1913.*

Dr. George Woolsey, Chairman pro tem.

**Fracture of the Femur, Treated by Steinmann's Extension Method; Six Cases.**—Dr. John C. A. Gerster presented these cases. Two were pertrochanteric fractures of the neck; one occurred in a man, thirty years old, and showed a perfect result with no shortening, no displacement of the fragments, and good function. The other occurred in a man sixty-five years of age; the result was good, but there was not what might be called a perfect result owing to the premature discontinuance of extension. There was shortening of three-quarters of an inch and a slight coxa vera; flexion and extension were fair; internal rotation was limited, but the external rotation was good. Three were oblique fractures of the shaft in children aged five, nine, and eleven years, respectively. There occurred no shortening and there was perfect function in each case. The boy of five years was nailed on the twenty-first day and six pounds traction was applied. There was absolutely no interference with the joint function and to-day he was running around as well as ever. Dr. Gerster presented another case of a girl, seven years of age, with a supracondyloid fracture, one inch above the epiphyseal line, probably the result of direct violence. In this case there was no shortening and he obtained perfect function.

**Fracture of the Femur, Treated by Steinmann's Extension Method.**—Dr. Seth M. Milliken presented a man, fifty years of age, who was admitted to the Policlinic Hospital by ambulance on November 22. He had fallen in front of a car which ran over his right foot, thereby causing a traumatic amputation through the tarsus. On admission there was much swelling around the upper end of the right thigh and a shortening, on this first day, of one and a half inches. This shortening subsequently increased to two and a half inches. Steinmann's nail was introduced by Dr. Gerster three days after admission and an extension weight of 14 pounds applied; this was later increased to 20 pounds. The diagnosis had been made of a fracture through the shaft of the femur three or four inches below the trochanter. The traction gave him some pain in the hip at night, but during the day he was very comfortable. He had no elevation of temperature. The nail was removed on the twenty-first day. He made an uninterrupted convalescence. There was to-day but three-quarters of an inch shortening. The *x*-ray of the fracture was shown. There was now a passive flexion of 45 degrees. The patient entered the hospital six weeks ago. Dr. Milliken presented a second case that had been admitted to the Lincoln Hospital September 22. The patient tripped on a curbstone and sustained a fracture. A plaster-of-Paris cast was placed on the limb and the *x*-ray picture taken. The patient suffered greatly from asthma and emphysema, had a mitral insufficiency, and was in such a condition that the cast had to be removed. The fragments overlapped and there was one and three-quarters of an inch shortening. Because of the marked evert position of the limb the case seemed to be practically hopeless. A weight of 25 pounds was applied after the patient had been in bed six weeks. The fracture was about five inches below the tip of the great trochanter; the upper fragment was forward and overlapped about one and a half inches. The nail was removed on the twentieth day. A weight of 30 pounds was applied and the patient felt perfectly comfortable. To-day the patient weighed 270 pounds. The nail holes closed in five days and there was now about one-quarter of an inch shortening.

**Fracture of the Femur.**—Dr. Franz J. A. Torek presented an *x*-ray picture of a fracture of the femur just above the knee joint. The epiphyseal end was at a marked angle to the femur. There was a large triangulation between the upper and lower fragments. The nail, one of his own construction, was passed through the upper end of the tibia. There was an immense hematoma and Steinmann warned against placing a nail through hematomas. Extension was on for four and a half weeks. He found at the end of that time there was some mobility but no displacement. He then applied a plaster-of-Paris cast and kept it on until the middle of the seventh week. The *x*-ray picture of his result was shown. There was a large amount of callus. The man had been perfectly comfortable from the beginning to the end of the treatment and the results were good.

**Intussusception in an Adult; Resection; Recovery.**—Dr. Emily Dunning Barringer reported this case which came under her care in her service at the New York Infirmary in June, 1912. The patient had previously been admitted to the medical ward with the following history: She was sixty-three years of age, a widow, and gave a negative family history. She had been rather delicate in childhood, but since adolescence had always been well and strong until her present illness. Her menstrual history was normal and her menopause occurred at the age of forty-four. Her obstetric history was normal. She had had two children. For several years past the patient had suffered somewhat from shortness of breath and constipation, the bowels moving on an average of three to four times a week. There had been no history of diarrhea, jaundice, or goiter symptoms. She had been a hard working woman, a laundress, and had continued to work up to the time of her admission to the hospital. Her present illness began four months ago when she noticed that she had abdominal distress which she thought was due to the poor food she had been getting and, since that time, she had suffered from occasional cramps which, as she expressed it, "go across the upper abdomen." For the past two days they had been coming more frequently, were only fairly severe, and lasted a very short time. She relieved herself of the pain by pressure and rubbing the abdomen from above down. There had been no vomiting until two nights ago after a dose of calomel. Between these attacks of pain the patient would be entirely comfortable. She had been held in the medical ward for observation and diagnosis and the usual routine examinations had been carried out. The stomach analysis showed a normal condition. The blood examination showed a normal leucocytic count and the urine picture was negative. Examination of the heart and lungs proved negative. The abdominal findings had been negative for enlargement of the liver, spleen, and kidney, and no tumor masses had been observed. The vaginal and rectal examinations also proved negative. Constipation, however, had become almost complete and high medicated enemata failed to bring about a satisfactory fecal return. The temperature had ranged between 99° and 100° and the pulse between 90° and 100°. Vomiting had become a troublesome symptom; she vomited large quantities of fluid which was yel-

low or dark brown in color. On June 14, the patient suddenly became alarmingly worse, having an area of tenderness over the right inguinal region, frequent attacks of intense intestinal pain, and almost incessant vomiting. Realizing that some acute surgical situation had arisen, the patient was transferred to Dr. Barringer's service. When Dr. Barringer first saw the patient she found her to be an old woman, thin and wiry, with skin lying in loose folds suggestive of a recent considerable loss of flesh. She was obviously in great pain, though the pain came in paroxysms when the suffering seemed to be intense; in the interval she seemed to rest, being in a mildly stupid condition suggesting the toxic look of a beginning peritonitis. The abdomen was considerably distended and tympanitic and possibly slightly tender in the right inguinal region. No mass could be detected owing to the distension. During the paroxysm of pain coils of intestine stood out and visible peristalsis was quite apparent. The diagnosis of intestinal obstruction was made, but the cause was in doubt. Dr. Barringer ordered a high ox gall and turpentine enema, with absolutely no result. A rectal examination again was negative. She advised immediate operation, which the patient declined. At the end of six hours, when she was *in extremis*, with constant fecal vomiting, she consented. A median abdominal incision was made in the hypogastrium between the umbilicus and the symphysis and a gangrenous mass was found lying in the right inguinal region, obviously an intussusception in the lower part of the ileum. There were evidences of a beginning peritonitis. The patient's condition was so extreme that in spite of hypodermoclysis which was being administered it appeared doubtful whether the patient could live through the operation; therefore, an end to end anastomosis with the Murphy button was done, resecting the tumor mass; further exploration was made, the abdominal wound being closed as quickly as possible, allowing a small cigarette drain to remain. The patient was critically ill for twenty-four to thirty-six hours following the operation, but after the shock had passed convalescence was uneventful although somewhat slow, a certain amount of infection occurring at the site of the wound. This, however, healed satisfactorily, and she was discharged from the hospital in good condition, and was now in excellent health and spirits.

Dr. Howard Lilienthal said that these cases were exceedingly rare and that he had seen but two. One case promptly died; it was a dreadful case of gangrene. The other case was quite interesting. The patient was forty years old and had for many months suffered from symptoms of a mild intestinal obstruction. A mass could easily be felt in the upper abdomen and a diagnosis was made of a probable chronic intussusception. Monsel, an Australian surgeon, devised an operation which originally was intended for cases of this sort. This was the one employed by Dr. Lilienthal.

Dr. Frank J. A. Torek said that in adults the diagnosis of intussusception was quite difficult. He remembered one case that was sent into the hospital with the diagnosis of appendicitis and who got better in a few days; soon a recurrence took place and infiltration was noted in the ileocecal region. The patient again got better. The third attack occurred and a mass at the transverse colon was readily felt and a diagnosis of intussusception was easily made.

Dr. George Woolsey said he had had but one experience with intussusception occurring in an adult. These cases had been spoken of as not having symptoms similar to those found in children, that was, mucus and blood in the stools.

Dr. Barringer said that she saw the case only after the picture had been definitely shown.

**Overriding Fracture of the Femur; Open Reduction and Lane Plating; Non-Union; Removal of Plate and Introduction of Bone Graft from Tibia; Union.**—Dr. Walter M. Brickner demonstrated these cases:

Case I.—This patient was a young woman admitted in February, 1912, to Dr. Lilienthal's service at Mount Sinai Hospital with a six months old fracture of lower third of femur malunited with three inches of overriding, and considerable angulation. In spite of the marked contracture of the muscles Dr. Brickner succeeded by open operation in bringing the fragments into perfect alignment and good apposition. A Lane plate was applied with four steel screws, and then plaster dressing. Two months later slight bowing was noted and patient was put back to bed. In spite of subsequent treatment by massage and ambulatory splint, non-union persisted. Three and a half months after the first operation (which had been followed by primary union of the soft parts) Dr. Brickner re-opened the thigh and removed the plate, which had remained in place and the screws of which were not much loosened. Very little callus had formed. To excite bone production the operator cut an osteo-periosteal graft from the tibia of the same extremity, about three inches long by three-quarters of an inch wide, and in thickness extending almost into the medulla. This graft was then laid across the line of fracture along the outer side of the femur, the surface of which was freshened with a chisel. Periosteum and muscles were sewed over it and a plaster cast applied. Radiographs, taken at intervals thereafter, were exhibited, which showed the gradual bony fusion of the graft with the femur. The last radiograph, three months after the operation, showed no absorption whatever of the graft, which corresponds, as far as it goes, with MacEwen's contention that large bone grafts are not absorbed, as believed by Murphy and others. The operation was followed by solid union and excellent functional result, with shortening of only one-half inch.

Case II.—This patient was a lad about twenty years of age, whose case was a parallel to the first one, except that his fracture, in the midshaft of the femur, was a fresh one. He was admitted in April, 1912, to Mount Sinai Hospital, where, manual efforts at reduction failing, Dr. Lilienthal reduced the fracture by open operation and applied a Lane plate and a typical plaster dressing. A radiograph made a few weeks later, while the dressing was still in place, showed that in spite of the plate and the plaster there had developed marked forward angulation of the fragments. Seven weeks after the operation, careful examination revealed non-union. In June Dr. Brickner repeated in this case the same operation he had performed in the other. Here considerable callus was present, however, and no effort was made to overcome the angulation. In this case also solid union resulted, with but slight shortening and excellent function. Dr. Brickner remarked that in neither of these two cases, one a recent and the other an old fracture, had there been any infection or constitutional cause for non-union after the plating. He emphasized that the bone transplant was not used in any sense as a splint; it was not nailed or sutured to the bone nor placed in a trough, but merely held against the bone by suturing over it the muscles and periosteum. Its purpose was solely to excite osteogenesis at a place where this process had failed. Dr. Brickner said that the mere removal of the plates might have been sufficient to effect union. These cases were the first ones recorded, he believed, in which a bone graft was applied in this way.

**Ununited Fracture of Humerus in Obese Subject; Open Reduction and Lane Plating Under Local Anesthesia; Non-Union.**—Dr. Brickner reported this third case in which internal splinting was followed by non-union. The patient was a very obese man (350 pounds) who had been referred to the speaker for operation because of an ununited transverse fracture of the middle of the left humerus of one year's standing. There was no known cause for the non-union, except that the huge bulk of the man's short arm had evidently made immobilization impossible. The patient's obesity made him a likely candidate for post-operative pneumonia or other bad complication of a general anesthetic and he consented to undergo the operation under local anesthesia. Alypin was used in the skin line of incision and Schleich's solution to infiltrate the subcutaneous and muscular tissues. The great bulk of the arm made the exposure of the musculospiral nerve, the preparation of the fractured surfaces, and the introduction of the metal splint and plate, a tedious and difficult operation. Yet throughout it all the patient suffered no pain whatever, except from the constrictor placed above his shoulder and, momentarily, when the medulla was scooped out to receive the ends of an Elsberg intramedullary splint. This was used as well as a Lane plate for it was felt that neither alone would serve to keep the fragments aligned in such a fat and heavy arm. The extremity was dressed on a triangular axillary splint, with plaster bandages, which immobilized it fairly well. In spite of primary union of the soft parts the ultimate result was a failure, non-union, as before.

**Case Illustrating a New Method of Short-Circuiting for Colonic Stasis.**—Dr. Frank C. Yeomans presented this case:

Mrs. R., aged forty-eight years, consulted him in January, 1911. The birth of her first child twenty-one years ago was followed by "peritonitis," "uremia," and constipation. The latter has persisted to date and had been very severe the past five years, now requiring three cathartic pills at night and an enema in the morning to secure a movement. Physical examination showed a large well nourished woman. Owing to the thickness of the parietes nothing could be determined as to the abdominal viscera. The sigmoidoscope passed readily twelve inches

and showed a capacious sigmoid flexure. A radiograph was made by Dr. Cole, January 26, 1911, after an enema of bismuth in suspension. The bismuth passed up to a point on a level with the umbilicus. There was a long, tortuous loop of colon which passed up to a level with the first dorsal vertebra, and then turned downward on a line with the umbilicus, where there was apparently a marked constriction. There was a suggestion of the bismuth passing through the constricted area and slight indication of a descending colon and splenic flexure behind the distended loop. The diagnosis was: "Strong evidence of a constriction of the descending colon on a level with and about two and a half inches to the left of umbilicus. The long, distended loop is sigmoid." Confirmatory radiograph was made January 31, 1911. The diagnosis was: "Bismuth has only passed into the transverse colon. The long, tortuous loop which passed up to splenic flexure in the original plates now traverses the pelvis to the right side. There is partial obstruction of the descending colon near splenic flexure. From the lack of worm-eaten appearance one would be suspicious of adhesions rather than new growth." Operation was performed on February 10, 1911, at the Polyclinic Hospital. As the patient was very stout it was difficult to see the region of apparent obstruction. Adhesions might have been present, causing obstruction, but no growth, bands, or adhesions could be felt. The sigmoid, about three inches in diameter and twenty-four inches long, would of itself explain the symptoms. The problem, then, was to short-circuit the constriction in the colon and to drain the sigmoid. Though he had not heard of it before, it occurred to him that lateral union of cecum to sigmoid would be the correct surgical principle, leaving as it would no blind pouches for accumulation of feces, fermentation, and intestinal toxemia. Accordingly this was done by a double row of sutures eventful. The bowels were moved by oil enemas on the through a right rectus incision. Convalescence was uneighth day and the patient left the hospital on the seventeenth day. Since then she had had regular movements without enemas or cathartics and had enjoyed perfect health. The radiograph made October, 1911, eight months after operation, showed site of cecosigmoidostomy and that the bismuth had passed freely through the anastomosis, outlining the entire colon and sigmoid.

**Resection of Sigmoid for Acute Diverticulitis.**—Dr. John Douglas presented a patient who, two years ago after an exposure, had a severe attack of cramps below the umbilicus which was accompanied by marked abdominal distention. He had a second attack while in Boston. He then returned to New York after having been ill for ten days; he had then a temperature of from 100° to 101° F. and had pain localized mostly in the median part of the abdomen below the umbilicus. He then was comparatively well until January 5, 1912, when he had a similar attack of cramps, but this time more severe. Large quantities of salts and cathartics were given, but the bowels would not move. Dr. J. Finley Bell of Englewood, N. J., reported the patient as having a temperature of 101° F., pulse 100, a leucocyte count of 13,772, polymorphonuclears 76 per cent. The day following the temperature was 103° F., pulse 120, and polymorphonuclears 88 per cent. The pain had become more severe. From the symptoms presented it was believed that there was some acute inflammatory condition within the abdomen. Upon careful examination the abdomen was found to be slightly distended and tender. Rectal examination revealed a mass above the prostate and adherent to the posterior wall of the bladder. During the latter part of the attack there was pain on micturition and he complained of pain if gas rumbled through that portion of the intestine. A diagnosis of diverticulitis was made and an incision made in the median line. On opening the abdomen the sigmoid was found with an enormous thickening as the result of the inflammatory condition and an abscess of the mesosigmoid. The mesosigmoid was as thick as one's fist and adherent to the bladder. Pus escaped because of the abscess in the mesosigmoid. The question arose as to what was the best thing to do in such a case. There was so much thrombosis in the vessels of the sigmoid that it was believed that the only thing to do would be a resection. Then the question arose, what sort of anastomosis should be done? Mikulicz operation seemed to be indicated. In this case there was no acute obstruction or dilatation of the large intestine. He could not do a lateral anastomosis because the trouble was so low down. The choice, therefore, lay between an end to end anastomosis or an end to end anastomosis by the method advocated by Gibson, or the Mayo operation with resection of the rectum. An end to end anastomosis was done in this case. The drain was removed at the end of the fifth day. A fistula developed which was very slow in healing. Dr. Douglas said he presented this case because of an unusual condition and he wished to state that he believed that these cases were not as unusual as commonly supposed. These cases of diverticulitis had been anatomical curiosities for many years. In an encyclopedia published in 1904 the condition was spoken of to no extent. In 1906 an article was published reporting a case of acute peritonitis due to perforation of the diverticulum. In 1907 Mayo published an article in which he reported seven cases. In the London *Lancet* 109 cases were published, but most of them were only discovered at autopsy. Since 1907 to 1912, there had been ten or twelve articles published. In one report of 27 cases, the diagnosis was made in only seven before death occurred. In this report it was noted that in 25 per cent. of them carcinoma was engrafted upon the diverticulum. This condition was twice as common in men as in women. When the symptoms occurred, they were due to the inflammatory condition about the diverticulum.

**Partial Gastrectomy and Resection of Part of the Liver for Old Perforated Gastric Ulcer with Carcinomatous Degeneration.**—Dr. John Douglas presented these cases:

Case I.—The patient was a man, 30 years of age, a butcher by occupation. Twenty months ago he complained of water brash and indigestion, and soon he started in vomiting. In six months he complained of very severe pain which was occasionally relieved by vomiting and sometimes by eating. He only weighed 112 pounds. He had an ulcer of the lower curvature near the pylorus, and where the ulcer was there had been a perforation of the stomach. The liver had so been pulled down that it had become adherent to the stomach and closed the perforation. The tissue did not look like liver tissue at all, but was white and more like scar tissue. The ulcer was stony hard and it looked as though there was present a carcinomatous degeneration. He thought that the wisest thing to do would be a resection of the whole thing. A wedge shaped piece was removed from the liver and a posterior gastroenterostomy performed. The patient made a perfect recovery. The report of the pathologist was that there was present a carcinomatous degeneration, but the liver apparently was not involved.

Case II.—This patient was a Spaniard, 50 years of age, a carpenter by occupation. He had great difficulty in bending over in doing his work. His face was congested and blue as well as his right arm. There was a marked dilatation of the veins of the abdomen. When he entered the hospital he was much emaciated. The question of the cause of this condition came up. The *x*-ray showed a shadow in the mediastinum. The only explanation that could be arrived at was that there was some obstruction or pressure upon the vena cava, or possibly an obstruction in the azygos veins. The patient had complained of indigestion for twenty years, but the attack only became acute seven weeks ago when he began to vomit. The *x*-ray pictures were shown and bismuth was found to have remained in the stomach twenty-six hours after the bismuth meal. An operation was performed on November 12 and a carcinoma was found which was half again as large as one's fist. Of seven cases of carcinoma of the stomach that he had, six occurred in the same situation. The growth was adherent to the pancreas. In both the cases there was free hydrochloric acid present. The prognosis was bad. Out of seven cases there had been but one recurrence. All the patients gained from 18 to 35 pounds in weight.

**Experiences with Steinmann's Nail Extension Method in Fractures of the Femur.**—Dr. John C. A. Gerster read this paper. The method consisted in transfixing the soft parts and bone with a nail, the projecting ends of which formed the sole point of attachment for suitable traction upon the lower fragment. The duration of each traction was usually three weeks, exceptionally somewhat longer but never more than five weeks. All was done under the most rigid aseptic and antiseptic precautions. The method was indicated in recent fractures where the usual traction methods were not satisfactory, in compound fractures, in obese people, etc. Also it was indicated as a preliminary to Lane plating when the latter was indicated (interposition of soft parts, etc.). The absence of shortening or even increased length of the fractured limb greatly facilitated the technique of plating. In mal-unions of several months' standing with much contraction of the soft parts, the Steinmann method applied after breaking up of the mal-union was the only means of restoring such a limb to its original length.

**Cholecystostomy by Oblique Fistula.**—Dr. Joseph Wiener presented this paper in which he described the technique which he was now using in the operation of cholecystostomy. He stated that it had long been thought that if some of the drawbacks of cystotostomy could be eliminated by perfecting the technique of the operation much good would result. The drawbacks to cholecystostomy were: 1. Persistent fistula. 2. Post-operative pain and discomfort. 3. The reformation of stones. 4. Cancer. By their method the only cases of persistent fistula had been in cases of stricture of the cystic duct or empyema of the gall-bladder, and they no longer did cystostomy in these two classes of cases. It was largely to overcome this objection that they had developed the technique which they now employed. With regard to the post-operative pain and discomfort, it was evident that much of this pain and discomfort was due to the extensive adhesions resulting from suturing the gallbladder to the parietal peritoneum all around and using numerous gauze packings besides. They no longer fastened the gall-bladder all around to the parietal peritoneum and they were using less and less drainage. As to the reformation of stones, this might be said never to happen, or at least to occur very rarely, if all the stones were removed at the operation. With their technique they were now irrigating the gall-bladder through the drainage tube daily after the fourth or fifth day. In this way they had several times ducts following the operation. They had in several cases washed out small stones that came down from the hepatic acute cholecystitis that were not in good condition found the hepatic ducts packed full of small stones. To split up the hepatic ducts to remove every stone in such cases was to court disaster, but cases of this nature had been repeatedly cured by milking out as many stones as possible and irrigating the gall-bladder for ten days after operation. The danger of cancer developing in a gall-bladder that no longer contained stones or ulcer was, he believed, very small. In cases of gangrene or extensive ulceration of the gall-bladder, they regularly did a cystectomy. New growths, gangrene, extensive ulceration, empyema, stricture of the cystic duct, atrophy or marked hypertrophy of the gall-bladder, extensive pericystic adhesions, all had been rightly mentioned as indications for cystectomy. But there were a goodly number of cases that did not come under these categories in which the operation to be described was suitable. Their usual technique was to palpate the liver under deep anesthesia. If this organ did not extend below the free border of the ribs their incision started just below the free border. If the liver reached further downward, they started the incision from a point opposite the lower border of the liver. If they were in doubt about the lower border of the liver they made a very small incision well below the free border of the ribs. The object of all this was to avoid making an unnecessarily long incision. The incision was carried through the skin and anterior sheath of the rectus, the fibers of the rectus were bluntly separated, and the posterior sheath of the muscle and the peritoneum were incised. The first incision was always a short one and was used for exploration with two fingers. The incision was then enlarged upward or downward and the gall-bladder and ducts carefully palpated. If the gall-bladder was distended, it was emptied by a syringe or a small trocar, after packings had been carefully placed about the gall-bladder. A small incision was then made into the gall-bladder near its fundus, at the site of the aspiration, the remaining contents being squeezed out and mopped away. Then the gloved finger was inserted into the bladder, stones still remaining were removed, stones in the duct were, if possible, milked back into the bladder and removed. A large new catheter or rubber drainage tube was then introduced into the gall-bladder, sometimes into the cystic duct, or even into the duodenum. The incision was made into the fundus of the bladder so that when the bladder contracted the drainage tube would still be below the free border of the ribs. They now established an oblique fistula by suturing the tube into the bladder as they did in performing a Witzel or Kader gastrostomy. If the exposed area of the bladder was long and narrow, they used the Witzel methods of suture; if the area was wide and not very long, they sutured according to Kader. The result in either case was the same. They now used plain catgut exclusively for these sutures. They usually passed one suture partly through the wall of the bladder and through the tube to make doubly sure that the tube would remain in place. They no longer sutured the gall-bladder all around to the parietal peritoneum. Very little drainage was necessary. They formerly used gauze packings around the bladder, but with increasing experience they found that in most cases a drain of rubber dam placed under the fundus of the gall-bladder was all that was needed. They sometimes closed the abdomen with three layers of sutures, plain gut for the peritoneum, chromic gut for the rectus and its sheath, and silk for the skin. Often they used only two layers, through and through number three chromic gut sutures to include all layers except the skin, with a few fine chromic sutures for the anterior sheath of the rectus, and silk for the skin. After the fourth day the gall-bladder was irrigated daily with saline or a weak astringent solution. They believed that these irrigations shortened the time of convalescence, removed inspissated bile, and small fragments or even complete stones. The drainage tube was connected with a bottle attached to the patient's bed. The first dressing was done on the seventh or eighth day, when the rubber dam drain was removed. They usually removed the tube between the tenth and fourteenth day, being guided somewhat by the character and amount of bile being drained and also the general condition of the patient. The patient got out of bed about the twelfth day and left the hospital, usually with a superficial sinus, about the twenty-first day. They had given up extensive gauze drains as they were not necessary with this technique and they undoubtedly delayed convalescence. They had also found that if gauze or rubber dam drains were left more than a week after the operation the healing of the wound would be delayed. To get the best immediate as well as remote results, attention to all the apparently unimportant points mentioned was, they believed, essential. As regards the immediate results of operation, they considered the duration of the operation as of the greatest importance. They had computed the average time consumed in doing their cholecystostomy operation during the past four years, and found it to be less than thirty-nine minutes. In many of the earlier cases they sutured the gall-bladder to the peritoneum which took several minutes and this they now dispensed with, thus shortening the time of operation still more. After citing a number of cases in which this operation was done, Dr. Wiener declared that the operation offered the following advantages: 1. Low mortality. 2. Low morbidity. 3. Retained function of the gall-bladder. 4. Rapid healing. 5. No danger of permanent fistula. 6. Ease of second operation. 7. Great advantage in icterus as benefit was derived from drainage as long as the tube was left and also because not a great deal of dissection was required and hence there was less danger of post-operative shock and hemorrhage. 8. There was no leakage along the tube and very little or no packing was needed which meant much quicker healing. They recommended this procedure to others for trial in suitable cases with every assurance that they had presented this matter impartially and had not overstated the case.

**The Relief of Intractable and Persistent Pain Due to Metastases Pressing on Nerve Plexuses by Section of the Opposite Anterolateral Column of the Spinal Cord, Above the Entrance of the Involved Nerves.**—Dr. Edwin Beer made this preliminary report from the Fourth Surgical Division, Bellevue Hospital: Dr. W. G. Spiller had suggested the operation of cutting the anterolateral column of the cord for the relief of persistent pain of organic origin and published the first case illustrating this procedure, the operation being performed by Dr. E. Martin. The importance of obtaining relief for these cases was self-evident and having seen a number of such cases dragging out their sufferings over months, more or less chronically poisoned with morphine, the suggestion of Dr. Spiller appealed to him. Compared with cutting of a large number of posterior roots to effect a similar result, it seemed a much simpler and safer procedure. Moreover, if the physiology was correct patients so operated on would lose only pain and temperature sense in the affected parts, whereas section of the posterior roots produced loss of all three sensibilities. In the patient Dr. Beer reported, the persistent right-sided pains stopped at once after section of the left anteroposterior column at the level of the tenth dorsal lamina. The relief obtained was most striking and as the patient was walking about eleven days after the operation, a more satisfactory outcome could not have been desired. Dr. Beer concluded that: (1) Surgically considered, the operation of cutting the anterolateral column without doing serious damage to the rest of the spinal cord was perfectly feasible and not difficult. (2) Therapeutically considered, the freedom from pain produced by this surgical intervention met the indications presented in the case reported and in many other sufferers a similar intervention, he felt sure, would give a similar relief. (3) Physiologically considered, complete section of the anterolateral columns produced (*a*) loss of pain sense on the opposite side of the body, (*b*) a disturbance in the thermal

sense which suggested that the fibers for heat and cold were dissociated in the cord, and (*c*) right-sided disturbance of deep pressure sense and the slightest disturbance in touch sense, both being impaired, without producing any disturbance of the sense of position.

## Books Received.

## Therapeutic Hints.

**The Treatment of Lupus Erythematosus.**—C. Sabatié details his method of treatment as follows: During the acute attacks all active treatment is avoided, and soothing ointments, such as cold cream, glycerite of starch, etc., are applied to the lesions. The constitutional treatment is directed against the vasomotor element. For this purpose the following is administered:

℞ Quinine sulphate,
Ergotin, āā 0.05 gram.
Extract of belladonna, 0.001 gram.

This should be given in pill form, six to eight times a day.

For the centrifugal form of erythema there should be lightly applied to the diseased patches every other day by means of a cotton swab the following mixture:

℞ Tincture of iodine,
Acetic acid, equal parts.

Or the lesions may be painted every other day with the following:

℞ Precipitated sulphur,
Resorcin, āā 5 grams.
Tincture of green soap (20 per cent.), 30 grams.

For the first application this should be diluted with an equal part of eau de Cologne; later it may gradually be employed pure.

The following ointment is useful:

℞ Biniodide of mercury,
Iodide of potassium, āā 0.10 gram.
Lard, 20 grams.

The proportions of the medicaments may be gradually increased.

All of the above applications are designed to produce an irritation which should not be excessive, and should be suspended when the irritation is too great. In this case they should be alternated with soothing applications.

Scarifications are of distinct value. They should be superficial and regular and should form a square pattern. This form of treatment should be applied once a week.

For the fixed variety of lupus erythematosus the same treatment, but of a more energetic degree, should be applied. The scarifications should be deeper, and may be supplemented by the application to the scarified areas of a ten per cent. solution of lactic acid.

Various physical agents have demonstrated their value in these conditions. The high frequency currents are indicated above all in the centrifugal form of erythema. The maximum effect is obtained if the high frequency currents are applied in conjunction with and immediately following the scarifications. Photo-, radio-, and radiumtherapy furnish good results, but occasionally the reaction is too strong and is followed by an extension of the disease. The use of these measures should be restricted exclusively to the fixed type of lupus erythematosus.

One of the best forms of treatment is the application of carbonic acid snow for ten to twenty seconds in such manner as to produce an ulcer and a superficial eschar; as soon as this is healed, in about fifteen days, the application is repeated.

Although many methods of treatment have been employed against it, lupus erythematosus may persist in spite of all treatment. —*Le Progrès Médical*, April 26, 1913.

### INCOMPETENCY OF THE ILEOCECAL VALVE.

#### DISORDERS ARISING FROM THIS CONDITION AND THEIR TREATMENT.

By JOHN H. KELLOGG, M.D.,
BATTLE CREEK, MICH.

Of the more important structures of the body, the ileocecal valve seems to have been most of all neglected. This interesting structure was discovered by Caspard Bauhin in 1579.[1]

Piccolomini published an account of the valve as described by Bauhin in 1586.[2] Tulpius wrote about the ileocecal valve in 1641.[3] Veslingio published a description of the valve with a rude drawing in 1676.[4] (Fig. 1.)

John Mason Good in his "Study of Medicine" (1822)[5], described the ileocecal valve as a "muscular structure" and recognized its double function. He stated its use to be "To moderate the flow from the small intestine into the latter (colon), and to prohibit a regurgitation of the feces into the former (small intestine)."

Kopsch, the German anatomist, describes the ileocecal valve [6] as consisting of two folds which act as do the two folds of the mitral valve of the heart, permitting the intestinal contents to move forward but not backward.

Cunningham calls attention to the fact that the ileocecal valve is formed by a partial inversion or telescoping of the small intestine.[7] Cunningham also notes the fact that the valve varies considerably in form. Viewed from the interior of the colon it may be either rounded or slit-like and with sloping or infundibuliform edges.

Common forms of the ileocecal valve are shown in Figs. 2 to 4.

Kraus and other German anatomists note that the human ileocecal valve owes its structure to the fact that the cecum is folded around the end of the ileum as shown in Figs. 5 and 6.[2] This form of the large gut which is found only in man and the higher apes is produced by a muscular band, the *habenula* (Fig. 6), which passes behind the valve, puckering the large gut so as to form several folds about the end of the ileum, a series of haustræ, thus producing an intussusception of the small intestine. This intrusion of the small gut into the large gives rise to the folds which form the mechanical structure of the valve (Fig. 18).

*The Physiology of the Ileocecal Valve.*—Although the muscular character of the valve was recognized by John Mason Good nearly a century ago, the fact that the valve is not only a mechanical structure but a true sphincter was apparently forgotten until suggested by Keith in 1903, and proven on the dog by Elliott in 1904.[8]

That the integrity of the ileocecal valve is essential to health may well be inferred from the fact that it is almost universally present in vertebrate animals. (Figs. 7 to 10.) The ileocecal valve serves to separate the mid-gut from the end-gut just as the pylorus forms a line of demarcation between the fore-gut and the mid-gut. The small intestine or mid-gut is the principal organ of digestion and absorption. The contents of the small intestine are held back by the ileocecal sphincter until the digestible portions of the food have been digested and absorbed. Carbohydrates are practically all absorbed in the small intestine, only about two per cent. passing into the colon. A somewhat larger proportion of fats escape absorption, and a still larger amount of protein.

The colon is a receptacle for unused ingesta, mucus, bile, and various excretory products. These materials readily undergo putrefaction in the large intestine under the influence of warmth and moisture, and of the presence of putrefactive bacteria which abound in this part of the alimentary canal.

Says A. Schmidt: "Fermentation of carbohydrates takes place normally both in the lower part of the small intestine and in the colon. *Putrefaction of protein on the other hand occurs exclusively in the large intestine. The ileocecal valve forms a sharp line of demarcation above which putrefaction never occurs except under pathological conditions.* If protein decomposition extends up into the small intestine, far greater quantities of indican appear in the urine than ever occur through the absorption in the colon."[9]

Sir William Macewen enjoyed the rare opportunity to make numerous observations upon the behavior of the ileocecal valve in a case in which the valve was exposed to view through a large opening in the cecum and abdominal wall. He noted that material passes through the valve from the small intestine into the colon in small quantities at a time and in the intervals between discharges "the ileocecal valve seemed to close, probably by reflex action."[10]

"It appears to me," Sir William added, "that at the ileocecal valve there is a controlling reflex agency regulating the flow of partially digested food into the cecum."

The recent observations of Cannon[8] clearly demonstrate that the ileocecal sphincter acts in a manner very similar to the pylorus, retaining the foodstuffs in the small intestine until the digestive work of the mid-gut is complete and the digested foodstuffs have been absorbed.

Within the last few years Holzknecht, Schwartz, Groedel, Case, and numerous other roentgenologists have clearly demonstrated the functional activity of the ileocecal valve in controlling the movements of foodstuffs from the small intestine into the colon. These observations establish the necessity of the ileocolic valve for the following purposes:

1. To hold back the digesting material in the small intestine until the digested portion has been transformed by the several digestive juices and absorbed.

2. To pass the mixture of unusable food residues,

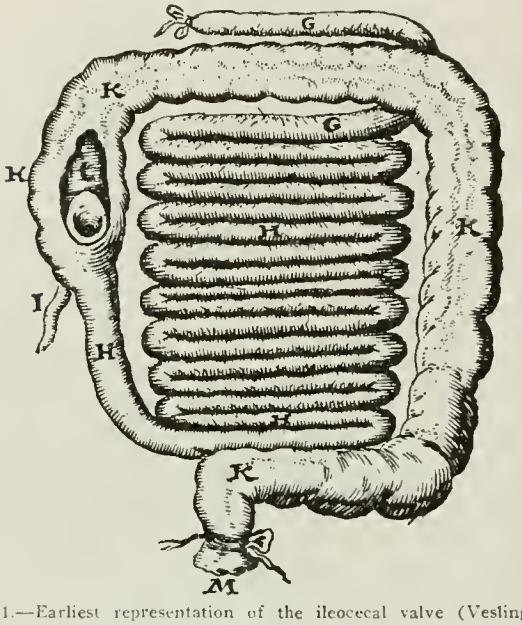

Fig. 1.—Earliest representation of the ileocecal valve (Veslingio).

mucus, bile, and other excretions from the small intestine into the colon in small successive doses so as to give the colon, the chief function of which is the absorption of water and the discharge of unusable food residues and excreta, an opportunity to deal with the successive portions of material brought to it without being overloaded. (The contents of the small intestine are nine-tenths water when passed into the colon.)

3. To prevent a reflux of material from the colon into the small intestine, which is accomplished by cooperation of the muscular sphincter of the proximal side and the mechanical action of the membranous folds on the distal side of the ileocolic junction. The importance of this function of the ileocecal valve is greatly emphasized by the demonstration by Cannon, Schwartz, Hertz, Case, and others, of the existence of an antiperistaltic action in the proximal half of the colon. Cannon gives[8] a most graphic description of the powerful anti-

Fig. 2.—Normal ileocecal valve (Cunningham).

peristaltic waves (as seen in the cat) beginning at about the middle of the transverse colon and passing rapidly backward along the colon to the cecum, compressing the liquid contents of the cecum so strongly as to cause a backward rush through the advancing ring of constriction. Case has confirmed these observations in the human subject.

The tight closure of the ileocecal valve alone prevents the contents of the cecum from being forced by these powerful antiperistaltic waves backward

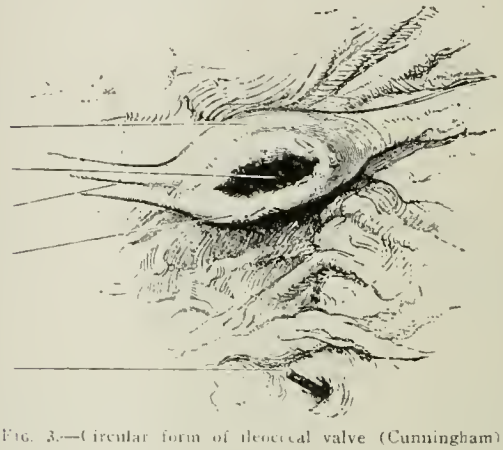

Fig. 3.—Circular form of ileocecal valve (Cunningham).

into the small intestine. At intervals the antiperistaltic waves cease momentarily while the ileocecal valve relaxes and small portions of material are passed into the cecum from the small intestine; then the antiperistaltic waves again begin churning the liquid material, spreading it over the surface of the cecum and ascending colon, thus encouraging absorption while at the same time exerting a pumping action upon the venous and lymphatic vessels so that the contents of the cecum are rapidly dried down to the proper consistency. Fig. 11 is a reproduction from a radiograph of a colon in which colitis existed in the ascending colon with exaggerated antiperistalsis, as shown by the great accumulation of material in the cecum and ascending colon.

Of these several and important functions of the valve, Cannon says: "It gives new meaning and value to the location of a sphincter or valve at the opening of the ileum. For, inasmuch as the valve is normally competent, the constrictions repeatedly coursing toward it force the food before them into a blind sac. The effect on the contents must be the same as the effect seen in the stomach when the pylorus remains closed before the advancing waves. . . . About twenty-five waves in the cat affect

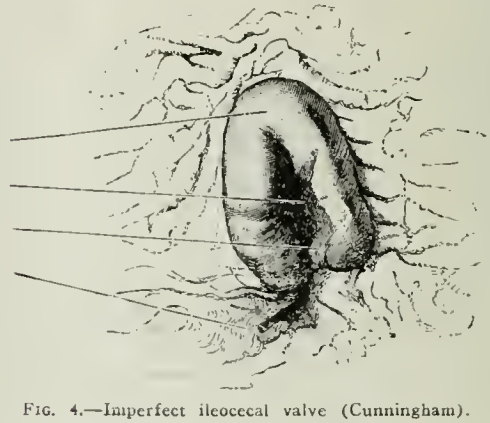

Fig. 4.—Imperfect ileocecal valve (Cunningham).

thus every particle of food in the colon during each normal period of antiperistalsis."[8]

Each of the two functions of the valve is of essential importance to the integrity of the digestive functions and the welfare of the body.

*Morbid Conditions Which Arise from Incompetency of the Ileocecal Valve.*—That the ileocecal valve may become incompetent was recognized by John Mason Good, who called attention to the fact that fecal vomiting could not occur unless the ileo-

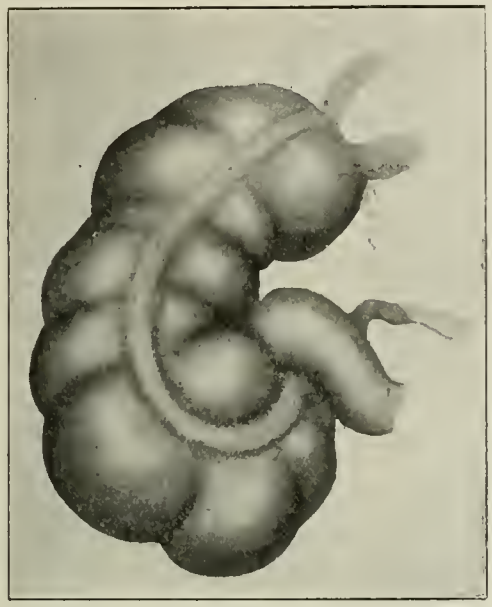

Fig. 5. Normal cecum and terminal ileum.

cecal valve had become incompetent.[5] Moreover, Max Hertz of Vienna, in 1897, demonstrated that the ileocecal valve frequently becomes incompetent, and pointed out some of the disorders which arise from incompetency of the valve.[11]

A. Schmidt of Dresden, some years later,[9] called attention to the evils resulting from incompetency of the ileocecal valve and recently roentgenologists have shown that the bismuth meal shows incompetency of the ileocecal valve to exist in a very con-

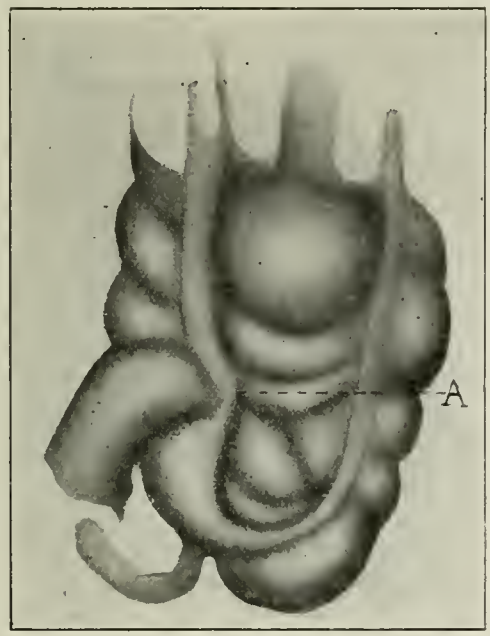

Fig. 6.—Normal ileocolic junction, bowel rotated outward showing habenula, A.

siderable proportion of cases. Holzknecht found the valve incompetent in three out of fifteen cases studied with the bismuth meal. Case found the valve incompetent in 33 cases of 200 examined, or one in six.[12]

The writer's attention was first called to the frequency with which incompetency of the ileocecal valve occurs by Dr. J. T. Case, the roentgenologist of the Battle Creek Sanitarium, in November, 1910. A study of the subject since that time has convinced

Fig. 7.—Ileocecal valve of a dog.

the writer that this morbid condition is one of considerable importance not only in relation to pathological disturbances of the alimentary canal, but also numerous varied and serious functional disturbances and degenerations elsewhere in the body.

The opportunity for making the extended study of clinical cases upon which this paper is based has been afforded by the thoroughgoing scheme of roentgenological study of the alimentary canal perfected by Dr. Case, whose interesting observations have been reported before several scientific bodies in this country and Europe, and published in various

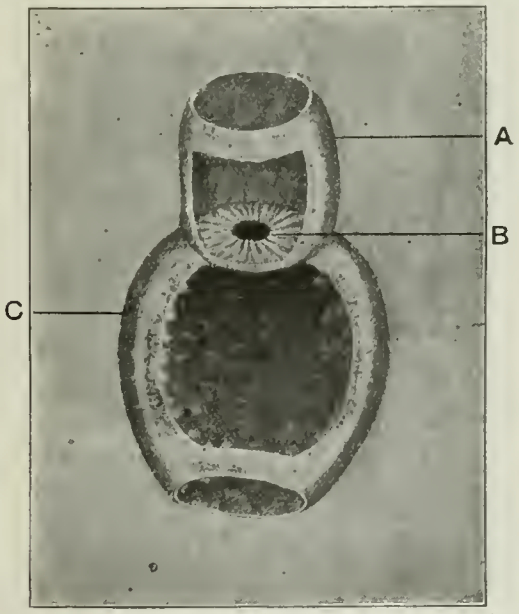

Fig. 8.—Ileocecal valve of a Conger eel. A, ileum; B, ileocolic valve; C, colon (Huntington).

medical periodicals[13] during the past two years.

The accompanying radiograph (Fig. 12), made by Dr. Case, shows incompetency of the valve, permitting the injected bismuth solution to pass into the small intestine for many feet.

As regards the causes which produce incompetency of the valve, Kraus holds that the principal cause is the breaking (Fig. 14) or stretching (Fig. 15) of the habenula. Stretching or rupture of the habenula may be caused by overdistention of the

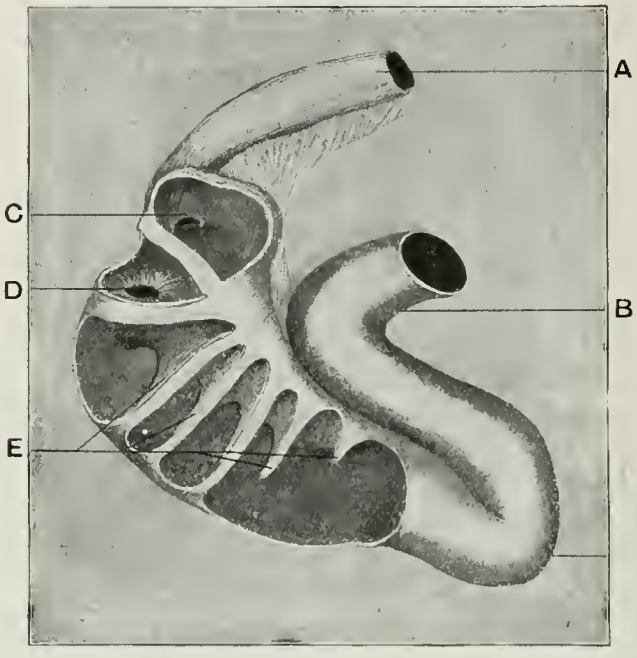

Fig. 9.—Ileocecal valve of a South American lizard (Huntington). A, ileum; B, colon; C, ileocolic junction; D, secondary valve; E, spiral valve.

large gut. This may result either from constipation or from gas accumulation. By overdistention of the gut the ileocolic junction is subjected to such a severe strain that the folds which form the valve are straightened out (Figs. 16 to 18). In other words, the small intestine is pulled out of the large gut. The normal intussusception is obliterated. The normal curve of the large gut upon itself disappears and in very pronounced cases the lumen of the small intestine at its junction with the colon becomes funnel-shape. This overstretching destroys both the mechanical structure of the valve by which reflux from the large into the small intestine is prevented, and also the sphincter which controls the movement of material from the small intestine into the colon.

It is probable that competency of the ileocecal valve may also be destroyed by distortion of the folds resulting from cicatricial contraction, caused by ulceration or inflammation.

The observations of Max Hertz convinced him that the valve may become incompetent through atrophy of its tissues, the natural result of chronic colitis, and the valve may be destroyed by tubercular disease.

Temporary incompetency may probably result from overdistention either by accumulation of gas or liquid contents or by the introduction of a large amount of water by enema (Cannon, Case). Dr. Case has observed that the valve may be rendered temporarily incompetent by the presence of a foreign body (a string in the case observed) in transit through the orifice.

When the ileocecal valve becomes wholly incompetent, numerous morbid conditions arise, among which are clearly demonstrable the following:

1. In complete incompetency of the ileocecal valve, the passage of a large amount of undigested material from the small intestine into the colon may cause irritation and diarrhea.

2. When the contents of the small intestine pass rapidly into the colon instead of being introduced in small successive quantities, the colon is overdistended, stasis occurs, putrefactive processes are encouraged, colitis, pericolitis, or appendicitis may result, and conditions are produced which prepare the way for the development of tuberculosis and cancer, pathological conditions which occur with special frequency in this part of the alimentary canal.

Stasis is a natural and a necessary consequence of incompetency of the ileocecal valve. The integrity of the valve is absolutely essential for positive movement of the intestinal contents in the forward direction. The sphincter at the ileocolic junction acts as a check valve which is essential at this point because of the special function of the cecum and ascending colon which requires retention of liquid material introduced from the small intestine to permit the absorption of water. The ingesta is held back and retained for a definite period at three points in the alimentary canal, at each of which it is subjected to special and essential processes, viz., (1) the stomach, in which it is held four or five hours by the pylorus for disintegration and preliminary digestion; (2) the terminal ileum, where it is held by the ileocecal sphincter for the completion of digestion and absorption; (3) the cecum, where it is retained for the absorption of water not by means of a valve but by reversed contractions of the colon—antiperistalsis.

Most authors agree that antiperistalsis does not exist in the small intestine, at least under normal conditions. For this reason the pylorus remains open when the stomach is empty without any evil effects resulting; but the powerful antiperistaltic movements of the colon necessitate the thorough protection of the ileum against reflux. When the ileocecal valve is incompetent, the contents of the cecum, instead of being churned and mixed, are forced back into the small intestine and thus the intestinal contents are prevented from advancing in the normal way, but are held in the cecum and terminal ileum.

Absorption is going on in the meantime, and the consistency of the intestinal contents is increased to an abnormal degree, so that advancement be-

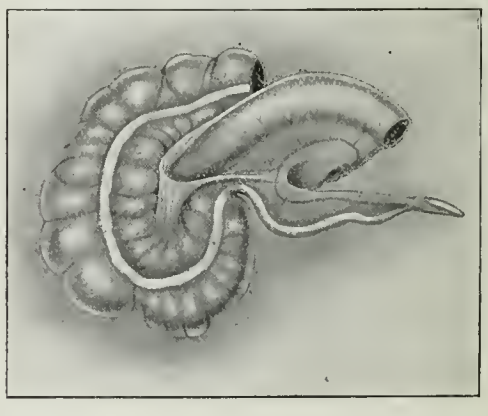

Fig. 10.—Ileocolic junction in chimpanzee (redrawn from Huntington).

comes still more difficult. The writer, in operating upon the intestine, has in several cases found the small intestine half filled with fecal matter of the consistency of putty, and at points several feet above the ileocecal valve.

3. The drag of this accumulated material upon the root of the mesentery, first pointed out by the late Dr. Byron Robinson of Chicago,[14] produces obstruction at the junction of the duodenum and jejunum, and so causes duodenal and gastric stasis.

Fig. 11.—Radiograph of cecum and ascending colon showing stasis due to excessive antiperistalsis in a case of colitis in the descending colon (Case).

Cannon has demonstrated that dilatation of the duodenum causes closure of the pylorus and thus produces stasis in the stomach.[8] The natural consequence of stasis in these parts as in every other part of the alimentary canal, is the abnormal development of bacteria and toxins with infection of the mucous membrane; hence result gastritis, duodenitis, gastric, and duodenal ulcer, cholecystitis, cholangitis, gallstones, pancreatitis, adhesions about the pylorus and the duodenum with chronic pain in the pyloric region, and various other morbid conditions connected with the stomach and digestion.

4. Appendicitis and the various troubles attributed to adhesions about the ileocecal region are a natural, almost necessary consequence of incompetency of the ileocecal valve. A diseased condition of the appendix was found in 63 per cent. of the 60 cases studied, and either Lane's kink or appendicitis was found in 77 per cent. of the cases.

Whether Lane's kink is the result of evolutionary processes as held by Lane or of embryonic origin as Flint[15] contends with so much convincing evidence, it is clear that the stasis produced by incompetency of the ileocolic valve in the cecum and the terminal ileum must tend to exaggerate the evils resulting from this condition.

5. Incompetency of the ileocecal valve interferes with the movement of gases even more than with the movement of liquid material. Liquid as well as solid material may be moved along in the large intestine even though the lumen of the gut is not completely closed during a contraction. Peristalsis in the colon differs from peristalsis in the small intestine. In the latter, contraction rings traverse the whole gut in such a way as to produce a positive forward movement of the entire contents of the intestine, both liquid and gaseous. Material is passed from the cecum upward through the ascending colon by shortening and mass contraction which is made possible by the fixation of the gut at the hepatic flexure. (Max Herz.) With a closed ileocecal valve, the contents of the cecum and ascending colon must move forward toward the transverse colon when the capacity of the gut is lessened by contraction; but when the valve is incompetent, although the forward movement of both liquid and solid material is still possible, though retarded, the intestinal gases are controlled scarcely at all. As the large intestine contracts, the gases rush back through the ileocecal valve, distending the small intestine, and so oscillate back and forth between the large and small intestine making little or no forward movement. It is on this account that patients in whom the ileocecal valve is wholly incompetent are usually subject to a most distressing accumulation of gas in the intestine. The abdomen is greatly distended, and while small quantities of gas escape from time to time by mouth and anus, complete relief is never obtained. This form of flatulence is quite characteristic of complete incompetency of the ileocecal valve and was observed in 35 per cent. of the cases studied. When the ileocolic valve is incompetent, the bowel is practically unable to deal with gaseous material.

6. Constipation is another of the consequences of incompetency of the ileocolic valve. The valve is rendered incompetent by distention of the cecum and ascending colon which may be due to the accumulation of liquid or solid material but is most commonly produced by the development of an excessive amount of gas through the putrefaction and fermentation of retained fecal matters; but incompetency of the ileocecal valve may also cause constipation or at least greatly aggravate this condition by interfering with the forward movement of the intestinal contents. The result of this delay is the absorption of an excessive amount of water so the intestinal contents become almost or quite solid in consistency. The lower ileum and cecum being adapted to the handling of limpid liquid matters are not prepared

Fig. 12.—Radiograph after bismuth injection of the colon showing many feet of ileum filled with bismuth through incompetency of the ileocecal valve (Case).

to deal with this heavy, adhesive material and so the feces stagnate in the lower ileum and cecum, and are only slowly moved along the colon and when finally discharged resemble the feces of sheep.

Such fecal masses may often be felt in the cecum by external examination, usually giving to the examining fingers the impression of a mass of putty, although the consistency may be lesser or greater, according to the length of the delay. In these cases

Fig. 13.—Incompetent ileocecal valve.

x-ray examination may show retention of bismuth for several days in the cecum or even in the small intestine. The appendix is often visible,[12] the protective valve at its mouth having been forced open by the undue stretching of the gut. This patency of the appendix is a natural accompaniment of incompetency of the ileocecal valve, being produced by the same causes. This condition was found in 19 (32 per cent.) of the 60 cases studied in connection with this paper.

7. Incompetency of the ileocecal valve gives rise to conditions which may well lead to the highest degrees of intestinal intoxication. Schmidt has pointed out[9] that there is normally no putrefaction in the small intestine, putrefactive processes being confined wholly to the colon and normally prevented from extending into the small intestine by the ileocecal valve. When the valve is incompetent, putrefactive processes may extend not only by continuity but by reflux of the putrefying material from the colon into the small intestine. Schmidt has shown that the absorption of indican and other products of putrefaction is far greater when putrefaction occurs in the small intestine than when this condition exists only in the colon. The small intestine is evidently not so well prepared as the colon to defend the body against the attacks of putrefactive and toxin-producing bacteria. It is not surprising then that in cases of incompetency of the ileocolic valve we find most pronounced symptoms of autointoxication, the sallow, atrophic, pigmented skin, incipient and advanced arteriosclerosis, and other old age conditions occurring prematurely, with cardiovascular-renal disease, chronic rheumatism, neuritis, insomnia, and various groups of distressing symptoms to which the term neurasthenia is commonly applied.

In an analysis of the symptoms of 60 cases in which the ileocolic valve was shown by x-ray examination to be incompetent which have come under the observation of myself and my colleagues at the Battle Creek Sanitarium within the last few months (April, 1912, to January, 1913), the characteristic symptoms of intestinal stasis were found constantly present. In 87 per cent. of cases the patient complained of constipation. In eight cases (13 per cent.), the patient complained of too frequent bowel movements, a condition which was found to be due either to irritation arising from stasis or to the passage of undigested material into the colon. The following table gives the leading symptoms noted in these cases and the percentage of cases in which each symptom occurred as a prominent feature, omitting the various nervous or neurasthenic symptoms which in varying form and degree were noted in all:

| | Per Cent. | | Per Cent. |
|---|---|---|---|
| Constipation | 87 | Gastritis | 5 |
| Diarrhea | 13 | Colitis | 63 |
| Marked gastric pain | 35 | Hemorrhoids | 23 |
| Obstinate indigestion | 62 | Flatulence | 35 |
| Gastric ulcer | 15 | Enlarged liver | 20 |
| Ileal stasis | 43 | Hepatic insufficiency | 7 |
| Cecal stasis | 38 | Casts and albumin | 11 |
| Cecal dilatation | 31 | Pigmented skin | 28 |
| Ileal or cecal stasis or dilatation | 71 | Headache (migraine) | 45 |
| Adhesions about duodenum | 22 | Chronic rheumatism | 25 |
| Duodenal ulcer | 10 | Neuralgia or neuritis | 23 |
| Patent (visible) appendix | 32 | Bronchitis | 10 |
| Diseased appendix | 63 | Arteriosclerosis | 25 |
| Lane's kink | 33 | Mental and nervous depression | 45 |
| Obstruction in colon (adhesions, kinks) | 37 | Insomnia | 30 |
| | | Intestinal autointoxication | 100 |

A study of the grouping of typical symptoms is very interesting. Lane's kink was found associated with gastric, duodenal, or ileal stasis, or gastric ulcer, in 16 cases, or only 27 per cent.

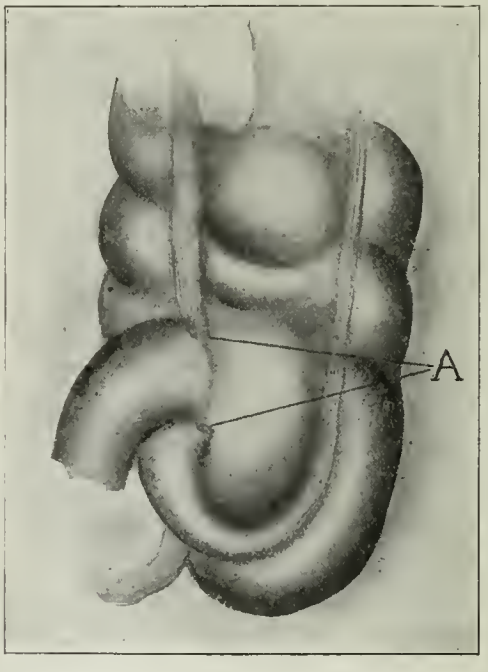

Fig. 14.—External appearance of ileocolic junction in case of incompetency of the ileocecal valve due to rupture of the habenula (See Fig. 6) (Redrawn from Kraus).

Lane's kink was absent in 27 cases in which gastric stasis, duodenal stasis, ileal stasis, or gastric ulcer was found, or 45 per cent. of the whole number of cases.

In 53 of the 60 cases, or 88 per cent., one or sev-

eral of the following conditions was found present: Gastric stasis, gastric ulcer, duodenal stasis, ileal stasis, adhesions about the pylorus or gall bladder, Lane's kink, enlargement of the liver, hepatic insufficiency, gastritis.

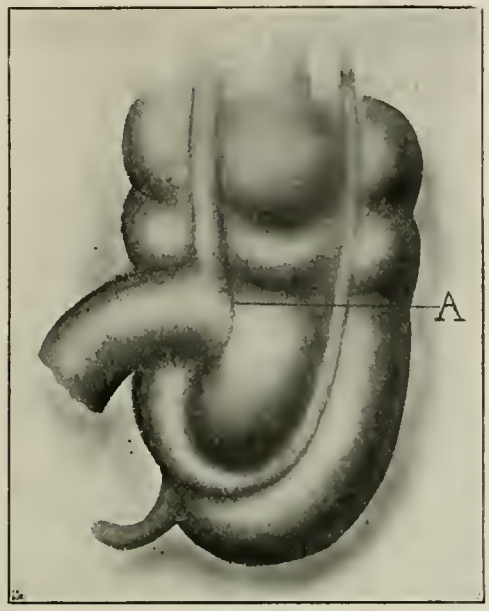

Fig. 15.—External appearance of the ileocecal junction with incompetency of the valve due to stretching of the habenula (redrawn from Kraus).

One or several of the following named conditions was found in each one of the 60 cases (100 per cent.): Gastric stasis, gastric ulcer, duodenal ulcer, duodenal stasis, ileal stasis, cecal stasis, dilated cecum hepatic or pyloric adhesions, Lane's kink, rheumatism, albumin or casts, migraine, gastritis, hepatic insufficiency, enlargement of the liver.

The small number of cases of diarrhea, only 13 per cent. (8) of the whole number of cases, is explained by the existence of colitis in a very large proportion of the cases. In these cases, the incompetency of the valve was evidently compensated by increased antiperistalsis. It is certainly evident that diarrhea is not a common symptom of incompetency of the ileocolic valve, as has been heretofore believed.

It is highly significant that one or several of the following symptoms appeared in 97 per cent. (58) of the cases: Gastric ulcer or stasis, duodenal ulcer or stasis, cecal stasis or dilatation, ileal stasis, Lane's kink.

From the above data it is evident that Lane's kink was not the determining cause of the various morbid conditions present. On the other hand, the constant association of incompetency of the ileocecal valve with gastric stasis, duodenal stasis, gastric and duodenal ulcer, ileal stasis, Lane's kink, intestinal intoxication, and other morbid states which arise out of the conditions named, must indicate either a causative relation or the existence of a common cause to which all these morbid conditions are due, including incompetency of the ileocecal valve. It must be conceded, at least, that incompetency of the ileocecal valve is a condition which must greatly intensify the evil effects of colonic stasis or whatever other condition may be the determining cause of such incompetency, and of intestinal intoxication.

*Palliative Treatment of Incompetency of the Ileocecal Valve.*—It is probable that in certain cases incompetency of the ileocecal valve may be a temporary condition due to acute overdistention of the colon and may be recovered from by the removal of the cause. In the great majority of cases, however, the condition must be regarded as a permanent disability which can be radically remedied only by a proper surgical procedure. Fortunately, however, the condition is one in which palliative measures may be applied with such success that the chief dangers and inconveniences arising from this disability may be completely overcome or to such a degree mitigated that they cease to be either a source of physical discomfort or a serious menace to health. Non-surgical measures which the writer has found especially efficient in these cases are the following:

*Increased Activity of the Bowels.*—It is the writer's belief that the bowels should move normally three times a day or after each meal. This is the rule with the peasantry of Turkey and Bulgaria, who live simple, active lives, as well as with the wild tribes of Africa, whose conditions and habits have not been perverted by an abnormal diet and a sedentary life. The keeper of the big apes of the London Zoo stated to the writer that the orangs and chimpanzees move the bowels four times a day. Whether or not so frequent bowel movement is essential for persons in ordinary health, it is certainly necessary for persons whose colons have been crippled and whose ileocecal valves are incompetent, in order to maintain sufficient activity in the stream of material passing through the intestinal canal to prevent stasis and the resulting putrefaction and other mischiefs which quickly develop when stagnation occurs in any part of the intestinal tract.

Three bowel movements a day are easily secured in many cases by the use of a bulky, laxative diet. In obstinate cases, agar-agar and paraffin oil should be used and will almost certinly secure the desired results. Even in extremely obstinate cases of constipation, electrical stimulation of the pelvic colon by means of a bipolar electrode applied through a proctoscope, massage of the colon, special gymnastics, improvement of the general health by out-of-door life, cold bathing, and other appropriate measures

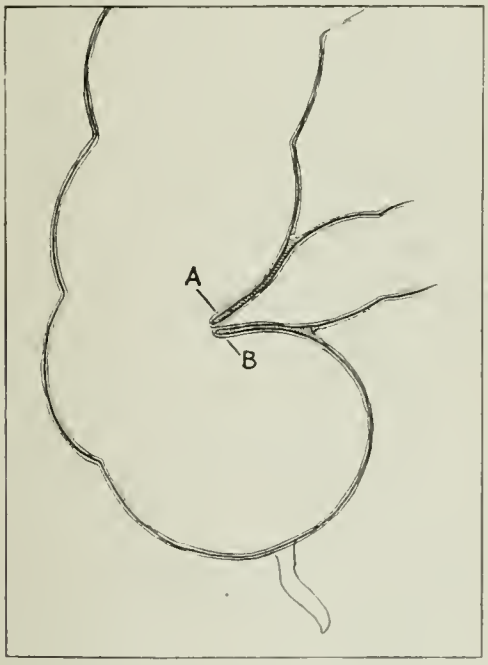

Fig. 16.—Diagram showing formation of the lips of the ileocecal valve by intussusception of the ileum.

faithfully and simultaneously applied rarely fail to secure the desired intestinal activity.

*Change of the Intestinal Flora.*—This is absolutely essential in these cases. While increased intestinal activity is first of all essential as a means of

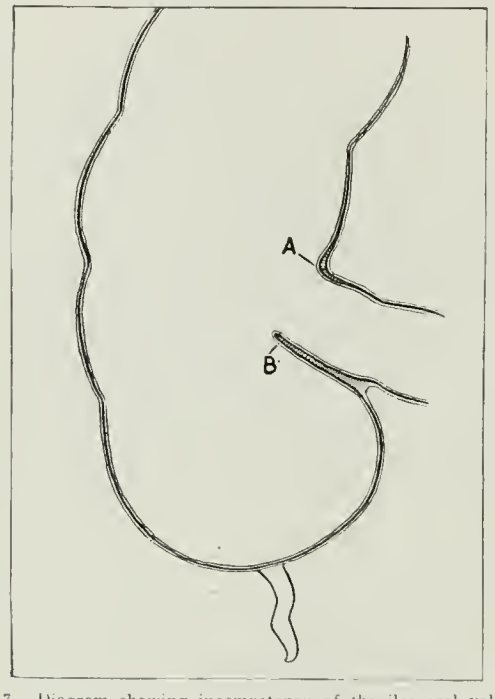

Fig. 17.—Diagram showing incompetency of the ileocecal valve due to destruction of one lip by overstretching of the gut.

lessening the opportunity for putrefactive changes in the intestine, the next important step is to change the intestinal flora. Putrefactive bacteria are the cause of intestinal infections and intoxications. These pernicious organisms can produce toxins only through the decomposition of nitrogenous matters or proteins. Hence the special necessity for a low protein diet in these cases. The Chittenden standard which makes the protein requirement 10 per cent. of the total ration, estimated in calories,[16] should not be exceeded. In many cases the proportion of protein may be for a time, at least, considerably reduced with great advantage. This practically requires the elimination of meats, at least of lean meats of all sorts. Tissier of the Pasteur Institute, who has perhaps devoted more time to the study of the intestinal bacteria than has any other bacteriologist, insists on the temporary exclusion of animal protein of all sorts, not excepting milk, having shown by extended researches[17] that animal protein undergoes putrefaction much more readily than does vegetable protein.

Besides limiting the protein to the actual body needs, it is essential that carbohydrates should be used very freely. Kendall has shown[18] that even proteolytic bacteria show preference for carbohydrates when these are present in available form, and that these mischief-making parasites actually become reformed in the presence of an abundance of carbohydrates, ceasing to form toxins and joining with the protective flora in the production of harmless and beneficent organic acids which not only prevent putrefaction in the intestine but render valuable service by furnishing to the intestine a normal stimulus, the lack of which, as shown by Schmidt and others, is one of the prime causes of constipation.

Acid forming ferments in the form of the *Bacillus bulgaricus* or liquid cultures prepared from bulgaricus and other lactic acid forming bacteria, may be used with advantage. The *B. bifidus* of Tissier[19] and the glucobacter of Wollman[20] are also useful. The writer employs a growing culture containing all three of these beneficent organisms. The *B. bulgaricus* forms lactic acid in the intestine. *B. bifidus,* a strict anaërobe, forms acetic acid in the colon. *B. glucabacter,* according to Wollman and Metchnikoff, converts starch into sugar in the colon and thereby encourages the growth of both *B. bulgaricus* and *B. bifidus* and also of other acid-forming bacteria which require for their sustenance sugar which is normally almost wholly absorbed in the small intestine, only two per cent. remaining to pass into the colon.

When ileal stasis exists, sugar must wholly disappear in the small gut, thus rendering impossible the development in the colon of the protective flora and encouraging the growth of the putrefactive organisms which always find in the mucus, bile, and other intestinal secretions as well as in undigested and unabsorbed food proteins always present in the feces, an abundance of protein which they decompose into indol, skatol, phenol, cresol, and various other putrefactive products which are the cause of intestinal intoxication and the bane of so many thousands of suffering mortals.

In the employment of the measures suggested and other allied means, the writer and his colleagues within the last year secured in the treatment of fifty-five of sixty cases of incompetency of the ileocecal valve who remained for treatment, the following results:

Thirty-six per cent. were very greatly improved, practically cured.

Fifty per cent. were improved and at last accounts still improving.

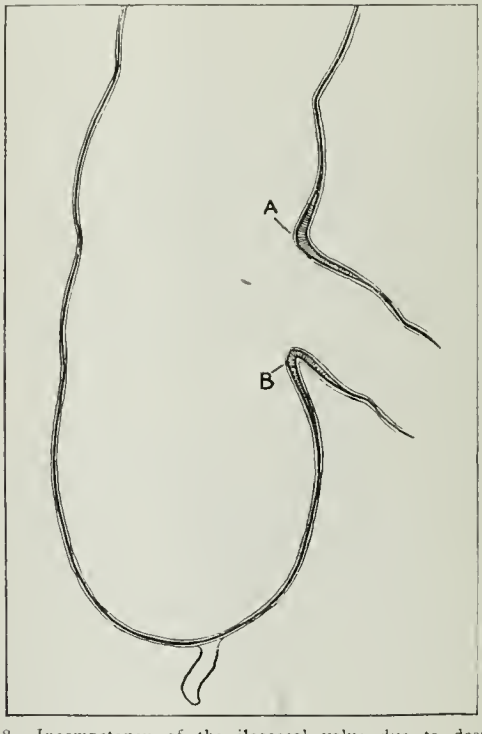

Fig. 18.—Incompetency of the ileocecal valve due to destruction of both lips, due to distortion of the gut.

Fourteen per cent. slightly improved, but needed longer treatment.

The average time of treatment was forty-eight days. The shortest period in any case was fourteen days, the longest one hundred and eighty days.

A very considerable improvement may properly be expected in every case in which the measures of treatment suggested are faithfully applied. As soon as the habit of moving the bowels three times a day is well established, the patient will note improvement, and as the intestinal putrefaction and intoxication diminish under the influence of an antitoxic diet and the use of antitoxic ferments, the various distressing symptoms from which the patient suffers will rapidly disappear. The skin becomes clearer, the pigmentation of face and hands diminishes in intensity and sometimes disappears entirely, the texture of the skin improves, dryness diminishes, and the skin becomes moist and more vascular and loses its parchment-like appearance. Indolacetic acid, indican, and other toxins disappear from the urine. In five of the fifty-five cases referred to in which casts and albumin were present, these evidences of renal disease disappeared. Headaches at first occur with less frequency and severity, and finally disappear. Depression of spirits and other neurasthenic symptoms vanish. The patient undergoes a general physical and mental regeneration which is most gratifying to witness and most delightful to experience, and which is ample compensation for the painstaking efforts put forth.

*The Radical Cure of Incompetency of the Ileocecal Valve by Surgical Procedure.*—The functions of the ileocecal valve when lost may be restored by a very simple procedure which consists simply in reconstructing the damaged habenula and reproducing the intussusception of the small intestine. With the abdomen open, the ileocolic junction is exposed, the bowel is turned outward so as to bring the under side to view and two sutures are inserted. The first is placed so as to restore the intussusception of the small intestine. The second is placed in such a manner as to restore the tension lost by the rupture or overstretching of the habenula. The appearance of the parts when the valve has been repaired is shown in Fig. 20. By a recent improvement in the technique of the operation a single suture is found sufficient in most cases. The suture picks up in succession each of the points which are to be approximated. When the suture is tied the four points are brought together and the desired effect is attained. It is easy to test the efficiency of the valve in both directions by stripping the contents of the small intestine into the colon then compressing the cecum, keeping always in view the small intestine which has been emptied. If the valve is incompetent, gas will be forced back into the small intestine with very slight pressure upon the cecum. If the application of a suture to one side does not completely remove the defect, a similar suture is applied on the opposite side of the ileocolic junction.

As regards the indications for the operation, I have never thought it proper to open the abdomen for the purpose of repairing an incompetent ileocecal valve, for the reason that the evils arising from this condition can be so efficiently and satisfactorily combated by means of an antitoxic regimen and the employment of other non-surgical means that surgical measures need not be considered. To date (June, 1913) the writer has repaired the incompetent ileocecal valve in thirty cases with excellent results. In each of these cases the abdomen was opened for the purpose of removing a diseased appendix or some other condition demanding surgical interference. It is quite possible, however, that cases may be found in which operation, especially for the purpose of repairing an incompetent ileocecal valve, is clearly justifiable. In these cases, other conditions needing attention are quite likely to be encountered when the abdomen is opened.

*An Artificial Ileocolic Valve Necessary in Ileosigmoidostomy.*—It is evident that if the evil results of stasis in the ileum or proximal colon are to be certainly and permanently relieved by ileosigmoidostomy either with or without removal of the proximal colon, reflux of feces into the small gut must be prevented by the construction of a new valve at the new ileocolic junction.

This the writer has done in ten cases. The first operation was done Sept. 1, 1912. The valve was proved to be competent by *x*-ray examination in each case. The technique of the operation is simple. It consists in so modifying the ordinary end to side method of anastomosis that the small intestine is intussuscepted into the colon about half an inch. A description of the technique of this operation will be given in another paper.

The remarkable results achieved by William Arbuthnot Lane of London, by removal or short circuiting of the colon are due to the elimination of the intoxication resulting from stasis in the colon and ileum. While this stasis may be in many cases due to a "kink" of the terminal ileum, the writer is certain that marked stasis is present in not a few cases in which no kink exists. Some of the cases reported by Lane and by Jordan, the distinguished roentgenologist of Guy's Hospital, clearly prove this as well as numerous observations by the writer and others at the operating table. In some of these cases the cause of stasis has been shown to be due to incompetency of the ileocecal valve. Incompetency of the valve naturally leads to abnormally quick emptying of the colon as well as of the small intestine but a study of sixty cases as above shown, demonstrates that this quick emptying is rarely observed. The reason is to be found in the coexistence with the incompetency of colitis, adhesions, "kinks," or other impediment to emptying of the colon. Under these conditions, antiperistalsis is greatly exaggerated.

Antiperistalsis thus becomes an active cause of aggravation of the evil results of the incompetency through a reversal of the normal forward movement of the intestinal contents.

Removal of the proximal colon eliminates antiperistalsis and this fact is probably the chief factor in the benefit derived from this operation for which the world is indebted to the courage and the genius of Mr. Lane; but reflux into the intestine after colectomy or short circuiting is not necessarily prevented unless the new ileocolic junction is protected by an artificial valve. If the new ileocolic junction is unprotected, neglect to keep the colon empty may result in a mechanical backing up into the small intestine which has been known to occur to such an extent as to distend the small intestine to almost the size of the normal colon.

In conclusion the writer ventures to express the opinion that the great importance of the ileocecal valve which has been demonstrated by the observations of Cannon and by various roentgenologists will command for this structure and its functions a much greater amount of attention in the future than it has heretofore received. I desire also to express my obligations to Dr. J. T. Case, the roentgenologist of the Battle Creek Sanitarium, for a careful *x*-ray study of my operated cases both before and after operation with reference to the functioning of the ileocecal valve, and to my assistant, Dr. R. H. Harris, for carefully noting and recording the results in operated cases.

# A CLINICAL STUDY OF THE APPLICATION OF IMPROVED INTRAVESICAL OPERATIVE METHODS IN DIAGNOSIS AND THERAPY.*

By LEO BUERGER, M.D.,

NEW YORK.

ASSOCIATE GENITOURINARY SURGEON AND ASSOCIATE IN SURGICAL PATHOLOGY, MT. SINAI HOSPITAL; ATTENDING SURGEON, HAR MORIAH HOSPITAL

If we were asked to make a concise statement of the useful endovesical operative procedures that can be carried out through the modern cystoscope by means of special instruments, we should answer as follows: The extirpation of tumors; the excision of suspected pathological lesions; the crushing and removing of calculi; the removal of foreign bodies; the snaring of papillomata; the dilatation of ureters; the excision of ulcers for diagnosis and therapy; the exploratory or therapeutic incision of cysts; the synchronous catheterization of three ureters and the synchronous employment of three or more catheters, and the excision of portions of a ureteral orifice for the diagnosis of renal tuberculosis. The technique requisite for the successful execution of these measures has been simplified, on the one hand, by the development of the proper optical systems and mechanical features of the operating cystoscope, and, on the other hand, by the construction of special instruments.

*Technique of operative cystoscopy.*—In recent work in operative cystoscopy,[1] I have employed the simpler of the two models of the operating cystoscope proposed in previous publications. Experience has suggested the adoption of certain improvements in this instrument and has led to the development of changes in mechanical and optical construction to meet the exigencies of some of the difficult problems that are at times encountered in this work. The instrument resembles very closely the author's catheterizing cystoscope, except that its shape is somewhat oval, and its telescope is provided with but a single outlet for the introduction of instruments of large caliber. Although two sheaths, the convex with a lamp on the convex side of the beak, and the concave (Nitze type) are constructed, the concave type is the more useful and has a larger scope of application. In order to add to the strength of the deflecting mechanism and to keep the operating instruments properly directed against the lesions to be attacked, the telescope has been fitted with a fixation screw. Two optical systems, the right-angled and one which looks slightly forward, were adopted to suit the varying physical demands of operating, either near to the sphincter of the bladder, or farther in the interior. It was found that by a special method of introduction, instruments of considerable size could be made to enter the sheath of the cystoscope.

The general assembly of all the instruments is the same, there being a wire shank carrying the working end or jaws (Fig. 1), a spiral flexible cannula, and a handle (Fig. 2). In the case of a large jawed forceps, it is impossible to introduce the working end through the catheter outlet, and we must execute the following manipulations for introduction. The cannula, provided with a sterile rubber cap to prevent leakage (Fig. 2) is introduced through the catheter outlet. The working end and shank are now passed through the cannula as it lies in the telescope, the handle is attached and the jaws are closed and locked. The telescope carrying the forceps, whose working end projects somewhat beyond the lens prism (Fig. 3) is now inserted into the sheath, the jaws of the instrument entering in advance.

In seizing a foreign body or in ablating tissue, the closed forceps is deflected against the lesion (Fig. 4), the jaws are then opened and gradually closed as the beak of the cystoscope is made to approach the bladder wall. In this maneuver the whole instrument, as well as the shaft of the forceps, moves inward toward the lesion. This manipulation is necessary to compensate for the recession of the jaws as they are being closed. A new type of mechanism more recently constructed obviates the necessity of this somewhat disturbing "recession" of the jaws as they are being closed, and furthermore permits of work being carried out at close range (Fig. 5).

*Exploratory excision in suspected carcinoma of bladder or prostate.*—The following history well illustrates the method of removal of pieces of tumor tissue in suspected carcinoma of the bladder, and demonstrates too that the margins of the growth can be removed at the same sitting, so that the pa-

*Read before the Section on Genitourinary Surgery, New York Academy of Medicine, February 19, 1913.

thologist has ample and adequate tissue for microscopical examination. With the exercise of patience, two of the difficulties which have to be met in exploratory excision can usually be surmounted. These are copious bleeding and the

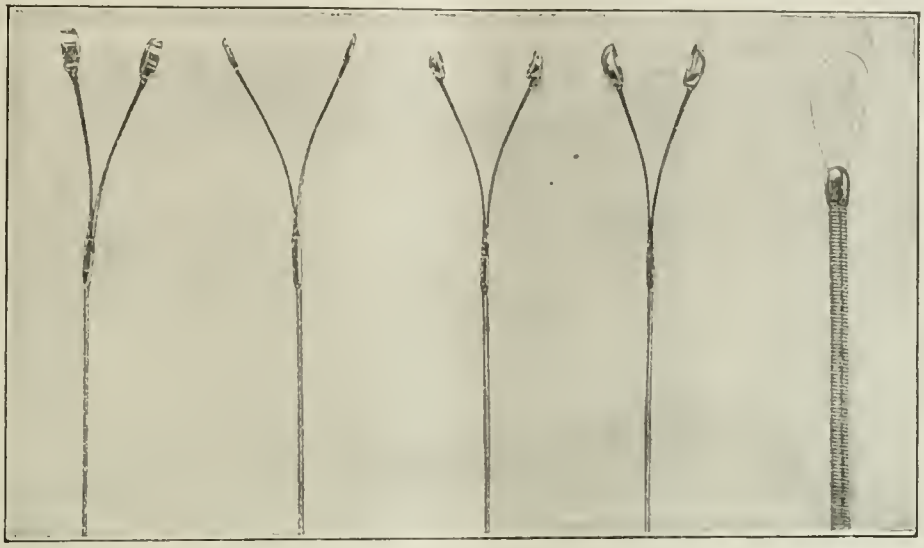

Fig. 1.—Working-ends of operating instruments; four forceps and a snare.

presence of large amounts of blood clot. When free coagula disturb the picture, these must first be washed out or be extracted with forceps. We then proceed to remove the clots attached to the tumor, to bring the ulcerating surface of the growth into view.

Case I.—E. R. H., admitted to the Genitourinary Service, Mt. Sinai Hospital, Nov. 11, 1912, had noticed blood for six months in his urine. Hematuria was most marked at the end of the act of urination, and lately pain on urination and burning has increased to such an extent that the patient consulted Dr. Goldenberg, who kindly

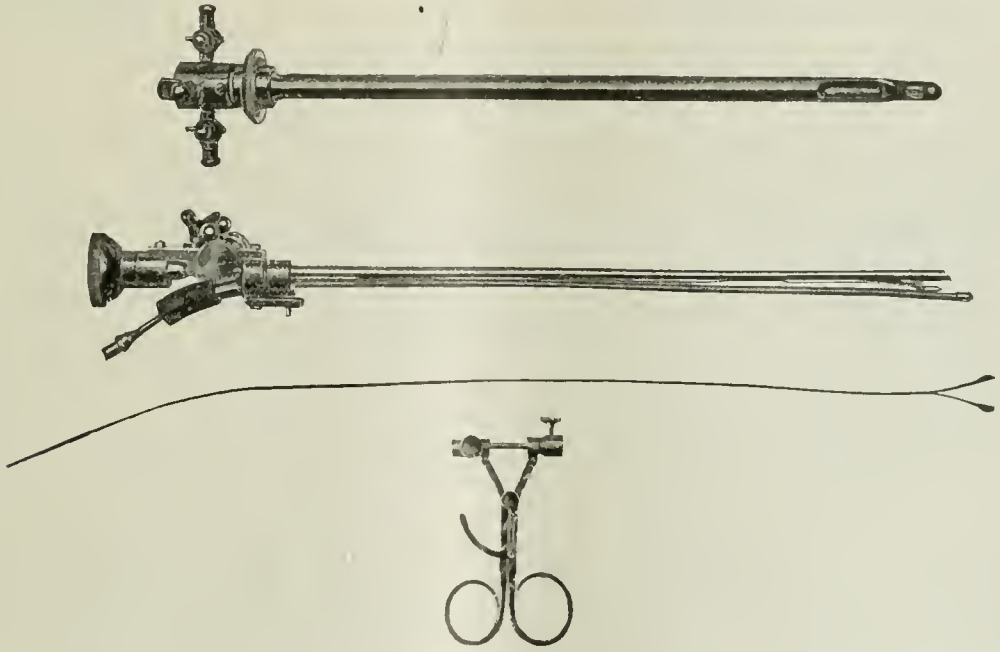

Fig. 2.—From above down, sheath of operating cystoscope, telescope with cannula adjusted; forceps, and handle.

referred him to the Genitourinary Service. On Nov. 13 and 19, cystoscopic examination was unsatisfactory, owing to large amount of free clot and coagula adhering to the tumor. On Nov. 23, after the surface clots were removed with the punch forceps, a sessile tumor was distinctly visible in the right infero-lateral wall of the bladder, not far removed from the sphincter. A broad stem, about 1.5 to 2 cm. in diameter, capped by a fungiform expansion of necrotic tissue and blood clots could be distinctly seen. A number of good pieces were excised with the punch forceps and sent to the laboratory for examination. On Nov. 27, cystocopy was again performed, and it was possible to remove a portion of the margin of the growth, including what appeared to be normal mucous membrane of the bladder. The microscopic sections clearly demonstrated (Nov. 23) the presence of a papillary carcinoma and the pieces removed on Nov. 27 showed submucous infiltration of the healthy wall, and invasion and destruction of the mucous membrane by the neoplasm.

An intravesical extension of prostatic carcinoma will often give a doubtful picture, it being necessary to make a differential diagnosis between primary vesical and primary prostatic neoplasm. The endovesical removal of pieces of such a tumor, followed by histological examination is of inestimable value in diagnosis.

Case II.—H. P., 63 years of age, admitted to the Genitourinary Service, Mt. Sinai Hospital, Oct. 14, 1912, with

hematuria, was found, on rectal examination to have a rather hard prostate, which made one suspicious of carcinoma. On Oct. 18, several pieces of the tumor, together with vesical mucous membrane at the margin of the mass were removed with the author's punch forceps and examined histologically. In Fig. 6 one of the sections illustrates clearly that we were dealing here with a type of carcinoma originating in the prostate gland.

*The excision of suspected vesical lesions.*—We are not infrequently confronted with alterations of the vesical mucous membrane whose exact nature is doubtful. Thus there are cases in which we find numerous tubercle-like eminences that arouse the suspicion of tuberculosis. These sometimes accompany a solitary simple ulcer of the bladder, at other times, are scattered throughout the vesical interior, and, in some instances, even have a definite relation to one or the other ureter.

Case III.—T. L., Russian, 34 years of age, admitted to the Genitourinary Service, Mt. Sinai Hospital, Oct. 25, 1912. He says that a year ago, the right kidney was removed for stone. For four years he has had cough and expectoration, and has lost 28 lbs. in the last six weeks. For a week there have been burning on urination and cloudy urine. He voids very frequently, every ten or fifteen minutes, and thinks that at times he has fever. Physical examination showed pulmonary signs suspicious of tuberculosis. On Oct. 28, 1912, cystoscopy was performed and revealed numerous tubercle-like lesions situated in the neighborhood of the right ureter, also behind the left ureter, and scattered here and there in the bas fond. Similar bodies were also found in the floor of the sphincter. These lesions were regarded as suspicious of tuberculosis, but owing to the absence of any ulcerating process and to the fact that the mucous membrane over these lesions was practically negative the possibility of follicular or lymphoid infiltration could not be ruled out. It seemed more than likely that a lymphoid type of inflammation was present. Therefore, on Nov. 1, the operating cystoscope was introduced and a small piece of the mucous membrane in the neighborhood of the right ureter, including several of the tubercle-like lesions, was removed with the punch forceps. Pathological examination of the specimen showed the absence of any evidence of tuberculosis, and demonstrated that an inflammatory process of the lymphoid type with the formation of lymph follicles under the mucus was present.

Then again, we encounter lesions that suggest vesical metastasis in cases in which we already suspect malignant change in a papilloma or in the prostate. Here the examination of excised vesical foci is of inestimable value. When a diagnosis in any case can be definitely made without causing traumatism of the bladder, it would be unwise to remove pieces for microscopic examination. There is a field, however, in properly selected cases, for comparative study of the gross endovesical appearances and the histopathological picture. Therefore, for purposes of research study, as well as for definite diagnosis, the excision of minute pieces of suspected lesions will doubtless prove valuable.

The following excerpt from one of my histories illustrates the value of removing for microscopic examination suspected foci in the wall of the bladder:

Case IV.—H. P., age 63, admitted to the Genitourinary Service of the Mt. Sinai Hospital Oct. 14, 1912, was found to have a hard prostate, which made one suspicious of carcinoma. Cystoscopic examination revealed a small tumor behind the sphincter on the left side, possibly an extension of a prostatic carcinoma. A small piece of this tumor was removed with the punch-forceps and the diagnosis—carcinoma of the prostate—made in the pathological laboratory. Far removed from this tumor, near the right ureter was a small polypoid excrescence which, on a second cystoscopic examination, had disappeared, leaving a minute ulcer about four millimeters in length. It was decided to remove this ulcer to determine whether a metastasis was situated at this point. The ulcer was removed without trouble by means of the forceps and histologically proved to be *metastatic carcinoma.*

*The removal of vesical calculi.*—Small vesical and ureteral calculi, if they are not too hard, may be crushed by a special miniature lithotrite (Fig. 7). When they are friable, they can be fragmented with the punch forceps, and the pieces can be easily removed with the cup-shaped jaws of the forceps. In the employment of this method of extracting small calculi, the bladder is not subjected to the deleterious effects of aspiration by the usual suction-type of apparatus. In my own experience such suction is invariably followed by intense hyperemia, and frequently by a mild grade of cystitis. By means of the small miniature lithotrite (Fig. 7), and the punch forceps, the removal of descended ureteral stone lying in the bladder becomes extremely easy. In the cases of larger or harder stones that cannot be crushed, the endovesical snare often serves as a reliable extractor.

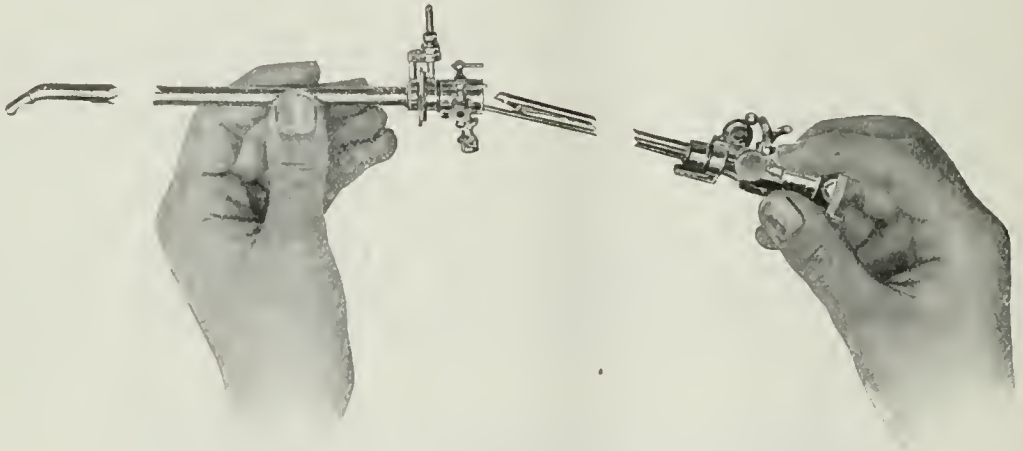

Fig. 3.—Method of introducing working-end in advance of telescope, through the sheath.

*The snaring of papillomata.*—Although the fulguration method is most satisfactory for the destruction of papillomata, experience has taught me that it is not only important to obtain adequate material for pathological examination in every case in which papilloma is suspected, but also that the endovesical operative destruction of these growths can be expedited by combining their surgical removal with cauterization of the bases or pedicles. In the case of small papillomata, the punch forceps introduced through the operating cystoscope suffices. Where we are dealing, however, with large papillomata,

we operate more rapidly and effectively with the old time-honored cold snare. In using the snare, we proceed as follows: The cannula of the snare is manipulated just as a ureteral catheter. The loop must be made ample, so as to easily surround the surface of the growth. The snare is then strongly deflected against the bladder wall. After the tumor has been encircled, we may avoid the recession of the loop by carrying both cystoscope and cannula inward in a compensatory fashion, as the wire is tightened around the pedicle of the growth.

Case V.—H. L., 56 years of age, was referred to me by Dr. K. Schlivek Dec. 10, 1912, because of persistent hematuria. The bleeding dated back nine months, although it was most severe during the past two months. Cystoscopic examination revealed two papillomata, a small one a little less than a centimeter in diameter, behind the right ureteral orifice, a larger tumor, about two and one-half centimeters in diameter, behind the left ureteral orifice. The general appearance of these tumors, their dendritic nature, and the likelihood of the presence of a pedicle determined me in attempting their removal with the endovesical snare. On Dec. 12, therefore, the operating cystoscope was introduced and both tumors removed with the endovesical snare. The left and larger tumor was removed in two pieces; the right one detached as a whole. Rather copious bleeding followed, although it ceased spontaneously after irrigation. As a final step, the bases of the tumor were fulgurated with the Oudin current.

The rapidity and effectiveness of this simple procedure, in this case, has led me to adopt it as a routine[3] measure. Further experience with this method will be described in a future publication. When suspicious mucous membrane at the base of the growth is left behind, this may be excised either at the primary or at the second sitting with the author's punch forceps.

*The dilating of ureters.*—When ureteral calculi are descending or in the cases of strictures, it is often advisable to bring about a certain amount of dilatation of the ureters. Although I have for a number of years practised dilatation of the lower end of the ureter, by means of the simultaneous insertion of two or more ureteral catheters into a ureter, followed by the use of bougies through the operating cystoscope, of late I have been employing graduated metal olives through which the d'Arsonval current is applied. Detachable metal olives are screwed on the end of an insulated wire electrode. These can be introduced into the lower end of the ureter, after the fashion of a ureteral catheter. With a large indifferent electrode over the symphysis or lower abdomen, the second pole being the metal olive, a current of 200 to 400 milliamperes is allowed to pass while gentle pressure is exerted against the point of ureteral obstruction. In many cases we will be surprised to see the obstruction give way after a few seconds' contact. The olive is then removed and a larger one inserted, the process being repeated until the ureter is dilated to 12-18 Fr. or more. This method has been found valuable in many cases where forcible dilatation with bougies has failed. In a number of cases of descending ureteral calculi, where this procedure was carried out, a small stone lodged in the lower part of the ureter was passed shortly after dilatation had been performed.

The following history is a good example of those in my series which show the beneficial effect of dilating the ureter in cases of descending ureteral calculus.

Case VI.—D. K., 42 years of age, admitted to the Genitourinary Service of the Mt. Sinai Hospital, Nov. 6, 1912, complained of having had a severe attack of pain in the left loin, five days before admission. His physician had found blood in the urine and had to give a hypodermic injection of morphine to relieve his distress. (In short, a typical attack of uteral colic.) On Nov. 8, cystoscopy was done, and the ureteral catheter encountered an obstruction in the left ureter about 4-5 cm. from its ostium in the bladder. Although there was no urinary flow when the catheter was first inserted, a sudden gush of slightly cloudy urine occurred when the catheter was pushed against the obstruction. About 10 c.c. were collected in a very few minutes, indicating retention of urine above the obstacle, possibly hydroureter. Oil was injected beyond the stone. *X*-ray examination showed a small shadow at a point corresponding to the obstacle in the path of the left ureter. In view of the findings gained at the first cystoscopic examination, viz., hydroureter and obstruction to the ureteral catheter, and because the oil injection had apparently been of no avail it was decided to dilate the ureter at a second cystoscopy. On Nov. 15, the ureter was dilated by means of the olives and the d'Arsonval current. As a preliminary step, three catheters were inserted into the ureter, two being No. 6 Fr. in diameter, the third being No. 5 Fr. Although the first catheter could be passed as far as the obstacle in the ureter (at 4-5 cm.) the second catheter advanced only 3 cm. and the third entered but a scant centimeter. It therefore became evident that very little could be accomplished by means of the ureteral catheters alone, and after preliminary injection of oil, the olivary method of electric dilatation was begun. Within a few minutes it was possible to dilate the ureter at the site of the stone to 14 Fr. and after this, a No. 9 catheter was inserted into the ureter, a very copious flow of urine being obtained. Four days later the patient returned having spontaneously passed a stone about the size of a small French pea.

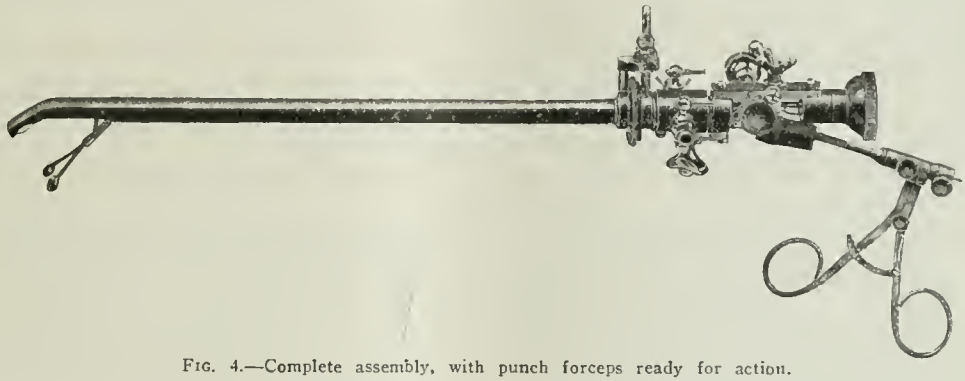

Fig. 4.—Complete assembly, with punch forceps ready for action.

*The excison of ulcers.*—A most remarkable cure following the excision of a callous ulcer of the bladder suggests the value of this procedure, not only in diagnosis, but also in therapy. The observation concerned a woman who had had a solitary ulcer for many months with marked dysuria, urgency of micturition, and who was cured after the ulcer had been excised for purposes of diagnosis.

Case VII.—E. H., female, was operated on by Dr. Lilienthal for left renal tuberculosis and the kidney was removed. For a long time, the usual vesical symptoms persisted, because of the presence of vesical ulceration. These were treated successfully by Dr. Lilienthal with the fulguration method, but an ulceration of the trigone at

the orifice of the ureter persistently remained. Although the bladder appeared to be free from other lesions, the symptoms were severe, there being marked tenesmus, nocturnal micturition, purulent and sanguinous urine and a refractory ulcer. During the months of August and September, 1912, numerous attempts were made to induce cicatrization of the vesical ulceration by the fulguration method. The ulcer was surrounded by a zone of hyperemic swollen mucous membrane, and surmounted by a large necrotic exudate more than a centimeter in diameter. On Oct. 28, 1912, it was finally decided to remove the ulcer with the punch forceps in order to determine whether we were dealing with a tuberculous lesion. Microscopic section revealed only evidences of a chronic inflammatory process with necrosis, absence of mucous membrane, and without signs of tuberculosis. On Nov. 4 the symptoms had abated considerably, the affected area showing a distinct tendency to heal. Two weeks after the excision (Nov. 11) the patient reported herself practically "cured" and the mucous membrane was found to have completely regenerated in the fashion so typical of healed vesical ulceration

More recently another case of simple callous ulcer was treated and cured in the same way.

*The exploratory and therapeutic incision of cysts.*—In rare instances we are called upon to puncture cysts or cystic formation in the bladder interior for therapeutic and diagnostic purposes. The presence of fluid content can be detected if the cystic lesion be punctured with a special endovesical knife. This simple instrument consists of a lance blade or scalpel fitted at the end of a flexible wire or spiral handle and is manipulated in very much the same way as a ureteral catheter. It was found useful in puncturing a case of closed ureter, with ureterocele, and may also be found of value as a preliminary step when a ureter that is to be dilated has an abnormally small orifice.

The utility of a cutting instrument for intravesical work was well demonstrated recently in the following rare and rather remarkable case:

Case VIII.—M. D., admitted to the Genitourinary Service of the Mt. Sinai Hospital Nov. 8, 1912, was examined with the cystoscope and the diagnosis of ureterocele (Fig. 8) was made. On Nov. 18, the operating cystoscope was introduced and the pyriform cystic mass which was situated at the site of the left ureter, and which was about the size of a small cherry, was punctured in four or five places with the endovesical knife. After several punctures had been made, the cystic mass completely collapsed and the ureteral orifice which had been previously discerned lying at the summit was found wide open and gaping. Although the mere puncture of this mass did not suffice to produce permanent collapse, the value of a cutting instrument as an aid to diagnosis, was here well demonstrated.

Experience has taught me that the endovesical knife will not always suffice to cut the mucous membrane of the vesical interior because of the elasticity

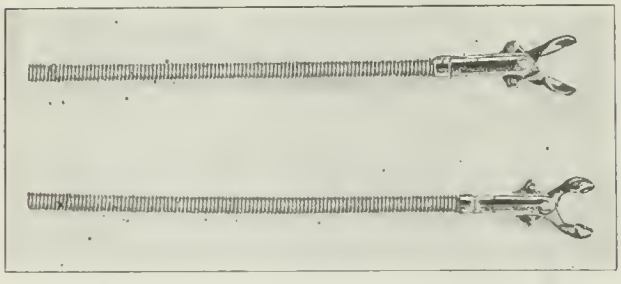

Fig. 5.—New type of cutting and punch forceps in which "recession" is obviated.

and toughness of this membrane. It was therefore found expedient to construct a scissor-forceps which is practically of value in incising the upper ureteral wall whenever it is deemed wise to do ureteral meatotomy before proceeding to dilatation.

*The synchronous employment of three or more instruments.*—Since the operating cystoscope is provided with but a single catheter-outlet and no catheter grooves or beds, it is possible to introduce into the catheterizing telescope more than two catheters.

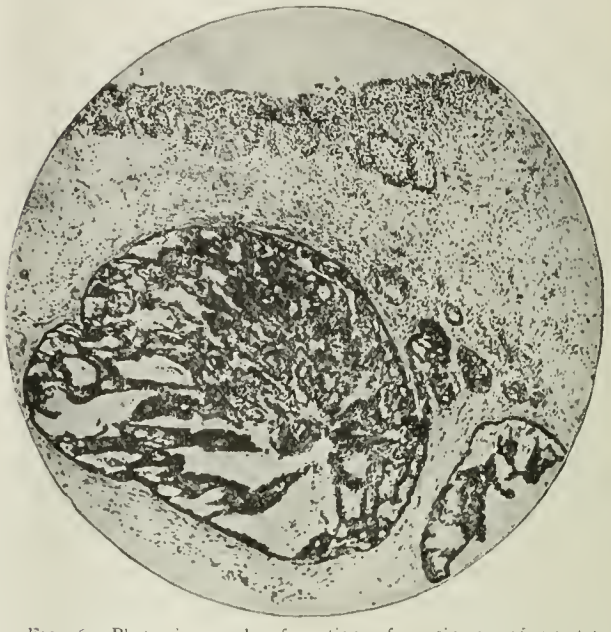

Fig. 6.—Photomicrograph of section of carcinoma of prostate-tissue removed through operating cystoscope; above, intact mucous membrane; in the depths, prostatic type of carcinoma.

By varying the shape of the sheath somewhat (making it somewhat oval) and by enlarging the conical setting at the ocular end of the telescope, we have been able to increase the capacity of this instrument appreciably. Thus two No. 6 Fr. ureteral catheters and a No. 5 catheter can be simultaneouly introduced and employed, there being sufficient room for easy manipulation as well as for irrigation. With increasing experience in cystoscopic work, and with a desire to accomplish more than a mere observation of the interior and mere catheterization of the ureters, there will often arise the occasion for the simultaneous employment of three or more flexible instruments. Thus not infrequently we meet with the following circumstances: One catheter has already been introduced and the urine of the corresponding side is being collected. An obstruction is encountered in the second ureter, and it becomes desirable to explore the obstacle with two catheters, or even to introduce two or more filiforms with a view to overcoming the obstruction.

In pyeloradiography the following condition will not infrequently call for the use of several catheters: One catheter has already been introduced, preparations for the injections of argyrol or collargol on that side having been completed. The other ureteral orifice appears large enough, but the catheter meets with an obstruction lower down. Reflux of the injected argyrol or collargol may in such instances be prevented if a third or a third and fourth catheter be inserted into the ureteral orifice to serve as a plug. This maneuver has been of value to me in many cases where I feared that the argyrol would not find its way into the kidney whose pelvis and ureter were being studied. Even in cases in which pyeloradiography is only called for on one side, such plugging of the ureter may be necessary. When the ureteral orifice is very large, then a second and third catheter will be found useful. Where three ureteral orifices are present in the bladder, or in cases in which there are only two orifices, but where

one ureter takes two catheters, the advantage of being able to employ three catheters simultaneously will be easily appreciated.

Recently in a case of coincident unilateral hydro- and pyonephrosis, where two ureters emptied separately on one side, a third ureter being present on the other side, the utility of triple catheterization was well demonstrated. In another interesting case of ureterocele, where after operative work with the operating cystoscope, the closed ureteral orifice of the affected side was converted into a wide opening, the employment of several catheters was found valuable, not only for purposes of diagnosis, but for the injection of argyrol for the demonstration of the hydronephrosis of the affected side.

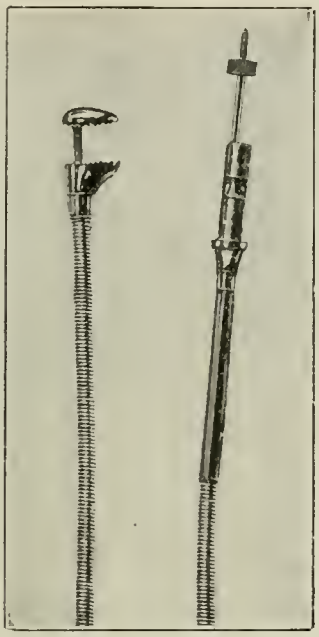

FIG. 7.—Miniature lithotrite; on the left working-end; on the right proximal end for adjustment of handle.

*The diagnosis of renal tuberculosis.*—In a preliminary communication[4] it was pointed out that in the absence of positive cystoscopic findings and in the absence of tubercle bacilli, a diagnosis of renal tuberculosis may often be made by finding miliary tubercles in mucous membrane excised from a suspected orifice, through the operating cystoscope. Since the writing of this paper a number of additional observations have been made, all of which tend to strengthen the view that this procedure is applicable in all cases in which vesical lesions exist and other corroborative findings are absent. Suspicious lesions such as rounded protuberances and edematous mucous membrane may involve a ureteral orifice or may be confined to the trigone or posterior wall of the bladder. From a study of six cases the conclusion seems to be warranted that edema of a ureteral orifice in a case of renal tuberculosis means the presence of miliary tubercles in the mucous membrane. The ureteral orifice may be free from visible change and the lesions may be behind or in front of it. If the latter contain miliary tubercles the diagnosis of renal tuberculosis may be made except in those rare instances in which a suspicion of an ascending process must be entertained.

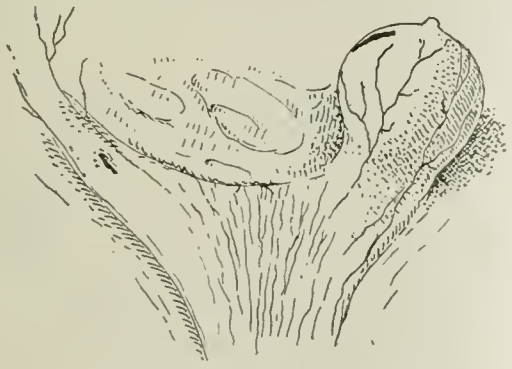

FIG. 8.—Ureterocele operated on by means of operating cystoscope.

## NEW INSTRUMENTS FOR THE DUODENUM AND SMALL INTESTINE.*

BY MAX EINHORN, M.D.,

NEW YORK.

PROFESSOR OF MEDICINE AT THE NEW YORK POSTGRADUATE MEDICAL SCHOOL.

DURING the years 1911-1913 I have devised the following instruments which I may be permitted to describe.

1. The duodenal obturator resembles in construction the pyloric dilator and aspirator (described in my book, "Diseases of the Stomach," fifth edition, p. 386), with the difference that the position of the dilating balloon and the aspirating or injecting arrangement is reversed. The balloon here lies at the end and the aspirating canal above. (Fig. 1.)

When the end of the instrument is way down in the duodenum, the balloon can be filled up with air to such a degree that the lumen of the duodenum is shut off. By injecting a fine bismuth and acacia mixture through the aspirating canal, the duodenum above the balloon becomes filled with the fluid up to the pylorus. An *x*-ray taken in this stage will show the shape of the duodenum. (Fig. 2.)

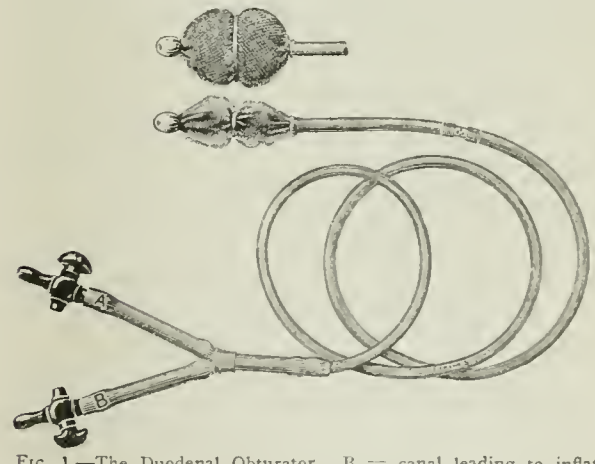

FIG. 1.—The Duodenal Obturator. B = canal leading to inflatable balloon. A = canal leading to aspirating or injecting arrangement.

*Demonstrated before the Medical Society of the County of New York on April 21, 1913.

2. The intestinal delineator is another instrument designed for *x*-ray work. It consists of a thin very flexible rubber tube (size 4 F) through which run two wires and a silk thread. At the end there is either a metal ball or a tiny

Fig. 2.—Shows radiograph of patient H. L., with duodenal obturator deep in the duodenum. The balloon was merely partly filled, so that the bismuth escaped by it into the lower portion of duodenum and beginning of the small intestine.

bucket. The apparatus is two meters long (Fig. 3.)

When the delineator is in the digestive tract the *x*-ray shows its position distinctly. If the end is deep in the small intestine the course of the duodenum and the small intestine can be mapped out. (Fig. 4.)

I am indebted to Dr. W. H. Stewart, radiologist of the German Hospital, for the above excellent *x*-ray pictures which he took for me.

3. The sectional Intestinal Examiner.*—This instrument (See Fig. 5) serves to examine a portion of the duodenum or the small intestine, with regard to its secretion and condition of its mucosa, walling off the juices from above or below. It consists of a three-canal tube (or one outer tube (size 15 F), containing two small caliber tubes) provided with two inflatable balloons between which are situated the end openings of the aspirating or injecting arrangement. The distal end of the instrument branches off into three separate tubes provided with stop-cocks and markings as to where their particular canal leads. (Fig. 5.)

The construction of this last instrument presented many mechanical difficulties which, however, have been successfully overcome. I am indebted for help in this respect to Mr. A. D. Scott and Mr. A. E. Pfarre, of Geo. Tiemann & Co.

Mode of Procedure.—The instrument (the remarks made here apply also to the other two instruments mentioned above) is best introduced about one hour before retiring, and care taken

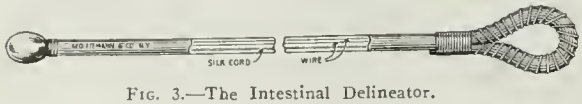

Fig. 3.—The Intestinal Delineator.

that it should go in beyond mark two. When arising the tube is inspected and if it is found that mark two is way in, a slight pull will show whether

*All three instruments can be obtained at Geo. Tiemann & Co.

there is resistance present. If so the probability is that the instrument has reached the duodenum. The middle or distal balloon is now inflated almost to its maximum and pulled up to the pylorus. Here it finds resistance and cannot pass. This makes it

Fig. 4.—X-ray picture of patient H. A., with intestinal delineator *in situ*. The course of the instrument in the stomach, duodenum, and part of the small intestine is distinctly visible.

certain that its position is in the duodenum. Then the end balloon is likewise inflated. A few cubic centimeters (5-10) of water are injected into the separated section of the duodenum. Wait five minutes, then aspirate. A juice is then obtained which originates in the duodenum. If the instrument is just in the position mentioned, the secretion will contain duodenal and pancreatic juices and bile, for the end balloon is just beyond Vater's papilla.

If it is desirable to have duodenal secretion without bile, this may be obtained by having the middle balloon beyond Vater's papilla, when the juice of the second half of the duodenum will be aspirated. Similarly the secretion of the first portion of the duodenum may be obtained by arranging the two balloons somewhat nearer each other, in such a manner that when the middle balloon is near the pylorus the end balloon is above Vater's papilla and not beyond it.

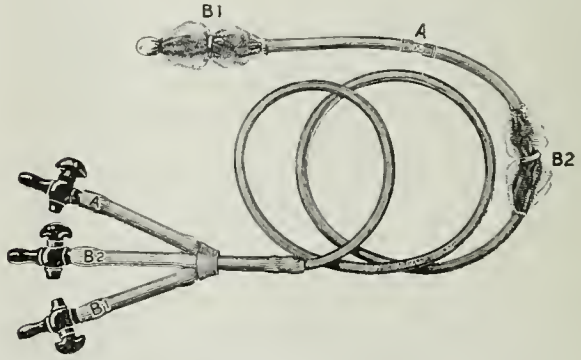

Fig. 5.—The Sectional Intestinal Examiner. A = canal leading to aspirating or injecting arrangement, ending in several small openings A. $B^1$ = canal leading to end balloon. $B^2$ = canal leading to middle balloon.

**Diphtheria of the Stomach.**—F. E. Tylecote concludes that this condition is commoner than appears from the literature. He distinguishes true diphtheria of the stomach, or *diphtherial* gastritis from a mere membranous or *diphtheritic* gastritis.—*British Journal of Children's Diseases.*

# A PARANOID STATE.*

By MARY KEYT ISHAM, M.D.,

COLUMBUS, OHIO.

The increasing interest in psychiatry continually adds to the number of those who puzzle over the difference between a paranoiac and a paranoid. A slavish study of Kraepelin and one good classical case of paranoia presented to us as contrasted with the typical paranoid form of dementia præcox will furnish us with very clear-cut notions as to the difference between the two. But when we pass from the servile study of one textbook on psychiatry to a more extended list of references and also advance into a close acquaintance with many patients of this class, we are confronted by numerous uncertainties and finally adopt the attitude of Dr. White who questions "whether we are not really dealing with two extremes between which every possible transitional form may be found."†

Dementia præcox is a psychosis essentially of the period of puberty and adolescence, characterized by a dementia tending to progress, though frequently interrupted by remissions (White). Although essentially a disease of early life it frequently develops after twenty-five years of age, especially in the paranoid form of which only 40 per cent. appear before the twenty-fifth year. This paranoid form is so called because it resembles paranoia and is principally differentiated from it by the presence of progressive dementia. The predominant element of the paranoiac character is the feeling of suspicion which finally develops into systematized delusions of persecution.

But there are other differences cited between the two, besides the progressive dementia. The principal features of paranoia, as distinguished from the paranoid form of dementia præox, are generally conceded to be the following: The onset is gradual with only a few hallucinations if any. The delusions of persecution or of grandeur are founded on real facts, which are wrongly interpreted, but develop into a coherent and plausible whole and can be most ingeniously explained by the patient. You often cannot tell whether his interesting statements are the truth, unless you know the facts. He appears to be a person of unusual active mentality, generally an entertaining talker—until you have met him several times and learn that you will hear the same old tale. He makes no fantastic statements in general conversation which immediately brand him as insane, neither does he show any gross tricks of gesture and manner. His behavior is almost normal and the emotional attitude is fairly uniform. He is able to occupy himself steadily. Consciousness is unclouded, thought is consistent, and there is absence of progressive dementia, at least until very late in life, when it comes on in the proper time of old age. The delusions never disappear entirely, but at times may be less active.

In the paranoid forms, on the other hand, the onset is comparatively acute, with insomnia, depression or a maniacal condition, loss of appetite, emaciation, etc. Numerous fleeting hallucinations are very prominent and fantastic changeable delusions quickly develop, but are only loosely organized into a system. Delusions of physical influence are very frequent and pronounced. The patient's emotional attitude is subject to frequent, sudden, and marked changes, and he exhibits peculiarities of behavior, such as mannerisms, tricks, negativism. He is flighty and unsteady in his work. His intellect is frequently clouded and there is a progressive dementia. Remissions may occur.

These distinctions sound clear and easy enough, but, as a matter of fact, a diagnosis is often very perplexing for several reasons.

In the first place, paranoids usually do not develop a pronounced disturbance until after twenty-five and their dementia may be very slowly progressive. You may have to wait until a patient is rather advanced in years before you can decide whether he is dementing or not.

In the second place, paranoids very frequently do not exhibit the tricks of manner which other forms of dementia præcox show. They are more self contained, more intelligent, more particular of appearance. Only at times do they break forth in peculiar mannerisms and then usually when fatigued or excited.

In the third place, whether a system of delusions appears fantastic or peculiar depends largely upon the way the observer may look at it. An idea may seem very unreasonable to a casual observer, but the physician who studies further may detect rationality when he becomes acquainted with all the circumstances leading to the patient's belief. Whether an idea is dubbed fantastic or peculiar depends much on the ability of the psychiatrist to fathom the associations.

And now to illustrate the difficulty of an exact diagnosis between the forms under discussion by the history of a case.

The patient was born December 17, 1864, in F————, Ill. She is the third child and first daughter of five children—two boys and three girls. The brothers are both dead. The first grew to adult life and was killed in a railroad accident. His wife and three children are healthy. The second brother died in infancy. The two sisters are living. There is nothing so far as known to indicate a defective nervous heredity except that the father's sister was insane and the patient and her sisters all suffer from periodic headaches. The mother died of apoplexy. The father, a physician of fine standing, died of toxemia from a carbuncle. The patient was graduated from the high school of her town at sixteen years of age. She then went to a denominational college in her native State and was graduated after a three-year course. She taught one year in a graded school of her town. Then she married in September, 1885, and went immediately to S————, in Ohio, to live. Her first child, a son, was born in January, 1889. She did her own work most of the time. When she told me this she sighed and explained that she was not radiantly happy after her marriage, that she felt timid and strange, extremely nervous and lonely, and was very slow at making friends in her new surroundings. She had met her husband only a few times before marriage and never felt really acquainted with him. He was a very Puritanical and ascetic nature, she said, while she had warm southern blood and a social disposition. The second child, a daughter, was born in July, 1891. A few years after this she had a miscarriage. A third child, daughter, was born in February, 1898. About this time she began to suffer from an inguinal hernia. She wore a truss for about a year, but was finally operated upon for this trouble by Dr. Harry Miller, of S————, in 1902. She stayed at the hospital for about two weeks, went home feeling splendid, and was well all summer. A sister who was staying with her at that time helped her with the house work. Her house was large and well kept. She was president of a missionary society, and belonged to two literary clubs. She was greatly respected and admired for her strong character, ability, culture, and social charm. But she was always under a great nervous strain and never felt at home.

Shortly after the hernia operation, the wife of her family physician remarked to her that the doctor thought a great deal of her—admired her. So many things were said to this effect that she thought something was in the wind.

*Read before the Columbus Academy of Medicine, March 10, 1913.

†"Outlines of Psychiatry," by Wm. A. White, M.D., p. 97. *Am. Jour. of Insanity*, July, 1912, p. 27.

She liked her family physician very much and said she was always glad to see him, and he evidently enjoyed her conversation. But being unduly sensitive about the matter, this patient called on his wife and told her that she had no friendship for her husband (the doctor) which could not be shared with her. About this time Dr. Lyman Abbot was publishing an article or series of articles in the *Outlook* in answer to the letter of a woman who had asked his advice in a domestic dilemma. She said she had found her husband was not true to her and she wished to know her Christian duty in regard to the matter. The patient read this correspondence and conceived the idea that the wife of her family physician had written the letter because she thought the doctor in love with said patient. This so troubled her that she told a friend about it and asked her what to do. The friend exclaimed, "Why Mrs. ————, you must be crazy!" To which the patient replied, "I sometimes think I am." She was in a constant state of terror as to what people were saying about her and doing. Her pride, extreme sensitiveness with timidity, and lack of congeniality in her surroundings, together with a critical and egotistical temperament, began to crystallize about these innocent remarks and definite suspicions developed.

It happened that the next winter she had pain and swelling on the same side as the former hernia, but higher up. After months of serious illness, an operation was deemed necessary. I shall quote from a reprint by Dr. Miller, who operated upon her. His paper, "A Case of Combined Extrauterine and Intrauterine Pregnancy," refers to this patient. Has always menstruated regularly until the fall of 1904, when there was a change in the menstruation, though it did not cease with the same regularity as in a normal pregnancy. The pain in the right side at times was quite noticeable. In the early part of November the abdomen in the region of the right iliac fossa became prominent. Though at times there were fainting attacks, there were never manifested symptoms of shock. In the latter part of January, 1905, menstruation ceased entirely, only to commence again in the latter part of February. The flow was irregular and there were present all the symptoms of an impending abortion. About the middle of March the patient was attacked with an acute localized peritonitis in the right iliac region. From the history of the case, learned from her attending physicians, this attack must have been a severe one. During the attack of peritonitis the distention of the abdomen and the pain were so severe that a careful examination could not be tolerated. However, a tumor could be detected in the region of the right ovary. At this period the patient drifted into other and not scientific hands, and while she had seemingly recovered from acute symptoms, she did not recover her former health; the abdomen remained prominent and she was always conscious of pain in the region of the right ovary.

"While I had operated on the patient for the strangulated hernia, I did not see her for the present trouble until about the fourth day of May. I found, upon examination, a tumor about the size of an infant's head, occupying the region of the right iliac fossa, and the uterus, considerably enlarged, crowded into the left iliac fossa. From this history it was the opinion that there existed an extrauterine pregnancy dating from some time in the autumn. This being the conclusion, and an operation being deemed imperative, the patient was removed to the hospital. On the ninth of May the abdomen was opened, and a cyst-like tumor, about the size of an infant's head, was found occupying the right iliac fossa, crowding the uterus over into the left iliac region. * * * * * * * * * The enlarged uterus excited a strong suspicion of there being an intrauterine pregnancy. The walls of the tumor were about an eighth of an inch in thickness; at its lower pole was found a mass composed of tissue resembling in every particular the placenta; the center of the mass measured, roughly, about half an inch in thickness, while at its periphery it was lost in the walls of the tumor. In the pedicle was found an organized blood-clot protruding into the cavity of the sac. The cavity of the sac was distended with dark-colored blood, in which were floating masses somewhat resembling broken-down tissue, probably the fetus having undergone retrograde changes.

"The patient left the operating room in excellent condition, the time for the operation consuming twenty-five minutes. She did well until the morning of the second day after the operation, when I received word from the interne that the patient was having a serious flooding and was suffering severe pains. Before I could reach the hospital she had been delivered of a perfectly formed fetus of about four months. This coincided with the cessation of the menstruation in the latter part of January."

After six weeks at the hospital the patient returned home. She was not able to do much that summer. She remarked with great sarcasm, "They claimed it was a tubal pregnancy." She said a report of it had been sent to all the doctors in S———— from pure malice. After the operation, she said, she did not suffer pain, but had weakness, confusion of mind, and frightful monthly hemorrhages. She thought that her friends treated her peculiarly and there was a spirit of ridicule and something in the air which she could not understand.

A day or so after the operation she saw from the window of her hospital room a dog which had passed through the operating room just before the operation. She recalled the fact that a negro—possibly an orderly or porter—had appeared in the anesthetic room. She did not think much about the dog and negro at the time, but later the memories and associations connected with this event worked dreadful havoc.

After leaving the hospital she had sensations of being pregnant and times of excessive flooding. She felt convinced that during the operation there had been an attempt to wreck her. She felt like a wounded animal under the pressure of adverse circumstances and by the following January had reached a place where she was completely at bay. She was physically ill and thought she was losing her mind. At this time her husband was away on a business trip. She felt imperative need of medical attention and wanted to go where she was not known. So she went to Columbus and took a room at a hotel. Dr. F. F. Lawrence was called in and after her son arrived, arrangements were made to take her to the Lawrence Hospital for curettage. She felt much better after this operation and the next spring took a trip to Washington, D. C., and Old Point and returned home in July. She enjoyed this trip very much and was particularly free from mental and physical worries.

But gradually the old worries came back with greater force. The conviction grew that something would develop bringing upon her an eternal curse. She had horrible sexual dreams at night. She was in great terror of being pregnant with pups or a negro, thought that the reproductive organs of the dog and the negro had been introduced into the uterus in some way, perhaps cut off and sewed up within it during the operation for tubal pregnancy—she did not know how—in order to satisfy some malice. She suspected that compromising pictures had been taken while she was under the anesthetic, that it was quite probable she had been infected with venereal diseases. She even thought that vicious suggestions had been made to her about her family physician. The system of persecution grew to such an extent that the sight of nearly every old acquaintance became unbearable. She refused to shake hands with her physician for fear he had some connection with the malicious plot. She nearly fainted when she met the surgeon who operated upon her.

Not only were all the physicians who had attended her implicated in the plot, but she accused some of the church members of leading immoral lives and being indirectly responsible. She feared that her children were being placed under hypnotic influence and would suffer from the same ideas. On this account, she tried to strangle her eldest daughter in order to protect her from future torture. Help was fortunately secured in time.

In November, 1907, she was taken to the Cincinnati Sanitarium and was discharged the following March as improved. After a visit with her sister in another State for several months, during which she exhibited many peculiarities of conduct, her family moved to Columbus, where they lived for over a year. The last six weeks of this time she spent at the Rodebaugh Sanitarium, where, in May, 1910, Dr. Lawrence did a hysterectomy for myoma of the uterus. She says that her physical health has steadily improved since this operation. A part of the next summer was spent at Wooster with her daughter, the two studying together at the university there. In August she found "they had been working up the insanity business," as she said, and were planning to place her in the Columbus State Hospital. In order to escape she clandestinely made rapid visits to Columbus, to Chicago, to Bloomington, back to Chicago, and then to Columbus.

This is a very long history previous to commitment, but I could hardly trace the development of the patient's delusions and show the gross physical troubles accompanying them without such a narrative. The physical disease no doubt determined the *character* of the delusions, but whether they caused the *formation* of a delusional system is very questionable. The origin of delusion formation most

probably lies purely in the mental constitution. Operations and physical treatment add to the patient's bodily comfort. But such nervous constitutional defects as the majority of insane patients show cannot be remedied by operations. It is true that she felt better after operation, but mental improvement was due to temporary fading of the delusions into the background because her attention was occupied with something new and exacting. These operations did not cure her mental disturbances.

The patient was admitted to this hospital on August 5, 1910, and was sent to Greer Cottage. She was then forty-five years old. Dr. Rowland made a provisional diagnosis of paranoia chiefly because her delusions were well systematized, she showed no signs of dementia, did not exhibit præcox tricks or mannerisms, and her conduct was uniform. After she had been transferred to one of my wards and had been observed for several months, I felt very greatly inclined toward the paranoid form of dementia præcox, because her system of delusions was extremely absurd and she was evidently dementing. At that period she grew more unreasonable in her demands, careless in dress, vacant in expression, and exhibited all the authorized symptoms indicative of dementia—"general dulling, memory weakening, disturbances of attention, impairment of judgment, lessened initiative, inability to concentrate the attention on matters formerly of interest, and a weakening of the normal affectivity."[2] At times she would make requests in a high pitched, unnatural voice in short, quick, choppy sentences, repeating them over and over. But later she regained her former neatness, dignity, intelligent interest in things, and general habits of culture; and when I learned more of her extreme ignorance of anatomical and physiological facts, her atrocious ideas about the possibilities of reproduction did not seem so absurd. Although rational and intelligent above the average on other subjects, no amount of reasoning or instruction could remove her conviction that the impossible feat of which she accused respectable, high-minded physicians, or that something equally fiendish, had been attempted. "I think that physicians would do anything to destroy a patient who tried to bring them to justice," she said. Note that she attributes this imaginary malicious act to vengeance for denunciations which she expressed after the operation was performed—a kind of retrospective falsification of memory.

During this period of improvement she was more like a paranoiac than a paranoid. But she also exhibited marked manic-depressive symptoms of variable intervals, and her relatives say that she has suffered from periods of excitement for many years. At times she suffers from an anxious depressed state lasting from several days to several weeks, and this often culminates in a sick headache, after which she is composed, rational, and appears normal and charming, then gradually her delusions work to the front and she is aggressive, excitable, unreasonable, domineering, and even violent. At such times she tries to run away and fights ferociously when detained—tearing the attendants' clothes, breaking their eyeglasses and using abusive language. From January to June, 1912, she increasingly improved and was granted unrestricted privilege of the grounds. She was then companionable and reasonable. I took long walks with her in which we discussed her delusions. She realized that we wished to help her and were not keeping her here through secret connection with her supposed persecutors. She even acknowledged that perhaps she had been temporarily insane and that certain ideas which she had always insisted upon were founded on facts might have been merely the result of malicious suggestions. Although during many years after the operation for ectopic pregnancy she had lived in constant terror of being or of becoming pregnant with pups as the result of what she thought happened at that time, she now no longer suffered this fear and acknowledged the unusual character of it; but, nevertheless, added shrewdly in support of her former claim that the fact that a certain thing had never happened was no proof at all that it never would happen. She could not be persuaded that the surgeon was entirely innocent, but thought he might not have appreciated the terrible result of what he did. Her delusions, however, did not appear to bother her. She would dig them up when I introduced the subject, discuss them good naturedly, and let them recede into the background of her thoughts, where they were apparently not disturbing her.

Her husband planned to move to Columbus away from her former unpleasant associations and take her out on a trial visit. But he kept postponing this move—for which no one can blame him—and one day, the patient grew tired of waiting and left us for home, first visiting a friend in Columbus on her way. The husband suggested allowing her to remain at home and later the family moved to Columbus. She kept house with the help of her daughter. The first few weeks she was somewhat depressed, but livable, but later grew more active and finally developed plans for a permanent home in Columbus. She wanted to take a house which her husband considered above his means. The patient's social ambitions as opposed to her husband's moderate means and naturally simple tastes had always been a source of contention and family unhappiness. In a hot discussion on this subject one night—several months after her trial visit—she became very violent in language and actions and struck her husband. He immediately telephoned for the sheriff and she was brought back to the institution about midnight. Since then, until very recently, she has made every effort to get away and we have been obliged to keep her in a back ward for safety. She has declared over and over again that every statement she ever made about doctors is absolutely true and she would use every effort to bring them to justice. She has also exhibited some præcox mannerisms, such as giggling and tripping around the nurses and repeating foolish, taunting things rapidly over and over. Her language once or twice has been profane and abusive, which is quite unlike her. At present she is improving again.

I very much suspect that her system of delusions has a Freudian origin in a submerged complex or psychic trauma of sexual origin. She had never, you remember, to use her own language, "been radiantly happy" with her husband. Perhaps the idea has already occurred to you that she had found an ideal in her family physician, but being a woman of exemplary conventional training, she would not admit this infatuation even to herself, much less acknowledge or show it to anyone else. Around this submerged emotion, I judge, she built a system of imaginary accusations from others, also persecutions, against which she struggled to protect herself by insane acts. Although aware that Freud would not attempt to use his method on such a chronic and marked case of insanity, I would like to see him push a psychanalysis to its conclusion with a patient of this sort. I have never dared to suggest to her what her original psychic sore spot might be, for the merest hint of such an emotion would make her furious and most probably involve the one suggesting it in her system of delusions.

There has been no attempt to present a complete psychanalysis of this case. Only enough of the patient's mental condition has been written up to justify asking you, what is the practical difference whether we call this a case of paranoia with manic-depressive symptoms, or a manic-depressive with paranoid delusions, or a dementia præcox of the paranoid type late in developing and very slow in dementing. The most pronounced fact about her mental trouble is her *paranoid state*. Much useless confusion has been avoided in several hospitals by classifying all these conditions resembling the classical paranoia as *paranoid states*. Of course, if a case presenting paranoid delusions very apparently belongs to some other classification as paresis, the toxic psychoses, those of the involution period, dementia præcox, manic depressive insanity, and some others, the most obvious diagnosis is the proper one. But it seems foolish not to make a diagnosis of these troublesome cases more easy by adopting the classification of *paranoid states*.

**Cholecystitis and Leucocytosis.**—Lutier and Salignat note that a leucocytosis of between 12,000 and 15,000 is one of the important symptoms of cholecystitis. There is also a polynucleosis similar to that associated with acute infectious processes.—*Gazette des Hopitaux.*

# A CASE OF GRAVES' DISEASE WITH SCLERODERMA AND A POSITIVE WASSERMANN REACTION, TREATED WITH SALVARSAN.*

By H. F. L. ZIEGEL, M.D.,

NEW YORK.

Mrs. J. A., 28 years of age, has had no serious previous illness except malaria in Italy when she was 9 years old. Her menstruation started at 13. At the age of 15 she married. Her first child died of meningitis in infancy. Her second child, a boy 7 years of age, is healthy; in him the Wassermann was negative one year ago. Her husband gives no history or clinical evidence of syphilis; in him the Wassermann was negative in 1911. Four years ago she again became pregnant but aborted at the second month. Since then her menstruation has been regular, moderate, painless, of three days' duration, and without marked molimina.

The patient first came under my observation in August, 1911. She had been nervous since a child, but no swelling in the neck had been noticed till Dr. Howard Fox, who four months previously had seen her at the Skin and Cancer Hospital, called her attention to this swelling. For two years previously (so she said in August, 1911) she had been more nervous and there had also been cardiac palpitation on exertion, visual disturbance, and difficulty in swallowing. Five months previously a lump was noticed on the external aspect of the left arm just beneath the shoulder. Later other hard areas appeared on the arm, behind the shoulder, on the anterior aspect of the elbow, and on the upper forearm. There was no pain, but occasional slight pruritus. She slept and ate well and did not feel weak. Defecation and urination were normal. The patient came complaining of the annoyance due to the hardness and discoloration of the skin, which had been increasing rapidly, also of "nervousness," headaches, visual disturbance, difficulty in swallowing, and cardiac palpitation on exertion.

Physical examination made in August, 1911 (some of the negative findings being omitted), showed considerable uniform swelling of the thyroid gland, moderate exophthalmos, presence of Graefe's and Moebius' signs, pulse frequency of 96° to 100°. No marked tremor. Extending from below the left cubital fossa upwards to the point of the shoulder, on the outer and front aspects of the left upper arm, and over the left scapula in the region of the spine, was a hardened condition of the skin, nodular in areas. The affected skin was discolored and furrowed, and in the central portions apparently longest involved it was slightly scaly. In some areas there was hard edema; here the skin could not be pinched up; it did not pit on pressure. Where most affected it was attached to the deeper tissues. The infiltration merged into the surrounding apparently normal skin. The color resembled somewhat that of ivory. There was no sclerodactylie, the skin of the lower forearm, hand, and fingers not being involved. The pupils reacted normally. Drs. Martin Cohen and Mulcahey made ophthalmoscopic examinations and found the fundus normal. There was slight general enlargement of the lymph nodes. The breasts were negative. The patient's weight was 149 pounds. The blood was negative as to anemia; the leucocytes numbered 9,000, with a slight relative increase of the mononuclear cells. The urine was negative.

August 18, 1911: the Noguchi modification of the Wassermann reaction performed at the Rockefeller Institute was positive. The Wassermann reaction performed by Dr. J. J. Hertz was positive. August 24: Salvarsan, 0.5 gram suspended in 3 c.c. of iodipin, was injected into the right sacrospinal muscle. On the following day the pain was slight at the site of injection, the pulse was 100, the rectal temperature was 100° F., and apparently no ill effects followed the treatment. August 29: Tumors of the skin softer. At the periphery of the areas where there is hard edema normal skin is replacing the hard patches. September 5: Further replacement by normal skin of sclerodermatous areas, especially those on the forearm and in the scapular region. Gaining in weight—now 150 pounds.

September 6, 1911: Repetition of salvarsan treatment; 0.5 gram of arsenobenzol in iodipin suspension injected into the left sacrospinal muscle. Though there was no constitutional reaction, the pain at the site of injection was very severe, and ever since then the patient has refused all injections. September 14: Further gain in weight, which is now 153½ pounds. The size of the thyroid gland has steadily diminished and the pulse has continuously become less rapid since the first salvarsan injection. To-day the pulse frequency is 80. The second injection of salvarsan was not immediately followed by marked changes in the skin condition as was the first treatment. The urine is negative. Arsenous acid, 1/30 grain, and sajodin, 5 grains, were started t.i.d. October 19: Wassermann negative (Dr. Hertz). The luetin test performed ten days ago is negative. November 20: Slow but steady replacement of hard patches by normal skin. The patient says she is much less nervous than formerly. The pulse rate is now 76. The thyroid swelling has diminished markedly since the salvarsan treatment. December 18, 1911: Further improvement in the skin condition. As to the nodules beneath the spine of the scapula, many have gone entirely and the remaining ones are softer and more movable. The forearm and cubital fossa are now entirely free of the skin lesions. The patient no longer complains of headaches and is less nervous. Pulse 76. Weight 156 pounds.

The patient unfortunately refuses an intravenous injection of salvarsan, also another intramuscular injection, though further salvarsan treatment was strongly urged. February 12, 1912: There has been little change during the past two months in the skin condition; it is now about one-third of its extent when first seen a year and a half ago; the tumors beneath the skin are not nearly as numerous as originally and those that remain are softer. Weight 160¾ pounds. Pulse 72. May 6, 1912: Continuous improvement in the general condition. Weight now 164 pounds. Pulse 72. The patient has been getting Fowler's solution, 10 minims, t.i.d. December 20, 1912: During the past seven months there has been no marked increase nor diminution in the extent of the morphea. Pulse 76. Arsenic internally continued, now in the form of the Dürckheimer Maxquelle water, 1 dram, t.i.d., p.c. April 1, 1913: There is noted some further improvement in the skin condition, which is now less than one-third of its extent when first seen by the writer. Bands

*Report read and case presented in the Section on Medicine, New York Academy of Medicine, May 20, 1913.

of normal skin are extending into the affected areas, causing the latter to appear as islands. Most of the nodules disappeared after the salvarsan injections one year and a half ago, and those that remain are softer and smaller than originally. The patient absolutely refuses any more injections. The weight is now 179 pounds, *i.e.* a gain of 30 pounds since salvarsan was first given. The pulse frequency is 68. There is now very little swelling of the thyroid. Since the salvarsan treatment there has been no recurrence of the headaches, "nervousness," cardiac palpitation, and difficulty in swallowing. April 7, 1913: The luetin test has again been negative. Dr. Howard Fox and the New York Board of Health found the Wassermann negative.

*Summary and Conclusions.*—In a married woman 28 years of age with Graves' disease complicated with the circumscribed form of scleroderma or morphea the Wassermann reaction was positive. There was no history or clinical evidence of syphilis. In a son 7 years of age and in the husband the Wassermann was negative. Since two intramuscular injections of salvarsan of 0.5 gram each were given one year and nine months ago the Wassermann has been negative; moreover, the treatment with arsenobenzol was followed by a gain of 30 pounds in weight, by considerable diminution in the thyroid swelling, by disappearance of the nervous symptoms and the tachycardia, and by marked improvement in the skin condition. Most of the nodules in the skin disappeared, those that remain are softer and smaller, and the scleroderma is now less than one-third of its extent when first seen; the skin on the upper forearm, in the cubital fossa and the scapular region, which regions were originally involved, is now apparently normal. Unfortunately there was considerable pain caused by the second intramuscular injection, and ever since then further treatment with salvarsan has been refused, though an intravenous injection was advised; instead arsenic in various forms has been given by mouth.

From an experience limited to one case it would surely not be justifiable to draw conclusions as to the therapeutic value of salvarsan in the conditions described. Moreover, a rational interpretation of the changes that have taken place would have to be based partly upon answers to the following questions: Did this patient possibly have latent syphilis, despite the absence of anamnestic and clinical evidence of the disease, and were the favorable changes and the negative Wassermann due to the antiluetic effect of the salvarsan? Did the arsenic have a direct remedial influence on the Graves' disease and the scleroderma? Or did the improvement occur spontaneously and coincidentally, *after* rather than *because* of the arsenic therapy? Certain it is, however, that the administration of salvarsan and other forms of arsenic was followed by negative Wassermann reactions, by marked improvement in the scleroderma and by symptomatic cure of the Graves' disease.

8 West Eighty-sixth Street.

## LOCAL AUTOGENOUS TEMPERATURE VARIATIONS, A CAUSE OF LABYRINTHINE VERTIGO.

PRELIMINARY REPORT.

By EDMUND PRINCE FOWLER, M.D.,

NEW YORK.

Sufficient heat or cold applied near the static labyrinth will produce vertigo and usualy nystagmus in definite directions depending upon the position of the head. The degree of vertigo, nystagmus, etc., varies with the sensitiveness of the organ and the amount and kind of tissue intervening between the labyrinth and the place of application of the heat or the cold.

The poor conductivity for heat of the tissues surrounding the labyrinth and of the blood and tissue currents, protects the semicircular canals and utricle from extreme temperature variations, and it is apparent that with the usual methods of applying heat or cold the temperature reaching the canals can be but a small fraction of a degree different from that already surrounding them. The bony labyrinth walls are only relatively good conductors of heat and their specific heat is low, but being surrounded by poorly conducting bone and tissues of high specific heat, it follows that they are quickly affected by changes in temperature and that such variations will persist near the area of application for appreciable periods of time.

The temperature of inflamed or congested tissue is never higher than the inner body temperatures, but near the surface of the body it is more elevated than surrounding uninflamed or non-congested tissues. Portions of the static labyrinth are near the surface of the body, and it follows that localized inflammations or congestion or anemias may bring about variations in temperatures and that these variations near the labyrinth will affect the flow of the endolymph, and if of sufficient intensity will cause vertigo and other similarly produced phenomena. Moreover, local relative heat or cold will cause hyper- or hypo-activity of the end organs.

This understanding of the cause of vertigo is in accord with my clinical observations. It also throws light upon many heretofore unexplained phenomena in otological practice and upon labyrinthine action in health and in disease.

I will fully report on this subject in the near future. At this time I wish simply to record my discovery.

616 Madison Avenue.

**Actinomycosis of the Liver in a Syphilitic Subject.**—H. D. Rolleston reports the case of a ragsorter, aged 29, who contracted syphilis eight years ago and had a fall on the right side one and a half years ago. About June 1, 1912, burning pain began in the hepatic region, and about June 10 he noticed a swelling in this situation. On admission there was a firm tumor measuring 3 in. by 2½ in. below the right costal arch, fixed so that it did not move with respiration. There were old scars on the face and neck and an enormous white serpiginous scar over the front of the chest. The spleen was not palpable. The urine contained albumin. The heart and lungs were normal. As the Wassermann reaction was strongly positive and he had irregular fever, the condition being thought to be gummatous, iodides were given. The tumor softened, and on being incised on June 30 gave exit to pus containing streptothrix mycelium. On July 18 the abscess was opened up and thoroughly scraped. Shortly after this operation there was a small hematemesis which contained actinomycotic granules. The patient, who is not very tolerant to iodides, has had various modifications of the latter, and has also had an autogenous streptothrix vaccine administered. The liver is much enlarged, and there are the scars of sinuses which from time to time discharge pus containing a Gram-positive streptothrix with well-developed clubs; some of the mycelium resemble streptococcic chains. The urine constantly contains albumin, the temperature is irregular, and the liver has tender spots.—*Proceedings of the Royal Society of Medicine.*

**Fulminating Secondary Hemothorax.**—G. Lardennois reports a case of gunshot wound of the lung in which at first the amount of hemorrhage was slight, but in which on the fifth day there occurred a rapid and fatal hemorrhage into the pleural cavity.—*Gazette des Hopitaux.*

## EDUCATION OF THE PUBLIC REGARDING THE CANCER MENACE.

THAT cancer is on the increase is a fact known in a general way by the medical profession, but whether this increase is real or only apparent is still a subject of debate. Mr. Frederick L. Hoffman, statistician of the Prudential Insurance Company of America, in an address on "The Menace of Cancer" delivered before the American Gynecological Society on May 7, gave interesting statistics on the prevalence of the disease. He said that the cancer question was without doubt entitled to serious consideration, not alone because of the terrible and insidious character of the disease, but because of the constantly increasing death rate, with a resulting heavy mortality in adult life. The approximate number of deaths per annum in the United States from cancer is 75,000, and for the civilized world about half a million.

Due allowance being made for possible inaccuracy of the statistical information on the mortality from cancer, there is sufficient evidence, Mr. Hoffman believes, that cancer is on the increase in the United States, though to a variable degree, according to age, sex, race, and locality. Of these, age is the most important factor, since cancer is relatively rare in early life, but quite common after the age of forty. The death rate from cancer increases slowly to the age of thirty-five, after which the rate increases rapidly to the end of life. It is higher throughout for women, on account of the mortality from cancer of the breast and organs of generation.

In 1910 there were 12,557 more deaths from cancer than from tuberculosis in the registration area, thereby showing the greater importance of cancer over tuberculosis, and the great need of education in the knowledge of the disease.

Cancer is apparently rare among the East Indians and also among our native Indians, and very little known among the Chinese, either here or in China. While the cancer death rates for different countries are not strictly comparable, such surprising differences have been shown that it seems safe to conclude that local conditions are in part responsible for the prevalence or absence of the disease. Switzerland, the Netherlands, and Norway show the highest rate; Jamaica, Servia, and Ceylon, the lowest; with the United States midway between them. Germany and Austria rank a little higher than the United States, and slightly lower than Ireland and New Zealand. It has been shown by the returns for the United States registration area that the mortality from cancer of the stomach and liver is about the same for men and women, with a higher rate among women for cancer of the rectum, intestines, and peritoneum, and a higher rate among men for cancer of the buccal cavity and skin. Excluding cancer of the generative organs and the breast, the death rate of the two sexes is about the same, the liability of women to cancer of the generative organs and breast accounting for the greater cancer death rate among women generally. Statistics also tend to show that cancer of these special organs is greater among married women and widows than among single women.

Regarding the theories of cancer, no trustworthy statistics have been obtained to substantiate the theory of heredity or the transmission from man to man; but a little more reliable evidence can be given to prove that certain occupations predispose to cancer. Also, making due allowance for differences depending upon age and sex, persons above the average in weight seem more predisposed to cancer than their thinner brethren. Finally, as regards the question whether statistical evidence of the increase in cancer can be relied upon, Mr. Hoffman believes that no mere improvement in diagnosis can explain the gradual rise in the cancer death rate in the American States and cities during the past thirty or forty years.

A special analysis of the combined statistics of American cities since 1870 further sustains the conclusion that the increase in cancer is real and not apparent. A similar increase has been observed in all civilized countries, showing that the liability to cancerous affections is greater at the present time than in the past. The menace of cancer is, therefore, real and not merely apparent, and of special interest to the adult population, especially those over forty years of age. Up to the present time the public have been in great ignorance concerning the treacherous and rapidly spreading results of cancer. It is now time they should be enlightened, while not being unduly frightened. Indeed, a nation-wide campaign of education would greatly reduce the mortality from this preventable disease, bringing enormous benefits to all mankind. Educational campaigns have been successful in Germany and other European cities, and they would be even more so in the United States. Toward this end the work of cancer research funds and intelligently conducted investigations would produce most useful results. In brief, cancer is a fearful menace to mankind, causing about 500,000 deaths per annum in the civilized world.

While early operation appears to offer the greatest hope of recovery at the present time, evidence is beginning to show that nonoperative treatment, even if not a certain cure, may offer at least material alleviation of pain and postponement of death for several years.

## SCARLATINA BENIGNA.

There is said to be a type of scarlatina so benign that it is not transmissible. It has gradually become the parent of the disease as we know it to-day. Another type entitled to this designation is inoculation scarlatina, as seen especially in Russia, and socalled symptomatic scarlatinas might also be classed here. But in the ordinary sense of the term, benign scarlatina is the commonest expression of scarlet fever in its ordinary endemic form, and while it is not the custom to separate the mild from the more severe types, it is a question as to whether such separation may not be justifiable.

At a recent meeting of the Basle Medical Society (*Deutsche medizinische Wochenschrift,* May 15) Wolter summed up all the scarlatina cases treated at the university clinic for a full year. The number was 241 and there were but three deaths (1.2 per cent.). The exact causes of death are not given and when we bear in mind the extreme youth of most patients such a record is practically clean. At the same clinic for the three years preceding 694 cases were treated with but 11 deaths (1.58 per cent.). The disease was so mild in degree that only symptomatic measures were required for treatment. The question which naturally asserts itself is why is it not desirable to speak of this expression of scarlatina as essentially benign because uncomplicated? The complications are in no wise characteristic of the disease, but may be seen in a number of other conditions. Why speak of three or more degrees of this affection? There is but little analogy or precedent for such a course, which means several degrees of virulence with disregard for complications. Folk scourge appears to belong to two groups. In one the condition is usually benign, the severe and malignant forms being in the minority; while in the other the process is essentially grave, although abortive cases may occur. Thus typhus exanthematicus is one of the most fatal plagues, yet we know now that it may rarely occur in a mild, sporadic form. In scarlatina exactly opposite conditions occur.

## GRADING MILK AND CREAM.

A new method of grading milk has been adopted by the health department of the District of Columbia and is described by Dr. W. C. Woodward, health officer of the District of Columbia, in Reprint No. 117 from Public Health Reports. One hundred points are allowed for the dairy farm, both equipment and management; 100 points are allowed for the cattle; 100 points are allowed for the milk distributing station, if the milk is not distributed directly from the farm; 100 points are allowed for the chemical analysis; and 200 points are allowed for the bacteriological examination. The total number of possible points is 600 if there is a milk distributing station and 500 if there is no such station. By dividing the total by the number of points possible a figure is obtained in the form of a decimal fraction representing the grade of milk. Any unusual conditions bearing upon the nutritive quality of the milk or on its wholesomeness, but not susceptible of being reduced to a percentage basis, are to be set forth in an explanatory note, if the grade is computed during the continuance of such conditions; such, for instance, as a milk-borne outbreak of typhoid fever or other contagious disease. The manner in which the cattle and the dairies are rated and the rating of chemical analysis are all set down in the reprint, but are somewhat too complicated, or rather it might be said too lengthy, to be described here.

However, it may be noted that the plan outlined for the evaluation of the bacteriological findings lays down a basis for raw milk different from that for pasteurized milk. This is fair when the ratings of two or more samples of milk of the same class are to be compared, but it would be manifestly unjust, as is pointed out in the article, to compare such a rating of raw milk with a rating of pasteurized milk unless the difference is taken into consideration. In order to prevent such unfair comparisons, ratings for pasteurized milk should be accompanied always by some descriptive term such as the word "pasteurized" and if it is desired to compare the ratings of pasteurized milk with a rating of raw milk, both should be reckoned on the same basis, preferably that for raw milk. The advantages claimed for the method of grading milk here described are that it will reduce to a minimum the influence of the personal equation. The scoring of a single farm by the same dairy farm inspector at different times or, as will most commonly be the case, the scoring of different farms by different inspectors at different times, and the scoring of the dairy or milk shop at yet different times and by other inspectors, will reduce the personal equation very much; and with respect to all, except possibly the very last score, which will be taken into consideration when any given milk grade is computed, the interested farmer or milk dealer will have the opportunity to appeal from the inspector to the higher supervising officer before the score enters into the grading.

## Treatment of Frambesia with Salvarsan.

Frambesia or yaws, although seldom in itself fatal, is a disfiguring, unsightly, and repulsive affection. Many hold that it is of syphilitic origin, and from the manner in which it has been successfully treated by the same remedies which are effective in syphilis it would seem that this contention is correct. Now Passed Assistant Surgeon E. U. Reed, U. S. Navy, reports in the *U. S. Naval Bulletin* for April cases of frambesia in Samoa cured by the administration of salvarsan, a result which gives further weight to the evidence in support of the complaint being of syphilitic origin. From September 1, 1911, to April 1, 1912, eighty-three cases of frambesia were treated with salvarsan at the naval station, Tutuila, Samoa. The drug was neutralized with 2 per cent. sodium hydrate solution and injected into the muscles of one buttock. Complete and permanent cures were recorded in fifty-three cases. In practically all of these cases the yaws lesions dried up rapidly, the crusts fell off, and in 8 to 10 days the only traces of the disease were red discolorations of the skin where previously had been large elevated masses of tissue. The doses given for the different ages depended somewhat upon the severity of infection and the strength

of the individual. According to Reed no syphilis has ever been recorded as contracted in American Samoa and he has seen no cases of syphilis among the Samoans after holding large clinics for over a year. This is possibly because they have become so thoroughly syphilized that the poison of the disease can produce only the milder lesion of yaws. The use of salvarsan, says Reed, has so greatly diminished the prevalence of the affection in the island that children with large repulsive yaws lesions are seldom seem, whereas they were formerly a common sight.

### The Overlapping of "Diatheses" and "Constitutions."

The reader of to-day cannot fail to be impressed with the great number of conditions alleged to form anlage for disease—and this, too, in the days of modern biometry. To enumerate only a few we have Czerny's exudative diathesis, enteroptosis, Stiller's asthenia, spasmophilia, hypothyroidism, intestinal toxemia, and status thymico-lymphaticus. All these conditions are described minutely by their sponsors; hence it is the more surprising to find that two conditions apparently without any natural affinity present in part very similar syndromes. That two conditions representing inferiority should coexist at times in an inferior organism is to be expected, but it is difficult to understand how an acquired condition like intestinal autotoxemia should have many symptoms in common with hypothyroidism. At the Deutscher Congress f. innere Medizin, held last month at Wiesbaden, Jamin recognized a basic condition "juvenile asthenia," derived from Stiller's general conception of asthenia, and made chlorosis its chief expression. The main symptoms are weakness and pallor, the latter not accounted for by the red blood cell count, which may be normal in the worst cases. The opinion is growing that these various anlage for disease all repose upon developmental anomalies of the glands of internal secretions. This view does not exclude a like origin for conditions first apparent late in life.

### The Most Recent Case of Thoracotomy for Pulmonary Embolism.

The claim has often been heard that under an optimum of circumstances life will yet be saved in embolism of the pulmonary artery. A case recently reported by Rose before the Aerztlicher Verein of Hamburg (*Münchener medizinische Wochenschrift*, May 20) appears to show that the most favorable conditions by no means assure recovery. Rose was getting ready to operate on a patient when word was brought that a woman on the fourteenth day after laparotomy had suddenly collapsed while laughing. The surgeon at once transferred his activities to the second patient and at the end of two minutes (!) had her pulmonary artery exposed. From it he extirpated an embolus 12 cm. long and as thick as a man's finger. Despite artificial respiration, direct heart massage, and injections of adrenalin and digitalin the patient died.

### Natural Color Photography and Forensic Medicine

A natural query has always been, "What advantages do autochromes possess over photographs artificially colored?" granted, of course, that the tints can be accurately reproduced. The answer is equally obvious, for natural colors are to be desired, especially when something of material import is actually at stake. An artificially colored exhibit in a criminal trial, when the color was the point at issue, should constitute evidence of considerable value. Burger exhibited, on Feb. 17, forty autochromes of forensic import to the Berlin Society of Psychiatry and Nervous Diseases (*Berliner klinische Wochenschrift*, April 21). These were intended for use in identification of individuals, especially the drowned, and of blood stains, ecchymoses, burns of various degrees, gunpowder stains, and intracutaneous marks. Certain tissues of forensic importance rapidly lose their normal hue on preservation and these should be photographed in natural colors. The "cyanide of potassium stomach" is a case in point. Autochromes of blood spectra, blood crystals, etc., are practicable for the same reason. It is self-evident that autochromes are of great value in teaching.

### Sanatoria and the Public Health.

The statement has frequently been made that sanatoria for the treatment of those suffering from tuberculosis are of value, but that up to a comparatively recent date their value has been somewhat exaggerated. The sanatorium is needed in the fight against tuberculosis, but it is only one factor and probably not the most important. In the *Canadian Public Health Journal*, April, 1913, is a paper by W. B. Kendall, physician-in-chief of the Muskoka Cottage Sanatorium and the Muskoka Free Hospital for Consumptives, in which is discussed the value of sanatoria from the standpoint of public health. It is rightly shown that a person suffering from a communicable disease is a source of danger to the community, and as ignorance is possibly the greatest predisposing cause of any disease, it is at once necessary and important that sick persons should be taught, and this with all promptness and thoroughness. It is in this regard that sanatoria are of the greatest possible importance to the patients as well as to the general public.

## News of the Week.

**Deaths in New York.**—During the week ending June 7, there were reported in New York a total of 1,447 deaths, as against 1,338 in the corresponding week of 1912, an increase of 109. There was an increase of 61 deaths of children under five years of age, and of 56 deaths of persons between five and sixty-five, and a decrease of 8 deaths of persons over sixty-five.

**New Nurses' Home.**—The Red Cross Hospital on Central Park West, New York, is about to increase its facilities by adding two floors to the four-story rear extension of the hospital building, at a cost of $20,000. The addition will be used as a nurses' home.

**Seaside Hospital.**—The reconstructed main building of the Seaside Hospital maintained by St. John's Guild at New Dorp, S. I., was dedicated on June 12. The new building is a model of its kind, the wards being in wings open on either side with a solarium at the ends. It is of fireproof construction, can accommodate 400 patients, and was erected at a cost of $150,000. Dr. Abraham Jacobi, president of the Medical Board of St. John's Guild,

was one of the speakers at the dedication exercises.

**Public Health Service.**—The United States Public Health Service will hold examinations on July 7, 1913, and on August 4, 1913, for the purpose of examining candidates for admission to the grade of assistant surgeon in the Public Health Service. Candidates must be between 23 and 32 years of age, of good moral character, and graduates of a reputable medical college with at least one year's hospital experience or two years' professional work. Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order. After four years' service assistant surgeons are entitled to examination for promotion to the grade of passed assistant surgeon. Assistant surgeons receive $2,000, passed assistant surgeon, $2,400; surgeons, $3,000; senior surgeons, $3,500; and assistant surgeon generals, $4,000 a year. Further information may be obtained upon application to the "Surgeon General, Public Health Service, Washington, D. C."

**Safeguarding Foodstuffs.**—Basing its action upon a recently enacted State law providing that no diseased person shall be allowed to handle foodstuffs in stores, restaurants, bakeries, or factories, the Board of Health of Grand Forks, N. D., has issued an order making employers liable to criminal prosecution if they employ in such work any one who is affected with a contagious or infectious disease.

**Bulletin of the Manila Medical Society.**—The Council of the Manila Medical Society announces that in consequence of an extensive fire which has destroyed manuscript, plates, and other property, the publication of the *Bulletin of the Manila Medical Society* has been suspended indefinitely.

**Dr. Robert Abbe** of New York sailed for Europe, June 10. He will present the subject of "Radium in Malignant Disease" before the International Congress of Medicine in London, August 7, having received special appointment for this purpose two years ago.

**Fordham University.**—At the annual commencement of Fordham University, New York, on June 10, the degree of doctor of medicine was conferred upon twenty-eight graduates of the Medical School.

**Cornell University.**—Nineteen graduates, including two women, received the degree of doctor of medicine from Cornell University, at the annual exercises of the Cornell Medical College held in New York on June 12. Addresses were made by Dean Polk and by Acting President Crane of the University, and it was announced that every member of the staff had secured a hospital appointment. The John Metcalfe Polk Memorial Prizes were awarded to Morris Kush, first; J. S. Baldwin, second, and Henry R. Miller, third; and the Whiting prizes in otology to J. S. Baldwin, first, and John R. Quinn, second.

**Commencement Exercises.**—At the eighty-eighth annual commencement of the Jefferson Medical College, Philadelphia, on June 7, the degree of doctor of medicine was conferred on 126 graduates. It was announced that Mr. Daniel Baugh, one of the trustees of the College, has agreed to enlarge the Baugh Institute of Anatomy so that it will be the equal of any similar institution in the country.

The Medico-Chirurgical College, Philadelphia, on June 6, at its thirty-third annual exercises conferred the degree of doctor of medicine on sixty-one graduates.

At the twenty-seventh annual commencement exercises of Temple University of Philadelphia, on June 5, thirteen graduates in medicine received their degrees.

**Honorary Degrees Conferred.**—Dr. Simon Flexner, Director of the Rockefeller Institute for Medical Research, New York, and Dr. David Linn Edsall, professor of clinical medicine in the Harvard Medical School, Boston, received the honorary degree of doctor of science at the commencement exercises of Princeton University held on June 10.

At the seventieth annual commencement of Villanova College on June 12 the honorary degree of Doctor of Laws was conferred on Dr. Charles F. Nassau and the degree of Doctor of Science on Dr. George H. Meeker.

Dr. Abraham Jacobi of New York received the honorary degree of Doctor of Laws at the commencement exercises of the Jefferson Medical College, Philadelphia, held on June 7.

**Philadelphia Health Board.**—Dr. D. Braden Kyle has resigned from the Philadelphia Board of Health and Dr. Walter H. Andrus has been appointed in his stead.

**Anti-Vivisectionists in Philadelphia.**—Following their threats of the previous week, the anti-vivisectionists of Philadelphia on June 14 obtained warrants for the arrests of five members of the Medical Society of the University of Pennsylvania on the charge of cruelty to animals. The five men, constituting the committee in charge of the animal house, are Prof. Alfred N. Richards, Prof. Richard M. Pearce, Prof. Alonzo E. Taylor, Prof. Edward T. Reichert, and Prof. Allen J. Smith. It is alleged that they have performed operations upon animals without administering anesthetics, and have performed other acts of cruelty. A general denial of the charges has been made, and the case will be carried, if necessary, to the highest tribunal in the State.

**To Test Vaccine.**—After repeated delay the Friedmann Institute in New York has complied with the requirements of the Board of Health, and by furnishing the specimens and data necessary has made it possible for the Health Department to proceed with a test of the vaccine introduced by Dr. Friedmann. Some months will probably elapse before the Department is prepared to make any final report, and in the meantime it is rumored that the institute may remove to some town in New Jersey nearby.

Recent newspaper despatches state that at a meeting of the Berlin Medical Society Dr. Friedmann's method of treatment was bitterly assailed, and it was stated that his promise to inform the society as to the details of his preparation had not been entirely fulfilled.

**Gifts to Charity.**—By the will of the late Lydia Varnall of Media, Pa., the sum of $3,000 is bequeathed to the Chester Hospital, and a like sum to the Crozer Home for Incurables, while one-fifth of the residuary estate, the value of which is not stated, is left to the Rush Hospital for Consumption and Allied Diseases.

By the will of the late James F. Hope of Philadelphia one-tenth of his estate is, at the death of his widow, to be divided equally among the Presbyterian Hospital, the Jefferson Hospital, and the German Hospital, and such other hospital as may at the time be devoted to the treatment of contagious diseases, or, if none such exists, to the Episcopal Hospital.

The Brooklyn Hospital and the Brooklyn Eye and

Ear Hospital of Brooklyn, N. Y., receive bequests of $5,000 each by the will of the late Charles A. Hull of that city.

**American Society for the Control of Cancer.**—At a meeting on June 9 of the executive committee of the recently formed organization to fight cancer in this country the above title was selected. At the same time a committee was appointed to ask for the co-operation of the American Medical Association at its meeting in Minneapolis.

**International Congress for Neurology, Etc.**—The Neurological Society of Switzerland has undertaken the organization of an International Congress for Neurology, Psychiatry, and Psychology, to be held at Berne, Switzerland, on September 7 to 12, 1914. This will be a continuation of the Congress held at Amsterdam in 1907, at which time the Swiss Neurological Society was commissioned to prepare for a second meeting. The organizing committee consists of Prof. Dr. Dubois, Berne, *President;* Prof. Dr. von Monakow, Zürich, and Dr. P. L. Ladame, Geneva, *Vice-Presidents,* and Dr. L. Schnyder, Berne, and Dr. O. Veraguth, Zürich, *Secretaries.*

**Rhode Island Medical Society.**—At the 101st annual session of this society, held in Providence on June 5, the following officers were elected for the ensuing year: *President,* Dr. John W. Keefe; *Vice-Presidents,* Dr. Stephen A. Welch, and Dr. Frank L. Day; *Secretary,* Dr. Jay Perkins; *Treasurer,* Dr. Winthrop A. Risk; *Librarian,* Dr. George D. Hersey, all of Providence.

**American Medico-Psychological Association.**—At the annual meeting held in Niagara Falls the following officers were elected on June 13: *President,* Dr. Carlos F. MacDonald, New York; *Vice-President,* Dr. S. E. Smith, Richmond, Ind.; *Secretary,* Dr. Charles G. Wagner, Binghamton, N. Y. The association will meet in Baltimore in 1914.

**Dr. Algernon Thomas Bristow.**—The following memorial note was adopted at a recent meeting of the New York Society of Anesthetists:

"Be it known to all men, and especially to those nearest and dearest to him, that the New York Society of Anesthetists in executive session assembled, drafted this expression of respect, admiration, and deep regret at the recent loss of their supporter and advocate, Algernon Thomas Bristow.

"His editorial and practical hospital support of the advancement of the art of general anesthesia has time and again aroused the admiration and emulation of this body of anesthetists, and so active and influential has this work among his many followers been, that this society wishes itself placed on record as considering it monumentally constructive and its cessation as a great loss to the surgical world.

W. C. Woolsey,
G. Tayloe Gwathmey,
A. F. Erdmann,
Committee.

**Obituary Notes.**—Dr. John Mutting Farrar of New York, a graduate of the Jefferson Medical College, Philadelphia, in 1874, and a member of the New York State and County Medical Societies, and of the American Medical Association, died at his home in June 12, aged 74 years.

Dr. B. Frank Barnes of Newark, Ohio, a graduate of the University of Wooster, Medical Department, Cleveland, in 1895, and a member of the American Medical Association, and of the Ohio State and Licking County Medical Societies, died in the Lakeside Hospital, Cleveland, following an operation for gallstones on May 29, aged 47 years.

Dr. Samuel M. Hardman of Clarksburg, W. Va., died at his home after a long illness, on May 31, aged 62 years.

Dr. John Neff of Baltimore, Md., a graduate of the New York University Medical College in 1858, and a member of the American Medical Association, and the Maryland State and Baltimore City Medical Societies, died at his home after a long illness, on June 5, aged 81 years.

Dr. Harry E. Snow of Belmar, N. J., a graduate of the Rush Medical College, Chicago, in 1887, died at his home, after a short illness from erysipelas, on June 12, aged 55 years.

Dr. Augustus S. Smith of Lebanon, Pa., a graduate of the Pennsylvania Medical College, Gettysburg, in 1859, and at one time prothonotary of Lebanon County, died recently, at his home, aged 73 years.

Dr. William Joseph Wickman of San Rafael, Cal., a graduate of the University of California, Medical Department, San Francisco, in 1883, and a member of the American Medical Society, and of the California State and Marin County Medical Societies, and formerly county health officer, and city physician of San Rafael, died at his home suddenly on May 29, aged 58 years.

Dr. Harmon George Howe of Hartford, Conn., a graduate of the University of Vermont in 1873, and of the College of Physicians and Surgeons, New York, in 1875, a member of the American Medical Association and of the Connecticut State and Hartford County Medical Societies, first director of the Hartford Hospital and chairman of the Medical board, was killed in an accident on the New York, New Haven & Hartford Railroad at Stamford, Conn., on June 12, aged 63 years.

Dr. Owen C. Spear of Wilmington, Del., a graduate of the Jefferson Medical College, Philadelphia, in 1906, and a member of the Delaware State and Newcastle County Medical Societies, died in the Delaware Hospital, from peritonitis, following an operation for appendicitis, on June 2, aged 49 years.

Dr. Walter A. Jensen of Melbourne, Ia., a graduate of the State University of Iowa, College of Medicine, in 1911, died on June 1, after a long illness, aged 35 years.

## Correspondence.

### OUR LONDON LETTER.

(From Our Regular Correspondent.)

GENERAL MEDICAL COUNCIL—NEW BLOOD PARASITE—OPIUM AND ARSENIC—MIDDLESEX HOSPITAL AND RADIUM—OBITUARY.

London, May 30, 1913.

The summer session of the General Medical Council was opened on Tuesday with the presidential address by Sir Donal MacAlister, K.C.B., who then vacated the chair, his term of office as president having expired. He was forthwith unanimously re-elected, and taking the chair returned thanks for the honor. The several committees were also appointed. In his address the president referred to most of the incidents of the past year. Last November he reported what had been done to give effect to the resolution of Council that in case of Irish Home Rule becoming law it was desirable the control of medical legislation should be reserved

to the Imperial Parliament. The Government, however, paid no attention to the representations made and it was doubtful whether another opportunity would occur for pressing the matter, but if it should the president assumed the former instructions would be operative. The bill for amending the provisions for the elections of representatives on the Council had been withdrawn by the Government, and there seemed little prospect of anything being done as to that this year. The president then related what had been done by the committee on the Insurance Act, in accordance with the directions of the Council. Its suggestions for amending the regulations had been acceded to, except in regard to the question of hospital or institutional treatment of patients needing services beyond the competence of the ordinary general practitioner. It was said that any change as to that could not be made by the regulations, but only by further parliamentary action. In one form of agreement no provision is made as to an anesthetist for operative cases. The committee has brought this defect before the Commissioners and the correspondence about it is not yet concluded. Early in the year during the acute discussions about the Insurance Act attention was called to warning notices which had been previously issued by the Council in regard to methods of advertising and canvassing which the Council disapproved. A further advance was reported in the direction of medical reciprocity within the Empire, the degrees in medicine and surgery of the University of Hong Kong being recognized for registration in the Colonial list. The Medical Council of Canada, which will be meeting almost immediately, will probably do as New Brunswick has already done, by placing on its register any resident duly registered here.

The Council considered *in camera* applications for restoration to the register, of which two were granted, and then proceeded to penal cases. One of these last was for impersonation by a man who had masqueraded as Muscat, and Muscot, and More, also afterwards as Anthony Ciaramelli. He had been run to earth by the Defense Union, to which the president expressed the thanks of the Council, and left them to communicate the result to the genuine Dr. Ciaramelli of your city. In one case judgment was postponed until the November session, and in another no action was taken.

Bacteriologists seem to have been taken aback by the claim of Dr. Helen Chambers to have demonstrated that a protozoon flagellate is always present in human blood. The claim was made at the Royal Society of Medicine (Section of Pathology) on the 20th inst. Some seemed to look upon the assertion as incredible, but others were willing to return to their microscopes and test the matter. One says the protozoa are not toxic as a rule, but that is a long way from pronouncing them normal constituents of the blood. Dr. H. D. McCulloch says, in the *Practitioner,* "there is no gainsaying facts," and recalls that quite recently in the *Lancet* he attempted to describe how nonflagellate organisms gained entrance into lymphatic glands, and now he accepts the evidence of the ingress of flagellates into the blood. Apart from their own properties he thinks the micro-organisms are influenced by the qualities of the media in which they are found. Some may remain suspended in a liquid or in a gas, while others exert their powers more easily in a semi-solid or viscous medium. A rigid, spiral form, rotating on its own axis, would be more adapted to a semi-solid or even solid medium than a rigid undulating nonrotating form; as an earthworm moves briskly through soft clay but is helpless in water, as a fish is on land.

Dr. McCulloch avers that is easy to demonstrate the micro-organisms within a few minutes of the abstraction of blood. It is centrifugalized and allowed to clot; then they emerge in small numbers at first but more later. As many as ten may appear in the field and can be shown in active motion, using an oil-immersion lens. Their activities can be watched with dark ground illumination. Some speculation is going on as to how far they may be associated with disease.

In the three lectures subsequent to the one I noticed which constituted the Gresham course, the professor, Dr. F. M. Sandwith, spoke of opium and arsenic. It should be remembered that these lectures are not wholly or primarily addresses to the profession, but afford an opportunity of warning the educated public, which has this year been exercised in regard to powerful poisons. Opium had, Dr. Sandwith said, exercised an immense power for good and evil. Like alcohol, it was not restorative, could only lull into temporary oblivion. About half the deaths from poision were due to opium, but it did not affect criminal statistics, as its action was not to induce paroxysms of violence. It had been smoked in China since the seventeenth century, and in 1906 it was estimated that 27 per cent. of Chinese adults were smokers of it. The worst form of poisoning was by injection of morphia and no doubt physicians have at times allowed these to be given by nurses and others. Patients learned the effects, abused the drug, and became its victims. It was a bitter lesson for the doctors.

Dr. Sandwith similarly gave some interesting facts relating to arsenic, and said some of its preparations were used in malaria, skin diseases, and sleeping sickness, and so on. Then he told how Syrian women used it as a beautifier, as they thought, and the superstition had spread. It is the principal ingredient of the face lotions vended by quacks, but dangerous. It has been known to kill the users by being absorbed through the skin. Besides there are instances of these and other arsenical preparations being swallowed, accidentally, suicidally, and criminally. Brinvilliers, the Marchioness with a lust for murder, used it under the notion that it disappeared from the body after death, but that was not the case. It can be detected long after exhumation.

Prince Alexander of Teck yesterday, at a meeting of governors of the Middlesex Hospital, named three urgent needs which he believed would be generously met by those able to assist. These were (1) the improvements in the new operating theater, as to which he declared it absolutely essential to make it as perfect as possible; (2) extension and improvement of the children's wards; (3) improving the sanitary arrangements in the southwest wing. They hoped some assistance would be granted by King Edward's Hospital Fund, and their faith in human sympathy for the remainder continued unshaken. His Serene Highness referred to the devotion of the staff and their work with radium, "the new weapon" of research in their hands. Dr. Pasteur, in seconding the report, said they had difficulty in getting sufficient radium, it was so costly, and could not be used in small quantities. Sir A. Pearce Gould said radium was unlike a drug, not lost by being used, but repre-

sented capital. Even when not in use it was storing up its emanations. Prince Alexander was re-elected chairman for the ensuing year and the report adopted.

Deputy Inspector-General W. R. White, R.N., died on Sunday in his sixty-third year. He was a Dublin graduate, B.A., M.B., and M.Ch. He took part in the Gambia Expedition, 1894, when he was wounded and mentioned in dispatches. He accompanied Lord Sackville in his exploration of the upper waters of the River Platte. For various services he received the thanks of the Admiralty, and in recognition of them was further created C.B., and awarded the African medal with clasp. He published an important monograph on malarial fevers.

## OUR LETTER FROM THE PHILIPPINES.

(From Our Regular Correspondent.)

LOW DEATH RATE IN MANILA—SCHISTOSOMUM JAPONICUM—VENEREAL PROPHYLAXIS—BERIBERI—THE PLAGUE—CHOLERA CARRIERS.

MANILA, P. I., April 10, 1913.

THE death rate for Manila during the month of March still remained phenomenally low, there having been reported 451 deaths, as against 732 for the same month last year. This breaks all records for March since American occupation. The improved health is no doubt largely due to the better water supply that is now furnished the city and the modern sewer system which is now coming more and more into general use, although the many other sanitary improvements, such as reduced number of mosquitos, proper garbage disposal, frequent street sweeping, etc., in all probability have aided in the result.

The regular monthly meeting of the Manila Medical Society was held at 8:30 P.M. in the amphitheater of the College of Medicine and Surgery of the University of the Philippines. Dr. Rembe gave a brief description of his operation for cataract without iridectomy and showed two cases in which the operation had been done.

Dr. Vernon Andrews exhibited specimens from a case of *Schistosomum japonicum* which came from a Filipino and, so far as known, this was one of the first cases that has been reported among this race. He stated that the literature showed that there had been a total of 17 cases reported in the Philippine Islands, but that further investigation led him to the opinion that probably there had been some duplication in the cases previously reported.

The next paper was read by Major Wolfe of the Army Medical Corps, and in this he gave an account of the venereal prophylactic measures that are in use among the troops stationed at Fort McKinley. He presented a series of tables which showed a most marked diminution in the number of venereal cases since the War Department order had gone into effect which stopped the soldier's pay during the time that he was being treated for a venereal disease. Prior to that time the prophylactic measures were theoretically in force, but in their practical application it was found that many of the soldiers evaded taking the treatment. It was frequently found, for instance, that a soldier who desired to spend the evening out would send a substitute under his name to take the treatment. Again, it happened that the men would take the treatment and immediately expose themselves again without taking the prophylactic measures the second time. The treatment that is used at present consists in thorough washing of the penis with warm water and tincture of green soap. This is followed by the instillation of a few drops of a four per cent. solution of argyrol, and then the fore part of the penis is thoroughly rubbed with calomel ointment. Major Wolfe lays special stress upon the thorough cleansing and the application of the ointment to the frenum; the reason being that there are many cases on record where chancroids developed around the frenum that had not been thoroughly cleansed.

The last paper of the evening was by Vedder and Williams and was read by Captain Vedder of the Army Medical Corps, and who is also a member of the Board for the Study of Tropical Diseases as they exist in the Philippine Islands; entitled "Beriberi." In addition to the facts these authors have brought forth in papers which have been published heretofore with regard to beriberi, they gave an interesting series of experiments in which they showed that the use of rice that was mouldy and had been stored for over a year in a damp place apparently had no effect in producing polioneuritis gallinarum, provided that the rice was of the undermilled or unpolished variety, that is that the pericarp had not been removed and the rice contained at least 4/10 of one per cent. phosphorus pentoxide. This point was considered of practical importance, because it has been frequently asserted by medical men that rice which has been stored, especially that which has been kept in damp places, would cause beriberi, regardless as to whether it was of the unpolished variety or not.

He also expressed the view, but stated that as yet he had no experimental facts to support it, that perhaps the wet and dry forms of beriberi were caused by the lack of a distinct substance in the diet which produced each disease, and that perhaps an extract made from rice polishings might cure dry beriberi and not wet beriberi, which would simply mean that all of the necessary essentials had not been extracted from the polishings.

Since the beginning of the year there have been 8 cases of plague, with 7 deaths, in the Philippines. A majority of these occurred among young adults under the age of 16 years, mostly being boys. During the past month there has been a sharp increase of plague infection among the rats of the Tondo district. Two cases of human plague, one in a man and the other in a woman, were found at Malolos, which is a town on the railroad, situated about 24 miles north of Manila. Both of these were traced to a house in Manila on Calle Aquino in the district of Tondo and in close vicinity to a section where plague-infected rats had been found. As both of these cases occurred well within the incubation period of plague, it has been assumed that the disease was contracted in Manila and that on account of the fear of being taken to the communicable disease hospital the afflicted persons fled to Malolos. After the discovery of the cases an active rat-catching campaign was conducted in Malolos for a period of two weeks, but no plague-infected rats were found.

The Bureau of Health, in order to combat the rat plague of Tondo, has somewhat changed the plan of campaign. Instead of the greatest stress being laid upon the actual catching of rats, the principal thing kept in mind at present is to destroy rat nests, and secondly to catch as many rats as possible and then to rat-proof the premises. One gang of laborers composed of about 100 men is divided into three

sections, each under the charge of an experienced sanitary inspector, and these go from house to house and make a thorough systematic search for rat-breeding places. After the search of the house proper is completed, the yards, woodpiles, old junk, rubbish, and everything likely to harbor rats are moved about so that the rat nests may be discovered and destroyed. Particular attention is given to spraying with an insecticide so that the fleas may not escape. In this way an enormous number of rats are also caught and the chances of catching those that are likely to be infected are very much increased. It is thought by constantly changing the places of abode among rats, there is less likelihood of the disease spreading among them and also that the chances are very much reduced of plague-infected fleas gaining access to human beings, that have come from rats that have died in rat nests.

In view of the great importance that has been attached by the Javanese sanitary authorities to destroying rats in hollow bamboos, special stress has been laid upon finding similar breeding places in the Philippines; but in spite of the fact that this was constantly kept in mind, it was only recently that rats were actually found in bamboos. In a house located at 140 Calle Perla a man was found dead with plague. In a piece of bamboo in which the partition of the first joint had been gnawed through a mummified rat that had apparently died of plague was found. The bamboo was placed horizontally near the head of the cot on which the man slept, and it would appear probable that the plague-infected fleas on the death of their host left the bamboo and attacked their human victim.

In the Philippines it is customary to make stool examinations of all steerage passengers and crews that come from other Oriental countries. Last year several cholera carriers were found. A short time ago a person who had many of the clinical symptoms of cholera was found upon careful laboratory examination to have *Balantidium coli* dysentery.

**1. Relation of Bacterial Metabolism to Internal Medicine.**—A. I. Kendall presents evidence to show the extent to which utilizable carbohydrate spares protein and protein derivatives from bacterial attack. The carbohydrate protects protein largely from bacterial breakdown. The sparing action is not complete, but results in the practical elimination of nitrogenous products, incidental to bacterial development, some of which may be toxic, and the substitution for them of substances which are non-nitrogenous, which may be irritative, but probably never truly toxic. The principle involved may be made use of theoretically in the treatment of diseases of bacterial origin, in which the anatomical features are such as to permit the utilization of carbohydrate by the invading microorganisms. The object of the diet rich in carbohydrates is twofold: physiologically to provide the patient with a readily assimilable food requiring a minimal amount of digestive energy to prepare it for the tissue needs, and bacteriologically to shift bacterial metabolism from the destruction of body tissue for their food requirements to the utilization of carbohydrate for at least the major part of their dietary needs. The shifting of metabolism to sugars appears to deprive these microbes of one of their most potent weapons of offense, and forces them to act on the defensive: forcing the parasite to act on the defensive theoretically at least permits the host to rally and to strengthen its defensive and even its offensive powers earlier in the battle. The initial damage, brought about when the host is temporarily overwhelmed by the initial onslaught of the invaders (which is accomplished largely during the incubation period of the disease) cannot be estimated at present, and perhaps cannot be undone. The final struggle between host and parasite can be influenced directly and favorably.

**2. Vaccine Treatment of Common Colds.**—J. W. Fisher states that colds can be largely prevented by the reasonable isolation of every case, and preventive inoculation. Colds can be aborted or their course shortened by vaccine treatment. The treatment of acute and chronic inflammation of the respiratory tract by vaccines is specific. A symptom complex resembling influenza may be due to other organisms. While bacterins are invaluable in the treatment of acute and chronic infections of the nose and respiratory tract, and are attended with almost constant success, it is as a prophylactic that they give most brilliant results. The immunity occasionally lasts a year or more, but usually from four to six months is the average duration. To the individuals subject to recurrent colds, as many are during the winter months, it proves a great boon. In these cases it is well to make an autogenous vaccine from the first cold, to which may be added, if so desired, the other "cold germs" from stock. This may be given in increasing dosage with seven-day intervals, until four to six doses are administered, which generally produces sufficient immunity for several months. If one prefers to wait until the onset of the next cold before beginning the treatment, the attack can almost invariably be aborted and immunity completed. This procedure may be repeated at the end of six months, or delayed until such time as necessity demands. The dosage which seems to give the best results is as follows: pneumococcus, *M. catarrhalis, M. tetragenus*, each 125,000,000; streptococcus, 50,000,000; *Bacillus influenzæ, B. septus, B. Friedlander*, about 100,000,000; staphylococcus, 400,000,000 to 800,000,000. The vaccine should be prepared so that eight minims contain the requisite number of sterile germs, as larger amounts of fluid are more apt to produce local reactions. The best site of inoculation is deep in the deltoid muscle.

**3. An Etiological Factor in Carcinoma.**—H. W. Nowell describes a procedure by which a substance or substances may be isolated from carcinomata, the method precluding the presence of organic life in the end product. This end product has been shown to be of a highly toxic character. The peritoneal exudate produced by a fatal intoxication is far more toxic than the original substance. The tumor substance has been shown to possess not only a general but also a specific toxicity, since on injection into rabbits in doses of less than lethal amount it will produce well-defined, well-characterized carcinomata, the site of the primary lesion being different from and independent of that of the injection. The appearance of the primary lesion is followed by the development of numerous metastatic foci in different parts of the body, while the characteristic cachexia manifests itself. The poisonous tumor preparation has been shown to be characteristic of carcinomata. By the repeated injection of very small doses a large number of rabbits have been immunized. The serum from the animals thus immunized possesses the power of antagonizing the toxic action of the tumor substance. This has been demonstrated by injections of the serum either previous to or simultaneous with that of the tumor poison. In both events no effect is ob-

served from quantities of the poison which, if injected alone, would produce a rapidly fatal intoxication. With the simultaneous injection of poison and antibody it has been shown that one part of the latter will effectually antagonize 99 parts of the former.

**2. Gallstones Producing Intestinal Obstruction.**—W. W. Babcock notes that intestinal obstruction may occur when gallstones having a greater diameter than two centimeters enter the small bowel. Much larger gallstones pass into the large intestine without producing obstruction. Gallstones of sufficient size to produce intestinal obstruction are, as a rule, too large to pass through the biliary ducts without some ulcerative or perforative process. It is rare to find a dilated communis with a greater lumen than one centimeter, and, in conjunction with such dilatation of the duct, a marked distal narrowing, usually situated in the region of the head of the pancreas or in the wall of the duodenum, will be found. It is obvious, therefore, that large gallstones may enter the intestinal tract in one of three ways: (1) They may gradually erode their way through the cysticus and the communis by a combination of proximal and circumferential dilatation and distal pressure necrosis and ulceration. (2) The duct or gall-bladder containing the calculus may become adherent to an adjacent portion of the stomach or bowel, and a direct perforation occur with the transference of the stone from the biliary to the gastro-intestinal canal. The stone may perforate the gall-bladder or duct, and be received into a cavity of inflammatory formation, and from this cavity or abscess the stone may then perforate the wall of one of the hollow organs of the abdomen. In this way the gallstone may enter the stomach, the small intestine, colon, or rarely some other viscus, as the urinary bladder. Gallstones, when in the general abdominal cavity, share the property of other harsh foreign substances of tending to penetrate adjacent hollow viscera. Intestinal obstruction from gallstones is unusual, and, as would be expected, usually occurs in elderly women who have long suffered from gallstone "dyspepsia."

**4. Chemical Control of Wassermann Reaction.**—D. M. Kaplan urges extreme caution in the interpretation of the clinical significance of this very complex reaction. A more definite basis than the side chain theory should be at one's command for the gauging of syphilitic serums. The determination of amino nitrogen in the serums from syphilitic patients will lend itself to further elaboration and will give useful results. A serum in which a positive Wassermann reaction has been obtained is very dubious in a patient whose amino nitrogen is normal. The amino content of syphilitics is frequently very much diminished, although the Wassermann reaction may be negative. Whether a patient should be treated until the amount of amino nitrogen is restored, giving one another gauge as to therapy, is for the future to determine. The paretic patients who presented a normal amino nitrogen in one instance and showed a tendency to an increase in another are in very good physical condition and show no psychic stigmata of the disease. The characteristic pupils are still evident.

**5. The Problem in Local Recurrent Breast Cancer.**—By C. W. Strobell. (See Medical Record, April 26, 1913, page 774.)

**7. The Treatment of Endometritis.**—G. G. Ward, Jr., emphasizes the following factors in the treatment of endometritis: Leucorrhea, the most prominent manifestation of the disease, comes from the uterine cavity, and not from the vagina. Endometritis may be divided into two great classes, that of bacterial origin and that of non-bacterial origin. In the acute infective cases the discharge is pus containing, active, demonstrable organisms. In acute infective cases the treatment to be observed is masterly inactivity. In the common variety of so-called chronic hyperplastic endometritis, which is by far the most frequent type one has to deal with, there is no infection, and the leucorrheal discharge is an excessive secretion from the cervical and utricular glands, the result of venous congestion. The first and most important principle to be observed in treating these cases is to determine the cause of the venous stasis and to treat the same by appropriate measures. The curette is the most valuable means for removing the greatly thickened and diseased endometrium, but if it is used alone, without correcting the cause, only temporary relief of symptoms is obtained. Vaginal douches, glycerin packs, and postural methods, if properly employed, are valuable adjuncts in aiding and improving the pelvic circulation. In the class of cases which are probably dependent upon disturbed ovarian function (either excessive or diminished), such as in the preclimacteric menorrhagias and metrorrhagias, arteriosclerotic uteri, chronic metritis, fibrosis, etc., and which are not benefited by the curette and local measures, one must look for a cure in the direction of ovarian control, possibly by the *x*-ray or by sera from antagonistic glands of internal secretion; otherwise complete ablation of the ovaries or hysterectomy is the only resort. In submitting curettings to the pathologist it is imperative that the relation of the time of the curetting to the menstruation be stated, in order to obtain an opinion of value.

**1. Epidemic Meningitis in Children Below Two Years of Age.**—H. Koplik calls attention to the difficulties in the diagnosis and treatment of cerebrospinal meningitis in children under two years of age. In older children the diagnosis is not as difficult and the prompt use of the Flexner serum has greatly improved the prognosis in such cases. In young infants the symptoms are masked and the dread of making the lumbar puncture needlessly has deterred many from using this valuable method. Particularly difficult are the cases complicated with pneumo-

nia which itself is attended with cerebral symptoms. Many intestinal disorders show misguiding symptoms in infants. While a day's delay is not dangerous with older children, it may be fatal for the baby. For all these reasons the reduction of the death rate has not been appreciable. The virulence of the infection also affects it, different strains differing widely in this respect and there are also cases which cannot be reached by the serum on account of the special sensitiveness of the nervous system at the time it is given. The author urges, therefore, an early resort to lumbar puncture in infants under 2 years of age so that the treatment may begin in time, and also the greatest care in slowly withdrawing the fluid and introducing the serum to avoid traumatism and extreme changes of pressure. In very young patients the temperature is a valuable guide as to the necessity of repeated puncture and serum injection as in older children, but in face of great restlessness and a normal temperature the fluid should be withdrawn by a lumbar puncture and examined for bacteria. If these persist and a cloudy fluid is obtained it is safe to reinject serum rather than to delay and wait for actual culture to determine whether or not the fluid is sterile. Other baffling features are the closure of the foramen of Magendie in some cases and the impossibility of performing a lumbar puncture in many others.

7. **Bilateral and Multiple Ectopic Pregnancy.**—E. McDonald and W. A. Krieger regard multiple ectopic pregnancy as not a rare occurrence if duly looked for. It may be divided into several classes; namely, combined with pregnancy of the uterus, bilateral or twin pregnancy, and two fetuses in the same tube. Twin ectopic pregnancy has been reported a number of times in late years, especially since the treatment by operation has become usual. It is sometimes difficult to determine whether there is a true twin ectopic pregnancy. Many of the cases reported are consecutive ectopic pregnancies not simultaneous in the same tube. They are repeated tubal pregnancies. Treub has photographed five tubal pregnancies of the same age in the same tube and others have reported triplets and twins on one side and a single fetus on the other. Sometimes there is only one sac and sometimes there are two. One ovum may be found free and sometimes both ova are free. Bilateral pregnancy is subject to the same uncertainty; one may be consecutive to the other and the growth may be stopped while the other continues. An interesting fact is that the presence of blood-clot in one tube and of a fetus in the other or of decidual cells in one with a gestation in the other is no proof of a bilateral ectopic pregnancy. Feroni has shown that the microscope reveals decidual cells in tubes that contain blood for whatever reason removed. To make an exact diagnosis of bilateral ectopic pregnancy, either a fetus or chorionic villi must be present in each tube. Two tables of cases collected of bilateral extrauterine pregnancy are given, fifty-two in all. In one, the cases which meet all the conditions are included, in the other the probable cases. Two personal observations of the authors are described in the paper. One patient had apparently three pregnancies, one in each tube and a uterine one which miscarried; in the other patient there was a fetus in one tube and there were chorionic villi in the other.

8. **Erosive and Gangrenous Balanitis.**—B. C. Corbus describes this as a specific venereal disease with local and constitutional symptoms varying with the severity of the infection and due to the symbiosis of a vibrio and a spirochete, always found together. Predisposing causes are phimosis, wetting the labia or penis with saliva, and unnatural sexual relations after alcoholic excesses. It is uncommon in private practice in this country but is fairly frequent in dispensary cases. Probably many cases are unrecognized. The spirochete seems to be similar to one found in Vincent's angina and the vibrio is probably the same as that found in Vincent's angina. Both forms are anaërobic. Both stain by ordinary dyes but the vibrio is Gram-negative while the contrary is the case with the spirochete. The latter is best seen with dark-ground illumination. The ulcers formed are deep with perpendicular edges and are usually mistaken for chancroid as these conditions simulate each other closely and their period of incubation may be the same. The thin yellowish, whitish discharge and the finding of the vibrio and spirochete should help in the diagnosis. The ulcers spread more rapidly and in chanchroid the ulcers are usually more multiple. The indolent adenopathy accompanying the balanitis calls for its differentiation from syphilis. In syphilis the incubation period is longer though the two infections may coexist. In doubt, one should defer the diagnosis of syphilis until its period of incubation is passed and in case of mixed infection the characteristic spirochetes can be easily distinguished. In herpes the condition is mild and one fails to find the organisms. As a prophylactic measure, circumcision should be encouraged; it is impossible for the infection to occur after that. In mild cases cleansing may be all that is necessary. In other cases in which there is the slightest evidence of phimosis an incision should be made. A natural tendency is to burn out these sloughing ulcers but this is needlessly severe. As the organisms are anaërobic, hydrogen peroxide, which liberates oxygen in contact with organic matter, acts as a specific. The ordinary 2 per cent. solution is sufficient but in severe cases a 25 per cent. solution may be painted on the parts.

1. **The Trend of Thought in Recent Pharmacological Research.**—Sir William Whitla first presents a retrospect in the domain of therapeutics. A starting point is found in the epoch-making researches of Crum Brown and Fraser in 1868, on the action of methyl-strychnine. These investigators made the discovery that by linking the organic alkyl radical, methyl ($CH_3$), to the nitrogen of the complex molecule of strychnine, the resulting comparatively slight change in chemical structure altered in a remarkable manner the physiological or pharmacological action of the alkaloid. The alteration was manifested by a change from the convulsant effect on the cells of the cord to a paralytic one on the terminals of the motor nerves, such as is witnessed in the well-known symptoms of poisoning by curare. In discussing the present position with reference to chemical structure and physiological action the author states that innumerable examples have accumulated equally suggestive of this close relationship. Not only is the synthetical chemist able, by altering the structure of the molecule, to intensify greatly the action of the compound; but he can, with equal ease, render the poisonous drug inert by introducing into the molecule such acid groups as the sulphuric, sulphonic, and carboxylic. Thus the poisonous phenol is converted into the inert phenyl-sulphuric acid, and morphine-sulphuric acid can be swallowed with impunity in dram doses. Sufficient instances are not yet forthcoming to justify one in regarding the connection between chemical constitution and physiological action as a definite "law," but only as a working hypothesis. Ehrlich's term "chemotherapy" implies a great deal more than the acceptance of an established dependence of action on chemical constitution.

With this new word another and essentially different working hypothesis leaps into view. Stated in its most advanced form, this second theory attempts to explain the action of a drug as the result of a chemical combination of some of its groups with other constituent groups or radicals in the complex molecule of the living protoplasm of the cell or tissue upon which it acts. Though one is still a long way from a synthetical construction of a protein molecule, the building up of the polypeptids by Emil Fischer strongly encourages the hope that this giant achievement is a possibility in the not far distant future. A grave obstacle to the acceptance of a purely chemical hypothesis of drug action has hitherto existed in what one may term the bogey of catalysis and cell enzymes. If one could clearly prove that the action of enzymes is to be explained on a purely chemical basis as has been done in the case of the toxin and antitoxin, it must be conceded that the way to a clearer chemical conception of drug action is opened up. It appears impossible to escape the conclusion that the ferment contains a haptophore and as toxophore group, which combine chemically with receptors in the molecule of the antiferment.

**4. The Analysis of Nystagmus.**—A. Abrahams studied the various forms of nystagmus with the aid of a special model of cinematograph. By the cinematography of post-rotation nystagmus he found that the movement persisted for at least 11 seconds. Although movement probably continues for some seconds longer it is not sufficiently defined to be visible in the photograph. During the 11 seconds there occur 44 distinct movements of the right eye towards the inner canthus and the same number of distinct movements to the opposite side. In nystagmus elicited by intrameatal compression in a case of labyrinthine fistula, the analysis of the movements produced showed no indication of any attempt at spring nystagmus (jerk nystagmus or "nystagmus à ressort"), but the nystagmic and reactionary phases are approximated equal in extent and in velocity—pendulum nystagmus. In spontaneous nystagmus of non-vestibular origin the movement is of the undulatory type and the duration is on the whole remarkably constant in both directions. All attempts at the photography of miner's nystagmus were unsuccessful—the oscillations appear to be both too small and too rapid for cinematography. A collection of the observations of many observers upon many forms of nystagmus groups them into the two varieties, "nystagmus à ressort" and undulatory nystagmus, as follows: *Nystagmus à ressort.*—Nystagmus of muscular pareses. Cerebellar and vestibular disturbances. Vertigo (when it depends probably also on vestibular disturbance). Hereditary ataxia of Friedreich. All conditions which reduce the capacity of the posterior cerebral fossa. Certain cases of congenital amblyopia. *Undulatory nystagmus.*—Double complete cataract. Amblyopia. Photophobia. Tabes. In disseminated sclerosis both kinds are seen.

**5. Idiopathic Cerebral Abscess.**—J. Henderson states that in a very large percentage of cases of cerebral abscess the determining cause is easy of recognition, but in the remainder it is either very difficult or quite impossible to assign a cause. Cases in which the etiology is very obscure have been from time to time recorded in medical literature. Oppenheim refers to several such cases, though at the same time he recognizes that septic material circulating in the blood may pass directly to the brain, giving rise to a primary purulent encephalitis. Idiopathic cerebral abscess must be a very rare condition—so much so that Osler states that it need scarcely be considered; but in a case like the one reported by the author, in which there was no cause assignable during life, nor discoverable post mortem, the term "idiopathic" seems to have been quite justifiable.

**2. The Cardiac Sign in Cancer.**—W. Gordon describes this sign as a remarkable diminution of the cardiac dullness in the recumbent posture as determined by digital percussion. In that posture the dullness, in the normal adult, begins above about the third costal cartilage, reaches rightwards as nearly as possible to the midsternal line, and measures across about 3 to 3½ inches at the level of the fifth costal cartilage. On the other hand, in the cancer patient who presents the sign the cardiac dullness in recumbency begins above about the fourth or fifth costal cartilage, has its right margin ½ inch or 1 inch to the left of the midsternal line, and measures across less than 2 inches at the level of the fifth costal cartilage. Often it measures less than 1 inch across. Sometimes there is no cardiac dullness at all. The sign may be explained in three different ways: In some cases of cancer the heart is small, and this reduction in size has been said to account for the reduction of the dullness. This may sometimes partly explain the sign; but by no means always; for often the dullness, though very small in the recumbent position, is normally or even abnormally broad in the erect. If the loss of elasticity, so common in the skin in cases of cancer, affects the lung as well, it is conceivable that ordinary respiration may induce a sort of spurious emphysema and thus diminish the dullness. It is now known that a peculiar form of emphysema does often occur in cancer—Fenwick found it in 28 per cent. of his cases of gastric cancer—and no doubt in many cases this helps to produce the sign. The cardiac sign is often associated with a remarkably soft and toneless pulse, and with very feeble heart sounds. The author sums up the results of his experience as follows: The sign is of practical value. If present in a case in which the presence of cancer is possible, the diagnosis of cancer should only be rejected after most careful consideration. If absent in what may be an early case of cancer, little stress must be laid on its absence. But if absent in what must be, if cancer at all, a late case of it, its absence strengthens considerably the likelihood of the absence of the disease.

**3. Lipodystrophia Progressiva.**—F. Parkes Weber defines this condition as a disease possibly confined to the female sex, and characterized by progressive disappearance of the subcutaneous fat from the face, upper extremities, and trunk, whereas the fat of the lower extremities and gluteal regions remains unaffected or is increased in amount. In some cases, perhaps, the condition is one of pathologically altered distribution of fat rather than of genuine wasting, or possibly merely of relative excess of fat in the lower extremities and buttocks of an otherwise rather thin subject. It is by no means certain that the disorder is always a progressive one. In all probability all degrees of this abnormal fat distribution occur, progressive in some subjects, and arrested or stationary in others, while in yet other cases the condition may probably occur as only a temporary feature in the life-history of a patient or as little more than a slight exaggeration of a normal female sex character.

**4. Chronic Pneumococcal Infection of the Lungs in Children.**—P. L. Sutherland and A. H. Jubb conclude that phthisis is not as common in children as certain recent reports would appear to imply. Many cases of

"phthisis" or "suspected phthisis" in children are really chronic pneumococcal infections of the lungs inducing bronchial and peribronchial lesions. These pneumococcal cases in children form a large percentage of the cases cured or improved in open-air schools. It is extremely likely that such cases in children are treated at tuberculin dispensaries as phthisis in which the tubercle bacilli are not found in the sputum. These pneumococcal infections tend to be chronic and non-fatal, though there is always the liability to tuberculous infection.

5. **Non-Operative Treatment of Tonsils and Adenoids.**—W. Steuart has found that the *x*-rays have a stimulating effect on chronically inflamed adenoid tissue, and enable it to resume its healthy condition. The tonsils do not entirely regain their normal size except in favorable cases, the diminution in size being dependent on the time the organ has been inflamed or on the amount of fibrous tissue that has been formed. The decrease in size is sufficient to dissipate all obstructive symptoms. Conditions dependent on the septic state of the tonsils and adenoids are relieved. Regarding the merits and demerits of the surgical and radiological methods the following points may be raised. It cannot be right to remove tissues that have a definite function, and though this procedure has been necessary in the past it is surely better to restore such tissues to a healthy condition rather than remove them. A small proportion of tonsils owe their enlargement to tubercle, and in these cases it is a matter of risk to resort to surgery on account of the possible dissemination of the disease. The radiological method takes longer, but against this there is no shock to the child and no convalescent period; and as for the sum total of inconvenience the advantage lies with the *x*-rays. The parts affected by operation do not comprise the whole of the inflamed area, whereas by radiation all the pharyngeal lymphoid tissue can be subjected to the influence of the *x*-rays. Recurrences are not at all uncommon after the use of the guillotine.

6. **Lymphatic Gland Extract in the Treatment of Enlarged Tonsils and Adenoids.**—H. T. Ashby states that the mere presence of adenoids does not constitute a disease, and they only become pathological when they hypertrophy and cause trouble. In infancy and childhood the lymphatic structures are at their maximum exactly at the time when enlarged tonsils and adenoids are commonest, and it is one of the functions of the lymphatic tissue to form the lymphocytes. Now it is a peculiar fact that children with enlarged tonsils and adenoids rather have a diminution of lymphocytes in the blood, and there is also an increase in the total number of leucocytes. For this reason it looks as though the enlargement of the tonsils and adenoids were an attempt on the part of Nature to supply the deficiency in the other lymphoid tissue of the body. At the age when enlarged tonsils and adenoids are commonest (2 to 5 years) the lymphocytes are normally beginning to decrease from the high percentage found in infants to the adult standard, and again, the thymus is also decreasing in size. The author believes these two facts support the view that the adenoids and tonsils are an attempt to augment the lymphoid tissue of the body. It is also a common fact that when the enlarged tonsils and adenoids are removed carefully by a competent surgeon before the age of about 5 years they are very liable to recur, so that Nature, as it were, makes a second attempt to raise the amount of lymphoid tissue, or at least supply the body with some secretion from the lymphoid tissue, which it needs at this age. If one could supply these children with lymphoid tissue artificially, there would be no need for the enlarged tonsils and adenoids, and in consequence they would go down, and it is on these lines that the author has been working. Up to the present he has treated about thirty cases of enlarged tonsils and adenoids with lymphatic gland extract, in doses of 5 grains, three times a day. No bad effects have been observed, and nearly all the children have improved in a very satisfactory way; the snoring and noises in breathing have disappeared, and the tonsils have diminished in size.

*May 26, 1913.*

**Achylia Gastrica and Anemia.**—Faber speaks of the importance of this subject and the frequency with which it is discussed. Chronic achylia gastrica is now recognized as a not uncommon condition and within the past few years the author has compiled notes of over 200 cases in his own clinic. Among this material there occurred 22 cases of severe simple anemia, in which hemoglobin ran from 65 to 35. The lowering of the number of erythrocytes, while marked, was not as marked as the reduction in hemoglobin. The index was invariably under 1. The symptoms of achylia were associated with those of anemia. None of the patients died. There remain for consideration 22 cases of achylia with pernicious anemia. The association of the former with the latter is almost constant, due according to some authors to gastric atrophy and to others to toxic gastritis. It appears that achylia may exist for many years before anemia sets in, and the most logical conclusion is that the latter appears when the gastric cells have finally become destroyed. Although this sequence may often be seen it does not explain all cases, for we may have achylia and anemia without structural atrophy. In such cases we find only an intense gastritis which does not involve the glands. This and other finds suggest a toxic component similar to that produced by certain tapeworms which are known to be a frequent cause of anemia. It is of course natural to think of the absorption of hemolytic poisons of some particular origin, and so one asks what part may be played here by bacteria. The only thing absolutely determined is that achylia precedes anemia.

**Treatment of Tabetic Phenomena with Arsenical and Bacterial Preparations.**—Döllken refers only to cure of the clinical phenomena of the disease—although if remedies could be found to dispose of all symptoms this would amount to a complete cure. The measures employed are as follows: salvarsan and a synthetic combination of arsenic and mercury are employed to attack any actual syphilitic component which yet remains accessible to specific treatment. We have recently learned that spirochetes are present in tabes, and if they cannot be controlled by salvarsan, ordinary bactericides may be essayed together with such substances as bind bacterial toxins. As a bactericide the author first tested pyocyanase—a bacteriolytic enyzme. As the exhibition of this substance was attended with disadvantages he began to use a pyocyaneus vaccine. Nineteen patients in the earliest stages of ataxia seemed to improve. That is, the lancinating pains, bladder troubles disappeared, the ataxia vanished and patients were able to resume work. The favorable effects of a tuberculin cure are already well known. Tabes in individual cases has been known to improve during a rabies cure, and after injections of diphtheria antitoxin.

**Arsenical Palsies.**—Obermiller cites the old view that arsenic manifests itself in the brain by convulsions and in the cord by paralyses, and adds that since the introduction of salvarsan, the ancient belief has received no corroboration; in fact, we have ignored it and instead have erected new theories of neurotropism which have led to no definite conclusions. An immense number of citations from toxicologists are then submitted with a consensus which seems to show that arsenicism from the

salvarsan presents no actual differences from arsenicism in general. We see hemorrhagic encephalitis and spinal paralyses, in both luetics and non-luetics. In a word the cerebrospinal accidents following salvarsan represent only arsenicism and should be preventable.

*May 15 and 22, 1913.*

**Pathology and Therapy of Degeneration.**—Hübner delivered a full lecture on this subject in Westphal's clinic. The condition is at present in need of standardization. It is essentially inherited, and the psychical peculiarities of parents and children show a certain correspondence, although actual cumulation of one particular expression in a family is uncommon. The author assumes that alcoholism in the parents is not necessarily directly responsible for a good share of degeneracy in the offspring; for the alcoholic ascendant was invariably himself a degenerate. Again he is conservative about the part played by lues and tuberculosis. Back of all secondary causes is more degeneracy, and degeneracy there must have been long before syphilis and alcoholism existed as we understand these terms today. That is to say, the higher physical stigmata, like cleft palate and cryptorchidism no doubt existed always. The most conspicuous psychical expression suggesting degeneracy in childhood is seen in the various sleep disturbances. Another is seen in the conduct at school—the desire to avoid obligations and to antagonize their teachers—in other words, they rebel against all discipline. They lie and are cruel. With puberty they develop a peculiar vita sexualis, more noticeable in girls who may have no self-restraint at all. In after years the symptoms most in evidence are those comprised under hysteria, psychasthenia, sexual abnormities, obsessions and phobias, and actual psychoses. Under treatment the author only cites educational methods in youth.

**Intranasal Operations for the Cure of Headache.**—Fröse reports a number of cases of headache which he believed due to compression of exostoses, hypertrophies, etc., upon sensory nerve filaments. His conception is best shown by individual cases. Thus a man with swollen face, lacrymation, etc., had complained for four months past of severe headaches. There was an S-shaped curve of the septum and the middle turbinal was similarly bent. Anemization of the nasal chamber did not enlarge the lumen. Submucous resection of the septum caused some improvement in the headaches, but not enough to constitute a good result. The two middle turbinals were then subjected to resection and the headaches permanently disappeared. A number of similar cases are described.

**Sociological Sterilization of the Insane.**—Friedel adds some cases to a certain European material; these are not cases in which sterilization was actually effected but where it was unquestionably indicated but refused. In one instance of an imbecile girl living at home her parents refused the intervention, while in another asylum control or segregation filled the indication for sterilization. Nowhere in Germany are laws for the latter yet available, although the practice is under way in parts of Switzerland. The point made by the author is the enormous damage done before these cases come to the attention of alienists. The girls give birth to several children destined to become burdens to the community. They seduce young boys and in one case a girl submitted to sixteen boys in succession, and evidently took the initiative. An immense amount of gonorrhea is diffused through the community. It is, of course, hoped that the high degree of salacity will be much diminished by the sterilization. This at least is the case with the male after vasectomy. The danger from the imbecile girl is that she constantly follows men and boys about and thus greatly multiplies opportunities. Segregation will very likely prove to be the only resource for the girls and women of this type.

**Bacteriological Studies in Nurslings with Intestinal Diseases.**—Gildemeister and Baerthlein sum up their finds as follows: in a high percentage of these nurslings bacteria were present which belong to the toxin-poor dysenteric group, and appear to be pathogenic at times—for example a change of diet may activate them—while in other cases the activation is spontaneous, due perhaps to the quantitative factor. We know nothing as to the conditions which permit the germs to multiply. In but a small per cent. of cases have the paratyphus B. and Gaertner's *B. enteritidis* been associated, and it is impossible to state the causes of this association or to what extent the disease picture was influenced by their presence, but the authors are inclined to believe that these germs determine the character of certain diseases. In the nursling feces we frequently encounter the *B. proteus*, *B. pyocyaneus*, and *B. coli* in several forms, both alone and in association with dysentery and paratyphus germs. It has not yet been determined to what extent all these organisms are pathogenic.

**Case of Rare Disturbance of Potence.**—Lissmann relates a case which he believes to be unique. A healthy clergyman married at the age of 32. His vita sexualis had been very simple. He had masturbated as a boy not over three times. After that until his marriage he had occasional nocturnal pollutions with erotic dreams and orgasms. On and after his wedding night he had impotentia coeundi, followed later by normal erection and intromission, but without ejaculation. It was necessary in order that his semen be examined to obtain the latter by masturbation, which was easily effected, and the spermatozoids were found to be normal. Nevertheless for many years the man could not effect an emission. Both the clergyman and his wife had an ardent desire for children which appeared to cause a psychic inhibition of ejaculation. The best authorities in Munich were consulted. Absolutely no reason was found for aspermatism, although numerous theories could be supplied, such as insufficiency of the ejaculatory center as a result of years of disuse. Yohmibin given even by epidural injection, did no more than stimulate the erections. Coitus was performed in the inverted posture, but nothing could rouse the center of ejaculation. Since the patient had been found able to ejaculate with masturbation an attempt was made to employ the latter up to the moment of ejaculation and then insert the penis into the vagina. Although this stratagem was successful conception did not result. As a last resort artificial impregnation was advised.

**Striking Uremic Phenomena.**—Engelen reports the case of a woman aged 38 admitted to a hospital for "apoplexy and uremia." She had had nephritis for five years, and in the meantime convulsive attacks attributed to hysteria. Ordinarily she felt perfectly well, although never free from uremia. The condition on admission was extremely complicated, suggesting hysteria as the simpler solution. She had bronchitis with fever, however. The motor phenomena were unilateral and their nature, together with the state of the psyche, was strongly suggestive of hysteria. Nevertheless the patient soon passed into fatal coma. The author terms the case one of toxic (uremic) hysteria. Uremia alone can cause an entire train of psychic phenomena. There must also have been a focal lesion in the left pyramidal tract.

---

**Cerebrospinal Fluid in Tuberculous Meningitis.**—H. Roger calls attention to the following chemical changes characteristic of the cerebrospinal fluid in tuberculous meningitis in the child: hypochloruria, diminution in the ash, a moderate hyperalbuminosis, and a marked reduction in the amount of glucose.—*Le Progrès Médical.*

# Insurance Medicine.

## SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

### ELEMENTARY PRINCIPLES OF LIFE INSURANCE.

*Sources of the Surplus*:—The difference between the actual cost of insurance and the amount of premiums paid with the interest thereon creates a surplus or excess fund, out of which the so-called dividends are taken for distribution to the policyholders. This fund is derived from the following sources:

1. Surplus derived from a Favorable Mortality. In computing the premiums it was assumed that the actual mortality would correspond with the mortality table. In practice, however, it would be impossible to construct an infallible table and as the actual rate will differ somewhat from the tabular rate, it is imperative, for the sake of security, for any deviation to be in the favor of the company; that is, for the rate to be lower rather than higher than that indicated in the table. As a result of careful selection in well-managed companies, some of the policyholders do outlive the period indicated in the table. The deaths of those who live longer than expected will occur ultimately, but the extension of their lives implies the receipt of a larger number of premiums and a longer time for interest on the funds to accumulate, the gains from both sources going into the surplus. A poor selection of risks, on the other hand, with the consequent writing of a lower grade of risks would probably turn these gains into an irretrievable loss.

Experience teaches that a judicious selection of risks after competent examinations results in a mortality considerably less than the average for the same age and that a large influx of new business tends to produce a favorable rate of mortality. For instance, the mortality in the first year of insurance is rarely as high as 50 per cent. of the tabular rate. This percentage gradually diminishes but remains less than the tabular rate for many years longer. It is commonly assumed that the benefit of selection lasts only about five years and this is true to a large extent. Nevertheless, the influence of selection will continue much longer if due consideration is given to such questions as family history, overweight, rheumatism, gout, syphilis, and other conditions which are apt to affect the risks in later life.

The statements of new companies should show the benefit from this early low mortality and the public might be misled by a comparison of their rates with those of the older companies which inevitably experience a higher mortality due to deaths among policyholders of long standing. This advantage to the new companies is offset to a large degree by the increased expense of inaugurating and writing new business and it should furthermore be remembered that the new companies will eventually have the same obligations to meet and that they still have to encounter the vicissitudes and chances of failure incidental to all corporations in their infancy. It is problematical then as to whether or not the low rate of mortality reported by these companies will help materially in forming a surplus.

2. Surplus derived from the Loading. The loading is the amount added to the net premium to provide for the expense of managing the business and for contingencies. The percentage of loading is determined by each company, but competition compels the adoption of a rate as low as possible. Still, the rate must be larger than actually needed and as the excess is added to the surplus, the policy holders are compensated for the additional expense and, at the same time, the security of their interests is made more certain.

3. Surplus earned from a High Interest Rate. The maximum rate of interest that may be assumed by the companies is prescribed by the laws of the several States and varies from 3½ to 4½ per cent. In New York, Massachusetts and a few other States the specified legal standard calls for 3½ per cent., so that a company whose premiums are computed on a 4 per cent. basis must, in order to do business in those States, submit to a valuation of the higher standard of 3½ per cent. Many companies have adjusted their premiums on the still more conservative basis of 3 per cent. The gains and savings from interest will vary according to the reserve basis, the gain from interest being naturally greater on a 3 than on a 3½ or 4 per cent. reserve. The companies should earn between 4 and 4½ per cent. on conservative investments, the difference between this and their assumed rate going to the surplus.

4. Surplus derived from Lapses. Lapses are not a desirable source of profit to a company on account of what is called "Adverse Selection against the company." Nearly all policyholders who lapse are in good health, whereas those whose health has become impaired cling to their policies.

At the end of the third year and thereafter the lapsing policy possesses a "surrender value" made up of a large part of its own reserve which may be withdrawn, or applied to the purchase of a paid-up policy or extended insurance. The extended or continued insurance goes into force automatically, in the event of default in payment of the premium, if the other options are not chosen by the policyholder, and remains as term insurance for a definite period set forth in the policy. The remaining small part of the reserve is retained by the companies as a "surrender charge," but there is grave doubt as to the adequacy of this charge as a compensation to the companies for the adverse selection in lapses.

Surrender values are not granted until the policies have been in force more than two years. Little or nothing is gained by this restriction, however, as the forfeited reserves do not make up for the expense in replacing lapsed policies on the books.

It may be regarded then as a general rule that while some profit may be derived in some cases from lapses, they can not be regarded as an appreciable source of surplus.

---

**Effects of Furfural.**—J. T. J. Battle points out that furfural, which is generated by the combustion of tobacco, has a direct effect upon the suprarenal glands, causing an increased flow of their secretions, which in turn first raise the blood pressure, but later decrease it. This explains why a smoker becomes an excessive one. The lowered blood pressure needs constant stimulation. Overstimulation of any organ causes in time a deleterious effect. So the age of beginning smoking should be postponed as long as possible. Tobacco undoubtedly tends to shorten life.—Medical Section, American Life Convention, Hot Springs, February, 1913.

# Book Reviews.

A Clinical System of Tuberculosis, Describing All Forms of the Disease. By Dr. B. Bandelier and Dr. O. Roepke. Translated from the German by Dr. G. Bertram Hunt. $6.00 net. New York: Wm. Wood & Co., 1913.

The authors of the Clinical System of Tuberculosis have already been introduced to the English-speaking public by Dr. Morland's translation of their excellent book, "Tuberculin in Diagnosis and Treatment." The book before us has many interesting features, not the least of which is the conciseness and yet completeness with which it treats of all the clinical phases of tuberculosis. The etiology and pathology receive careful consideration, and while not offering anything new the very excellent colored illustrations give to the student of pathology a very good idea of the changes in the tissues brought about by Koch's bacillus. The symptomatology of the various organs of the body when afflicted with tuberculosis is on the whole excellent. If any criticism of this portion is justified it is that the authors, perhaps inadvertently, neglected almost completely the works of any besides those which originated in the fatherland. Thus the very excellent and classic work of Grancher of Paris on physical diagnosis of the lung does not receive the slightest notice. Important works of English and American authors are likewise ignored in the text and even in the bibliography.

As enthusiastic students of tuberculin therapy the authors devote considerable space to this culture product as a remedial and diagnostic agent. It is pleasing to note that they absolutely reject the conjunctival test as not only distinctly dangerous but also as markedly uncertain and unreliable since the positive reaction generally only indicates that there is a tuberculous focus somewhere in the body, but it is silent as to the site, activity, or inactivity. Refreshing also is the caution which the authors express concerning the use of tuberculin as a remedial agent when they say: "Whoever takes up tuberculin treatment must first master the general details of this valuable remedy and must have the desire and ability to make himself familiar with the various irregularities which may occur." The other well-known remedial agents, medicinal and climatic are enumerated. The aero-, helio-, and hydrotherapy receive their due share, and all of the excellent results obtained at Leysin from exposure to direct sunrays in the surgical forms of tuberculosis are mentioned. Interesting is also the reference to radium as one of the newer means of curing surgical tuberculosis, especially abscesses and fistulæ. Somewhat surprising is the omission of the value of seacoast climate in the treatment of joint tuberculosis, particularly in children.

The translator has done his work well, with the exception of one very unpleasant, if not philologically wrong use of the adjective "tubercular" instead of *tuberculous*. As an example of the inaccuracy of his use of the word tubercular we would refer only to one instance where he speaks of a "tubercular neuritis." It is well known that in the tubercular type of leprosy, where there is a pathological pinheadlike conformation, we may have also a neuritis accompanying it, yet no one would think of considering this tubercular neuritis as having anything to do with the tuberculous neuritis primarily due to the invasion of Koch's tubercle bacillus. Aside from this little criticism the book, which is beautifully gotten up and substantially bound, may be considered as one of the best of its kind and a good guide to the general practitioner as well as to the special student. It is a splendid résumé of what we know up to date of the etiology, pathology, and therapy of the various forms of tuberculosis.

The Fitness of the Environment. An Inquiry into the Biological Significance of the Properties of Matter. By Lawrence J. Henderson, Assistant Professor of Biological Chemistry in Harvard University. In Part Delivered as Lectures in the Lowell Institute, February, 1913. Price $1.50 net. New York: The Macmillan Company, 1913.

All the departments of science are touched upon in this little volume. The subject is presented in a scholarly way and an advanced doctrine is expressed in the light of the recent growth of the science of physical chemistry. The mutual relationship between the organism and the environment was recognized by Darwin and his followers. But the author desires to prove that "fitness of environment is quite as essential a component as the fitness which arises in the process of organic evolution; and in fundamental characteristics the actual environment is the fittest possible abode of life." The applications of the new physical chemistry to physiology began only about fifteen years ago. Maly's important observations on the phenomena of the diffusion and dialysis of phosphates and the behavior of solutions containing carbonic acid, for example, were not definitely explainable until the later theory of ionization shed its light. An understanding of the peculiar conditions of equilibrium between acids and bases in blood and protoplasm is of recent date. The automatic regulation of neutrality possessed by phosphoric acid and carbonic acid is a fact of great importance and of recent knowledge. The author has collected the various chemical and physical facts relating to the general and special properties of matter, etc., in his book and interprets them in their biological relations and in their reciprocal character between organism and environment. The task is one of great biological interest. The author employs a logical rather than a descriptive method, from necessity, he says, in the development of his argument. But he has condensed his evidence in four chapters on which he rests his case. These four chapters comprise: Water, its thermal properties and action upon other substances; carbonic acid, its solubility and acidity; the ocean, its condition, effect on circulation of water, and as environment; and the chemistry of the three elements, C, H, and O. The remaining four chapters of the book are devoted to the purpose and outcome of the investigation. The book is intended for the biologist, and will be of interest to the scientific physician.

A Handbook of Surgery for Dental and Junior Medical Students. By Arthur S. Underwood, M.R.C.S., Eng., L.D.S., Eng., late examiner Royal College of Surgeons, Eng., etc., etc., and Bayford Underwood, M.B., B.S., London; L.R.C.P., M.R.C.S., England. Price $1.50. New York: Wm. Wood & Co., 1913.

This is a very readable condensed surgery quite elementary, even though somewhat comprehensive. There is little if anything new and as the authors state in the preface, considerable has been borrowed from Rose and Carless and other textbooks on the subject. There are very few illustrations. After a cursory view of bacteriology the authors enter upon a discussion of asepsis and antisepsis, followed by the usual chapters on inflammation, ulceration, gangrene wounds, etc. Then follow sections dealing with arteritis, diseases of the nerves (tic, herpes zoster) and of the lymphatics (elephantiasis macroglossia, etc.) and diseases of bones and joints. Under the latter the author makes two broad statements, viz., a single joint inflammation is almost always gonorrheal and "rheumatic" joints in children are more often osteomyelitis. The book is quite general but ought to be of service to those requiring only an elementary knowledge of surgery.

Heredity, Evolution, and Vitalism. By Ronald Campbell Macafie, M.A., M.B., C.M. Price $2.50. New York: Wm. Wood & Co., 1912.

The philosophy of science is one of the predominant notes of this book. The author discusses first the phylogeny of man as a recapitulation of evolution. Weismann's theory of determinants is touched upon and also Mendel's classical experiments. Determination of sex is quite fully discussed with reference to bees from fertilized and unfertilized eggs. In this connection the idea seems quite new that the male offspring is more metabolic, as is shown by the preponderance of males in high dry altitudes where oxidation is more active. The author refutes Darwin's statement, "*natura non facit saltum*," by referring to new species developed without transition and puts special creation in the place of Darwin's denial of the necessity of the supernatural. As to spontaneous life he says vital force is contingently teleological and creative.

Chloride of Lime in Sanitation. By Albert H. Hooker, Technical Director, Hooker Electrochemical Company. New York: John Wiley & Sons, 1913.

The Hooker Electrochemical Company manufactures chloride of lime and set about to collect all data in regard to the use of this substance in sanitation. The result written in book form and presented here is exceedingly satisfactory. The applicability of chloride of lime for the disinfection of water, sewage, garbage, streets, etc., is demonstrated and its cheapness and reliability extolled. About two-thirds of the volume is taken up with abstracts and references which number over four hundred, thus furnishing easy access to all the literature on the subject. In the text, the argument is very forcibly presented, and if the publication largely increases the use of chloride of lime in sanitation it will have been of benefit not only to the makers but also to even a greater degree to the users.

# Society Reports.

## AMERICAN MEDICAL ASSOCIATION.

*Sixty-fourth Annual Meeting, Held at Minneapolis, Minn., June 16, 17, 18, 19 and 20, 1913.*

(Special Report by Telegraph to the MEDICAL RECORD.)

### HOUSE OF DELEGATES.

*Monday, June 16—First Day.*

THE PRESIDENT, DR. ABRAHAM JACOBI OF NEW YORK, IN THE CHAIR.

**President's Address.**—Dr. ABRAHAM JACOBI said that hitherto it had not been the custom of the president of the American Medical Association to consider the strictly scientific or technical problems that affected the association, but to leave these with the sections. He would take the liberty to suggest that the papers presented be fewer in number, as they did not all benefit ten thousand listeners. Ample discussion would be more profitable than voluminous papers. All extemporaneous remarks enlisted sympathy and not only drew audiences but held them. All successful medical societies, as well as other organizations, made the office of secretary more or less permanent, and it seemed desirable to him that a change in this organization with respect to the term of office of the secretaries of sections be made. Such a step would add to the character of the section work. It was one of the functions of the president of the association to act as teacher and guide in the political, educational and economic interests of the profession and they were responsible to those of the profession less instructed and less capable than themselves. At present the influence of the president was trifling and far from permanent. His duties were few. It was not proper that he should suggest changes resulting in an extension of the duties of his office while he was holding that office lest he be suspected of adding to his own prerogatives.

One should never be the prey of political push. Thus the office demanded few duties but profound silence. He had asked for invitations to attend the meetings of councils, committees, etc. These had always been granted and he had been received cordially but it seemed to him that the president of the association should be chairman of some of the conferences and have a deciding vote in others. He should have the right of speech in all. Dr. Jacobi said he would like to address the absentees. It was largely their neglect of duty that was responsible for the accusations of conspiracy on the part of those active in the conduct of the affairs of the association. The indifference of those at home who shirked their duties did not help to make willing servants of their delegates. Complaint had been made that the activities of the American Medical Association were at a standstill; he had received many letters objecting to the methods of the association in conducting its business and asking for a more open procedure. There was no reason in these complaints, for the House of Delegates had great responsibilities. It might be suggested that the house should convene two or three days before the scientific meeting when there would be more time for due deliberation. Those of scientific mind and heart wished to fulfill all obligations and many declined the duties of delegates because they wished to devote their time to the section work. The various States should select delegates for their personality, and if they did this there would be fewer complaints of the autocracy of the House of Delegates and less fault found with the method of conducting business.

Dr. Jacobi then read a letter from the American Institute of Homeopathy asking that a committee of five from the American Medical Association be appointed to confer with a similar committee from the aforenamed organization for the purpose of making a scientific investigation of the formula, *similia similibus curantur*. The letter further suggested that such an investigation be conducted under the auspices of some institution like the Rockefeller or the McCormick Institutes. Such an investigation would be of the utmost value to both schools of medicine. If the theory of homeopathy were found to be true it would add materially to the armamentarium of the regular physician, and if it were disproved then the last barrier to medical unity would be swept away.

**Report of the Secretary.**—Dr. ALEXANDER R. CRAIG of Chicago submitted this report in which he stated that the membership of the American Medical Association on May 1, 1912, was 34,283. During the past year a total of 2,421 names had been deducted from the membership list. There had been added 6,051 names to the membership roll of which 4,695 were transferred from the subscription list. The membership of the American Medical Association on May 1, 1913, was 37,913, a net increase for the year of 3,630. As was readily seen this gain in members was due largely to circularizing subscribers to the Journal who were eligible, urging them to become members. This increase under normal conditions would have been distributed throughout the years during which the question of postage on journals mailed to members was unsettled. The secretary also presented a petition to create a section on gastroenterology and proctology. He submitted a petition from the Medical Association of Porto Rico addressed to the House of Delegates of the American Medical Association praying that the Medical Association of Porto Rico be accepted as a constituent branch of the American Medical Asssociation.

**Report of the Board of Trustees.**—Dr. W. W. GRANT of Denver submitted this report. He said that it was a pleasure to report favorable and in the main very satisfactory progress in association work during the past year. The establishment of a surgical journal was still under consideration by a committee of the Board of Trustees. The Council on Health and Public Instruction was doing an educational work of the greatest interest and importance in public health matters. Its cooperation with clubs and non-medical organizations in creating a public interest and demand for medical lectures and information on public health matters was worthy of the commendation and endorsement of the profession. The Committee on Medical Education had continued its active labors in behalf of fewer and better schools, better standards of admission, more scientific instruction, and a higher class of men for the practice of medicine and surgery. The board had last year passed a resolution limiting the length of papers to four pages of the Journal and the discussions of each speaker to five hundred words, unless otherwise ordered by the publication committee. The conditions, however, during the past year had been aggravated by the increased number of sections. For instance, in 1908 there were 294 papers read before the sections; in 1910, 315; in 1912, 411. This large number of papers made it impossible to complete their publication within a reasonable length of time, which was a serious disadvantage both to the Journal and the authors. Furthermore in the endeavor to crowd section papers through little space was left for voluntary articles and of course it was realized that the success of the Journal depended much on the excellent work of the association, especially as far as finances were concerned. Therefore the board suggested that the House of Delegates give the subject serious consideration before it established more sections. The large number of sections made it increasingly difficult to find satisfactory places of meeting and there was danger of making the section work top-heavy and of the duplication of subjects by two or more sections. They had therefore adopted a resolution at their February meeting recommending that the number of papers to be read in any section at the annual meeting should not exceed thirty and that the by-laws be changed in accordance with this resolution. The board further recommended that the retiring chairman should be the one to pass on and approve or disapprove of the publication of the papers read and that the by-laws be modified to meet this recommendation. The board recommended that the House of Delegates take some action either in the form of resolutions or otherwise urging the sections to consider the advisability of making the secretaryship a more permanent office than it was now. The board believed that this recommendation was of vital importance. However, the Board of Trustees considered the advisability of appointing a committee to assist the State journals that were conducted in accordance with reasonable rules as to plain honesty in their advertising and reading pages, in securing honest advertisement on a reasonable percentage basis. In line with this recommendation a plan was being worked out to establish a cooperative medical advertising bureau in the association headquarters with the object of furthering the interests of the various State journals that complied with the standard regarding advertising. This would mean the appropriation of a certain amount of money, as the board expected to be able to adopt a plan at the present meeting.

Relative to the action of the House of Delegates recommending that the Board of Trustees be directed to amend the charter so as to provide that the president, the secretary, and the editor of the Journal should be ex-officio members of the Board of Trustees without the right to vote, and that the secretary of the association should be ex-officio secretary of the Board of Trustees, the attorneys of the association expressed the opinion that this

would be invalid under the laws of Illinois. The circulation of the *Archives of Internal Medicine* was increasing as much as could be expected, though the loss on this publication last year was $500. The circulation of the *American Journal of Diseases of Children* was now approximately 1,900, the loss on this publication having been about $300 last year.

With reference to the work of the Council on Pharmacy and Chemistry it was emphasized that the Council was now doing more practical and constructive work than ever. Especially of this character was the clinical and research work being done under the direction of the Committee on Therapeutic Research. The board had thus far appropriated $3,500 for this work, believing that it should be encouraged in an endorsement of the Council's broader aims toward the improvement of conditions. It was mentioned that it had now issued, in preliminary form, a publication known as "Useful Remedies." This contained a limited list of drugs and when issued in complete form the book would include a description of the action, use, and dosage of the drugs mentioned. The main object of the book was to furnish a list of important drugs that should be used as a basis of teaching in medical schools, and also as a basis on which State Boards of Examiners should examine applicants for license to practice. Although issued only in a tentative form, this book had already been adopted by several schools and also by various examining boards. As a direct result of the work of the Council on Pharmacy and Chemistry, a similar body had been created in Germany. One of the principal men in this body, and the one really responsible for it, was Professor Heubner, of the University of Göttingen, and editor of the *Therapeutische Monatshefte*. The Council asked the Board of Trustees to elect Professor Heubner a corresponding member of the Council on Pharmacy and Chemistry. This the board gladly did, especially because of the great work he had done in bringing about better conditions in Germany.

The work of the Council on Pharmacy and Chemistry was not as cordially supported as it should be by the leaders in the profession, surgeons as well as clinicians, but the rank and file of the profession did appreciate the work and were cooperating. For instance, a large number of physicians dispensed their own drugs, and it was charged that many of such physicians obtained their drugs from so-called "physicians'" supply houses. It was also charged that the official drugs furnished by these supply houses were not standard. Their chemists had about completed an investigation covering many of the products put out by these firms, and the report of this work would soon be published. The work of enlightening the public in regard to fraudulent "patent medicines" and quackery had been broadened in its scope and was producing encouraging results. The number of inquiries from laymen had increased enormously. Many lay societies carrying on antituberculosis campaigns had used the information published in the Journal on "Consumption Cure" frauds and had distributed numbers of their pamphlets in their employees' libraries. Newspapers and magazines were continually writing for information in regard to advertisers. A second edition of the book "Nostrums and Quackery" had been issued, the first edition of 10,000 copies having been exhausted in less than a year.

In accordance with the authorization they, the House of Delegates, secured a bronze bust of Dr. N. S. Davis, and placed it in what was originally called the library, but which by definite action on the part of the Board was now designated as the Davis Memorial Room. The balance of the fund, $3,299.43, was made a permanent fund to be used in any appropriate way, other than the purchase of books, in furnishing and maintaining the Davis Memorial Room in the new building. The Board suggested that the Davis Memorial Room would make an excellent repository for articles of historical interest to the medical profession and to medicine in this country, such as medallions, portraits of prominent men, *Festschrifts,* memorial volumes, etc. Dr. Grant submitted reports from the subscription department of the Journal showing an average weekly circulation of 57,204 and the treasurer's report showed a net income for the year of $39,147, and the total value of the property and plant of the association as $345,613.

**Report of Judicial Council.**—Dr. ALEXANDER LAMBERT of New York presented this report, in which he discussed the matter of membership in the American Medical Association and the relation of this membership to the constituent State and territorial bodies. Membership in any county society of any constituent body should legally, and did, constitute membership in the State body in the State to which the county belonged, and to the national body. Any physician, therefore, joining a county medical society of a constituent State or territorial body thus logically became a member of the American Medical Association. In this membership were some who were content to remain on this footing, but there were others who desired to go further and in this desire were willing to tax themselves by a definite annual fee by which they might maintain the scientific work and the scientific sessions of the American Medical Association, its Journal, and its manifold activities for the benefit of themselves, the other members of the American Medical Association, and the profession at large throughout the United States. These members supporting the scientific work of the American Medical Association, it seemed wise to designate by some special appellation, and this was best fulfilled by the term "Fellows of the American Medical Association." With this explanation of the meaning of the differences between membership and fellowship the judicial council recommended to the House of Delegates that the by-laws be amended to indicate this difference in membership and fellowship in the association.

The Judicial Council had expressed to Dr. J. W. Barrett, of Melbourne, Australia, its appreciation of the invitation he extended on behalf of the Trustees of the Congress and the University of Melbourne to the members of the American Medical Association to attend the Australian Medical Congress to be held in Auckland, New Zealand, in 1914. Members who were able to accept this invitation must leave in January, 1914, the trip requiring three months. Members who desired to make this trip would be furnished with letters of introduction to the New Zealand Medical Association and the Australian Medical Society announcing their membership in the American Medical Association. Literature concerning New Zealand and the trip, sent from Auckland, was in the hands of the secretary of the association.

With reference to a resolution offered at the last meeting of the House of Delegates that a Speaker should be elected who should preside during the twelve months and until his successor should be elected, the Judicial Council considered that this resolution brought up two questions: First, whether or not a Speaker should be elected to preside over the House of Delegates, and, second, whether this officer should be elected by each House of Delegates to preside over its sessions or whether any given House of Delegates should elect a presiding officer for a succeeding house without this succeeding house having any say in the matter. The Judicial Council believed that it should not decide these questions. It, therefore, made the following recommendations: That the House of Delegates should choose a time and an hour at this meeting in which it should sit as a committee of the whole to consider and decide these questions for itself.

With reference to fee-splitting the Judicial Council reported that a circular was sent to each president and to each secretary of each county society in every State in the United States, and various sections of the country were further apportioned off to the members of the Judicial Council who sent throughout their sections personal letters, containing these circulars, to various members of the profession whom the members of the Judicial Council knew to be prominent in their sections and who would be conversant with the public opinion and the practices of the various members of the profession in their communities. Some six thousand circulars were thus sent out and the replies received amounted to just over 50 per cent. of the circulars sent. It might be justly said to be a report founded on the representative opinion of the members of the American Medical Association. From the statistics thus gathered it was evident that in the matter of secret splitting of fees, while the existence of the practice could not be denied in any State, the degree of its prevalence varied greatly in different sections of the United States, and the opinion of the local profession for or against it also varied in different regions. In the New England States the practice was not prevalent, though it existed to a slight degree in them all, being most prevalent in and toward the larger cities of Massachusetts and in that part of Connecticut that was near New York. In New York State the practice varied, some counties being nearly free of the evil, other counties and the large cities being filled with it. In New York City, with its crowded population and with its large proportion of foreigners in some sections of the city, among certain groups of men it was without doubt the rule rather than the exception. It was interesting to note that in the replies given, stating whether or not secret fee-splitting was justifiable there were 77.3 per cent. who answered in the negative, 13.4 per cent. who answered in the affirmative, and 9.3 per cent. who were doubtful. It was interesting to note the rea-

sons given for this secret fee-splitting, as a justification, in the statistics which formed the basis of this report. One of the commonest reasons was that it was justifiable because of the disproportionate fee between the amount paid the surgeon and the amount paid the physician who had made the diagnosis and referred the patient to the surgeon. This was on the basis that a wrong had been done the physician because his services were not as well paid as those of the surgeon. But two wrongs never yet made a right and the further wrongdoing of taking a patient to a surgeon because the latter split the most generously did not remedy or make up an injustice, however great this had been to the physician.

This report also condemned the taking of a commission from a commercial house furnishing an instrument or appliance to a patient and the taking of rebates from hospitals and sanatoria by those sending patients to such institutions. There was no reason in law or morals why a physician should not enter into a contract with an individual, firm, or corporation provided that the contract was an honorable one and did not interfere with the rights of others.

In the mater of lodge practice and fraternal and benevolent societies another situation arose, namely, the question of health insurance. Medical attendance in the lodge and fraternal benevolent associations was a part of the inducement offered members of these associations. There was a point in wage earnings at which these lodge medical services were not economic necessities, but on the other hand there was a point in wage earnings at which the ratio of fixed charges to total income was such that these fraternal societies did become an economic necessity in the sense of health insurance. The late Dr. Bristow, in an address before the New York Academy of Medicine, strongly emphasized this point of view. He further showed that in the United States the annual income of adult males was in 90 per cent. less than $800; in 75 per cent. less than $600, and in fully 50 per cent. less than $500, with 20 per cent. earning as low as $200 per annum. On the other hand, the result on the medical profession of this economic situation was that hardly more than 10 per cent. of the physicians in the United States were able to earn a comfortable income. The medical profession found that an adequate medical education required of students a constantly increasing length of time and of money for its attainment. It was the most costly of all the learned professions, and with the living expenses constantly increasing and with the physicians' opportunities of earning a livelihood from the general population constantly diminishing, and further with the profession devoted to self-immolation by its constantly increasing development of preventive medicine and sanitation, they were forced to consider the situation as one produced by economic forces and that lodge practice under certain circumstances was one of health insurance that must be accepted and controlled and not condemned and shunned. Fee-splitting could be best remedied by the profession announcing that it demanded publicity in all transactions between patients and the members of the profession and that it refused to sanction the retention on the roster of any of its organizations of the names of those who were proven guilty of these practices. The physician had himself to blame who failed to put a just appraisal on his services and to demand a just reward for them and who, through failure of endeavor to collect his just deserts, found himself unappreciated.

The replies received by the Judicial Council on the matter of contracts in mines and railroads and factories showed that in some states the contracts were just and that the recompense to the physician was in ratio to services rendered and was adequate in amount for such services. On the other hand, there were other replies which showed the reverse. The Judicial Council believed the remedy for these evils resided in the county societies, that these societies should use their influence and power not to condemn the physician who must take the contract by ostracizing him, but to prevent underbidding for these contracts below what would give a fair reward for medical services rendered. So, too, in the matter of lodge practice the Judicial Council believed it to be the duty of the local county societies to endeavor to reform and not alone to condemn the abuses of lodge practice.

The Judicial Council, therefore, recommended for adoption by the House of Delegates the following resolutions:

*Resolved*, That any member of the American Medical Association found guilty of secret fee-splitting or of giving or receiving commissions shall cease to be a member of the American Medical Association.

*Resolved*, That the House of Delegates of the American Medical Association recommends to each constituent body that it endeavor through the action of its various county societies to reform the various abuses of lodge practice in their separate communities in order that the lodges may give an adequate service to their members and an honorable remuneration to the medical men.

**Report of the Council on Health and Public Instruction.**—Dr. Henry B. Favell of Chicago presented this report in which he stated that the press bulletin had been continued throughout the past year, a weekly bulletin being prepared and mailed to approximately 5,000 newspapers and publications. During the year from June 1, 1912, to June 1, 1913, forty-four press bulletins had been issued, with an average circulation of 4,763. The effect of this bulletin on the newspapers of the country was apparent. Not only were the items contained in the bulletin more generally used than in previous years, but there had been a marked change in attitude of the press toward the medical profession and the association. Editorials criticising physicians as a class were by no means as common as they were in previous years, while there was an increase in the number of newspapers that used the press bulletin material regularly and as texts for editorials. Speakers had been furnished for 213 meetings held in the seven months, from November 1, 1912, to June 1, 1913. Many requests had been denied, either because the invitation came from a single organization or because the town was too small, and the audience offered would justify the expenditure. The revision of the list of speakers and the preparation of an announcement for the coming season was now being carried on. In the light of the experience of the past seven months the most promising fields for this work seemed to be women's clubs, normal schools, colleges, and other educational institutions and Chautauquas. Teachers' institutes and farmers' institutes, alliances and granges were not included in the plans for the past year owing to the difficulty experienced in securing a complete list of these organizations. They could be included in plans for the coming year. The council recommended that each State which had not already done so be asked to establish a standing committee on public education, either as a separate committee or in conjunction with other duties, and that this committee have oversight of the work of furnishing speakers for the State, calling on the Speakers' Bureau of the American Medical Association to furnish speakers from a distance for the larger and more important meetings. By such a division of work the activities of the association in this direction could be greatly extended. Each State committee could call on the Speakers' Bureau of the American Medical Association to furnish speakers for from five to ten meetings in each State during the year. The organization of a bureau for loaning lantern slides to speakers of local societies and others had been begun, but had not yet sufficiently advanced to render a definite report possible at this time. The Council had called a conference of the various organizations interested in public health work, about fifty organizations having been invited which convened in New York April 12, 1913. After exhaustive discussion of the situation in which the need of better organization and coordination was generally admitted, the conference adopted a resolution offered by Prof. Irving Fisher, authorizing the chairman to appoint a committee of fifteen, to consider the entire question of public health activities and the ways in which they could be improved and to report its findings with definite recommendations to a subsequent meeting of the conference. It was hoped that this movement might result in better coordination of the organized efforts for the conservation of life and health. The work of establishing a medicolegal bureau was progressing. The collection of laws on public health topics had been completed and the bureau had undertaken the preparation of a series of model laws.

During the fall and winter legislators had met in forty-two States. The number of bills bearing on public health matters had probably been unprecedented. As nearly as could be estimated between 700 and 800 bills on health or related subjects had been introduced in the different legislatures. A considerable portion of the time and efforts of the council during the past year had been devoted to an effort to bring about harmonious cooperation between the council itself, the special committee on national health organization, and the committee of one hundred in order that the definite program might be adopted by which concerted action for national health might be possible. Two days' conference resulted in the appointment of a special committee to call on President Wilson and urge on him the importance of establishing a national Department of Health and a White House conference on vital resources.

A committee was also appointed to confer with Senator Owen with a view to revising the present Senate Bill No. 1 The conference also endorsed the program drafted by Prof. Irving Fisher and unanimously adopted after exhaustive discussion, which requested that President Wilson should call a White House conference on public health next fall somewhat similar to the Governors' conference on conservation called by President Roosevelt, the object of this conference being to promote the success of the President's policy and if necessary to aid in framing these policies; that at the next regular session the President should send a special message favoring public health legislation or else should emphasize it in his regular annual message; that the President should select for the position of First Assistant Secretary of the Treasury some one interested in public health; and that in the next regular session they should support the President in securing such public health legislation as he decided to recommend.

The report of the Council on Health and Public Instruction included reports from subcommittees on the prevention of blindness due to accidents, on trachoma, on wood alcohol, etc., on visual standards for pilots, on resuscitation from electric shock, on the protection of medical research, on cooperation with the National Education Association for public health work among women, and on the revision of the model law on vital statistics.

**On the Uniform Regulation of Membership.**—Dr. Thomas McDavitt of St. Paul made this report which contained the following resolutions: (1) That this conference endorse the plan of having the fiscal year coincide with the calendar year in all parts of the organization; that secretaries of all State associations which have not already adopted this provision bring this matter to the attention of their associations and recommend its adoption. (2) That the constituent State associations adopt provisions making dues in county societies payable on January 1 of each year, and requiring county secretaries to report to State secretaries all members in good standing, together with their per capita assessment for the current year not later than March 31. State societies desiring to do so may provide a shorter period. (3) Regarding the prorating of dues they recommended that this be made optional with each local society. (4) Regarding an admission fee for membership the committee recommended that this be made optional with local societies. (5) That the House of Delegates of the American Medical Association be asked to consider the advisability of issuing charters to constituent State associations. (6) As the committee recognized the value of the conference of secretaries to the State association secretaries, and to the purposes of organization, it therefore recommends that future conferences of this character be held.

**Report of the Council on Medical Education.**—Dr. Arthur Dean Bevan of Chicago presented this report, in which he declared that the progress reported in previous years was still being continued. The Ninth Annual Conference on Medical Education was held in Chicago, February 24. Probably the most effective work carried on by the Council had been through these annual conferences which had been regularly attended by delegates from medical colleges, State licensing boards, State medical societies, colleges, associations, federations of State boards, and university presidents. These conferences had constituted an open forum in which the various problems in medical education had been taken up and given thorough and frank discussion. It was undoubtedly through these conferences that unanimity of effort by the various agencies working for an improved medical education had been secured and as a result of which such decided progress had been made. In this connection a recent bulletin issued by the United States Bureau of Education, after reproducing several pages from the Council's report, in regard to medical education said: "No more marvelous chapter in the history of educational standards can be found than in a review of the work of these conferences." The report showed that after January 14 there would be at least seventy-five medical colleges which have put into effect entrance requirements of at least one year of college work, including courses in physics, chemistry, biology, and a modern language. There were thirty-two medical schools requiring two or more years' work in a college of liberal arts in addition to a four years' high school education. There were now eleven State medical licensing boards which had adopted preliminary requirements in advance of a four years' high school education. In no section of the country had the Council had more hearty cooperation than in the South, and on the part of the medical colleges, and in no section of the country had improvements in medical education been greater than in those of the Southern States. Tennessee, which formerly had twelve medical schools, now had only five and three of these, including one negro school, had undergone a remarkable development. In Alabama, Arkansas, Mississippi, Oklahoma, and South Carolina there were now single medical schools supported and controlled by the State. The same development had been going on in the medical schools in practically every Southern State. The generosity with which the people of several Southern cities had come to the support of their local medical schools had shown what might be done in the cities of other sections of the country.

In regard to the cost of teaching medicine definite reports from sixty-five colleges showed that the expense of teaching each student ranged from one and one-half to several times the amount that the student paid in fees. The average amount paid out per student by the sixty-five colleges was $410, while the average amount received in fees was $122. With the same equipment these same schools could probably accommodate two or three times the present number of students, which would greatly reduce the disproportion of expense over income from fees, and hence a further reduction of the number of medical schools would be in the interest of economy and to the betterment of medical education. Any plea for the continuance of the low grade medical school was in the interest of the boy poor in scholarship rather than the one poor in purse, as it cost the student no more at a first-class medical school than at one of low grade. Twenty-seven States now had medical schools as integral parts of the States' universities.

As had been stated in a previous report there were, in 1904, 166 medical schools in the United States, which was nearly one-half of the world's supply. Since that time the decrease in the number of schools had been quite rapid. This had been brought about partly by the disappearance of the commercial medical schools, which had gone out of existence, but more largely through the merger of several small schools in each of numerous localities, leaving in each instance one larger and stronger school. The number of medical schools would be about 110 at the end of the present college session.

Reliable information showed that in 117 medical schools existing in 1912 there were altogether 876 full-time salaried teachers, and of this number 490 had professorial rank. This was at the rate of eight full-time teachers to each school. In regard to the opportunities for the hospital interne year, 852 hospitals reported 3,006 internes in active service. Since there were only about 4,500 medical graduates each year there were still about 1,500 graduates for whom to provide interneships. There were baout 1,400 hospitals having altogether approximately 135,000 beds, which at present had no internes. There was every reason to believe that a special campaign carried on among these hospitals would result in providing an opportunity of an interneship for every medical graduate. From these figures it would seem that definite requirements by State medical boards for a hospital interneship as a prerequisite for license could be made possible within the next few years without working a special hardship on any of the parties concerned. In referring to the subject of State licensing boards, Dr. Bevan declared that the great problem in medical licensure, therefore, was: how to secure a close cooperation between the various State licensing boards by which unanimity of action, uniformity of standards, and equally thorough methods and examinations might be obtained.

Recognizing this need of cooperation there had recently been organized the Federation of State Medical Boards, resulting from the effort to merge the two confederations which had been in existence for several years. Under the new constitution this federation gave promise of doing effective work and it certainly had a great opportunity. It was hoped that all State medical boards would unite with this organization not only for the added protection it would furnish for the individual State but also for the great good that could and needed to be accomplished for the country as a whole. The work in connection with medical colleges had now reached a stage where an American standard of medical education was well fixed and the chief efforts should be not so much toward higher standards as in securing international improvements, better teachers, better hospital and dispensary facilities, more research, and, above all, greater endowments. The marked improvements made in medical colleges in recent years revealed in marked contrast the improvements needed in medical licensures. Many States needed better medical practice acts. In each State there should be a single board in control and a single educational standard by which all practitioners of the healing art should be measured regardless of the particular methods of treatment to be followed. The very best men available should be selected as members

of the licensing boards, and if possible these boards should be taken out of politics. Examinations should be made more practical and thorough whereby a student would have to show evidences of actual training rather than of cramming in quizzes or from compends.

**Report of Committee on Scientific Exhibit.**—Dr. F. Frank B. Wynn of Indianapolis presented this report. He stated that the present scientific exhibit had not been surpassed if it had been equaled at any previous meeting. The superb housing this year appealed to the scientific workers, but would probably spoil them for accepting what necessity might offer in the future. There were certain features of the exhibit that should be emphasized. Anatomy and physiology had received more attention than hitherto. Surgical pathology, both gross and microscopical, made a creditable showing. The newer methods of anesthesia and physiological researches in anesthesia were well demonstrated. A large number of exhibitors, 38 in number, had been brought to recognize the advantages of demonstrations. These were to be given at stated hours. The present aim and purpose of the exhibit was to furnish an avenue through which the fruits of research might be presented to other research workers and to the practitioner. It aimed to coordinate the work of the sections with the exhibits and several papers to be read at this meeting were illustrated in this way. The exhibit became to the real investigator a forum. It served also to democratize the profession. Snobbery did not belong in their ranks and the research worker who would withhold his work from the rank and file of the profession was a snob. The exhibit served to create an understanding between the surgeon who scoffed at the laboratory and the laboratory worker. It served as a restraining influence binding together all the agencies working together toward medical advancement. They owed a debt of gratitude to those who had contributed to this work and could do no less than give them the patronage they deserved.

**Report of Committee on Anesthesia.**—Dr. W. D. Gatch of Indianapolis presented this report in which he stated that the committee was of the opinion that the subject of anesthesia was too broad, and that its practical hearings were too important to be reviewed adequately in a brief report. They felt that the time had come when this committee should do for anesthesia what the council of pharmacy had done for pharmacy, namely, make a thorough-going, critical investigation of every phase of the subject. For the following reasons they believed that there was need for such an investigation: (1) Communications from surgeons and anesthetists in all parts of the country that there was a general dissatisfaction with the present results in anesthesia. Deaths and postanesthetic complications were far too common. (2) There had of late been a tremendous interest in everything which had to do with anesthesia. The physiology, pathology, and pharmacology thereof were being studied by many investigators and numerous new methods were being tried. The proper evaluation of these procedures required thorough investigation, for there was danger that at least in unskillful hands many of them might cause harm, and that, therefore, some very useful methods might fall into discredit. (3) Ether, nitrous oxide, and choloroform had obvious disadvantages, and it was not unreasonable to hope that scientific pharmacology might be able to discover new and better anesthetics. An investigation of the kind they advocated might do much to stimulate work with this object in view. Good results in anesthesia depended not only on the skillful administration of the anesthestics, but also on careful preliminary examination and preparation of the patient, intelligent cooperation of the surgeon and anesthetist, and proper postoperative care. To secure the necessary attention to each patient required a hospital organization especially adapted to this purpose. In each hospital some one man must be made responsible for good results in anesthesia. He must be given the authority to see that every patient was carefully examined and prepared for operation; he must confer when necessary with the surgeon concerning the anesthesia and he must be put in charge of the patient during his recovery from the same. He must have the power to instruct and direct the nurses and internes in the part of the work which they might be called on to do. Finally, he must be held responsible for every complication or accident due to anesthesia. A competent man provided with the authority outlined and cooperating with his surgeon could at the present time prevent most of the deaths and other calamities which were all too frequent under the present system. A good salary, together with the interest and importance of the work, would secure plenty of men capable of filling such a position in any city of the country.

The committee believed that every student should receive adequate instruction in anesthesia, that this should not be limited to the mere administration of anesthetics, but should be broad enough in scope to give the student an intelligent conception of all the factors that must be taken into account in planning the anesthetic for each patient. They condemned the practice of allowing students to administer the anesthetic except under very strict supervision, which should be given during the interne year.

*Tuesday, June 17—Second Day.*

The President, Dr. John A. Witherspoon, in the Chair.

**Report of the Committee on Red Cross Medical Work.**—Dr. George W. Kober of Washington reported that on April 30 fifty-seven county medical societies in twenty-four States had organized committees and a number of secretaries of county societies had acknowledged the receipt of the communication and had promised to bring it to the attention of the respective bodies at the next meeting. He would supply the names of five physicians to serve as members of county committee on Red Cross medical work, two of whom should be the president and secretary of the county medical society ex-officio. In case of a disaster requiring the intervention of the Red Cross, that organization would be in a position to call upon the county committee to select a sufficient number of qualified medical men for service to advise with the representatives of the society on questions of medical policy and procedure. The Red Cross would thus be assured of the services of qualified medical men.

**Report of the Committee on Scientific Research.**—Ludwig Hektoen of Chicago reported that the committee had during the past year given special grants of $200 to Dr. A. Sophian of New York, Dr. R. M. Pearce, Dr J. H. Austin, Dr. Arthur D. Eisenbrey and Dr. O. H. Pepper of Philadelphia for experimental work on contagious diseases.

**Report of the Committee on Nomenclature and Classification of Disease.**—Dr. Cressy L. Wilbur of Washington reported that after the last meeting it had been found that only a tentative edition of 1,000 copies was possible. He trusted that the work might proceed and that a plan might be found for general distribution to physicians of copies of a brief booklet containing the nomenclature and asked that members of the committee be continued.

**Report of the Committee on a Memorial to the Medical Officers Who Lost Their Lives in the Civil War.**—This committee reported that the formation of a general committee of one from each State had progressed rapidly since the issuance of an explanatory circular letter to one delegate in each State requesting nominations to the central committee. The complete list of naval surgeons who lost their lives during the Civil War was received from the Bureau of Medicine and Surgery of the Navy Department. Both in Illinois and Georgia memorials embodying the sentiments advocated in the first report of the committee were about to be erected. The committee asked that it be continued with all the privileges, instructions, and appropriations authorized by the House of Delegates in 1909.

**Report of the Committee to Consider the Mode of Commemorating the Completion of the Panama Canal.**—The report submitted recommended: First, the American Medical Association at its 1913 meeting should memorialize Congress to establish a permanent monument in recognition of the great work of Americans in sanitary science and preventive medicine. A hospital for tropical diseases would fullfil the purpose of such memorial. Second, the committee should be authorized to carry out the plans generally submitted last year and such authorization should be specific in indicating the organization of a congress and the constituency of such a congress. Third, provision should be made for funds sufficient to carry out the plans and the way such funds should be available should be specified.

**Report of a Committee to Advise with the British Medical Association.**—Dr. W. W. Grant reported that nothing definite had been accomplished and stated that the committee asked to be continued or a new committee should be constituted to complete its task. The House of Delegates should empower it to arrange for such a joint session, should this be desirable, it being definitely understood that in the interim between the meetings of the House of Delegates the committee should act in cooperation with and under the sanction of the Board of Trustees.

**Report of the Committee on Clinics.**—Dr. Charles

Mix of Chicago announced that Minneapolis and St. Paul had only modern amphitheatres seating not more than thirty-five or forty persons, hence they had been modest in announcing clinics. Clinics would be given on Friday and Saturday, however. This committee requested that the same publicity be given to its work as to that given to the sections. They thought it desirable that the program of their work should appear on the regular program. The great success of the clinics showed that they were in demand.

Dr. G. Wythe Cooke of the District of Columbia presented a resolution providing that each constituent society should have control over its own membership without interference from the American Medical Association. Any member of a constituent society after removing from his district remained eligible for the American Medical Association for eighteen months, after which he was no longer eligible until he had reestablished himself by becoming a member of the local society in the district in which he resided.

**Baltimore Home for Physicians' Widows and Orphans.**—Dr. Randolf Winslow of Baltimore presented a petition from the manager of a home for widows and orphans of physicians proposing to turn over the property and franchise of the home to the American Medical Association. The property was a building three and one-half stories in height, in the best residence district of Baltimore. Its scope was already national and the only object in making this offer was to provide for permanence. The only condition was that the home should continue under the present management and should remain in Baltimore.

All reports of officers, councils, and committees and other communications were referred to their appropriate committees.

---

GENERAL SESSIONS.

*Tuesday, June 17—First Day.*

The President, Dr. Abraham Jacobi, of New York, in the Chair.

**Invocation.**—The Reverend James E. Freeman, D.D., of Minneapolis, made the invocation.

**Addresses of Welcome.**—Dr. George Edgar Vincent, President of the University of Minnesota, said that the State of Minnesota maintained a center of scientific investigation and liberal professional education. To the members of the University community it was a keen satisfaction to welcome this distinguished body, dominated by scientific spirit and by educational ideals. In the days when specialization in research seemed to isolate investigators from one another it was well to remember that fundamental to all specialized tasks was a method and an aim which bound all separate inquiries into one inspiring cooperative search for truth. It was also well to remember that science was a unity. The Medical School extended fraternal greetings of genuine warmth. In this school the University took a just pride. To the upbuilding of this school the medical men of these cities had devoted themselves loyally. Under conditions sometimes disheartening they had persisted with courage and unflagging zeal. Gradually the unification of medical education for the whole State was achieved. Minnesota enjoyed the distinction of a unified medical education under State control. The close association between the laboratory and the Medical School and the State Board of Health afforded efficient concentration. The school was fortunate in the complete control of its own hospital whose capacity, by a recent act of the legislature was increased to 175 beds. Inasmuch as the hospital received only charity patients, certain complications which sometimes arose when hospitals were conducted on another basis, were happily avoided. The affiliation with the city hospitals of Minneapolis and St. Paul provided a wide range of clinical material and gave the school facilities for thorough instruction.

While the Medical School laid more stress upon men than buildings, it would be affectation to conceal the satisfaction which the institution felt in the new and completely equipped laboratories which had been provided for the medical school. These represented an immense amount of labor, study, planning, and supervision on the part of the members of the medical staff. If the Medical School of the university was not satisfied with merely being in Class A plus, but had the ambition to occupy a high place in that honored list, its friends would set this down to the natural hopefulness of this buoyant region. They hoped to win an increasing recognition for their devotion to high standards and ideals of undergraduate teaching, development, graduate instruction, and the fostering of medical research. They looked forward to the time when the Medical School would be brought into close relationship with the various hospitals and institutions of the State. Through this agency the university might increase the scope and efficiency of its service to the commonwealth.

One aspect of medical education gave considerable concern. The universities relied upon the American Medical Association to do a part in solving the problem. A number of years were required for medical education and the consequent expense created a danger of limiting the area of ability from which the medical profession was recruited. To the plea that individuals had a right to a short and easy road to professional practice one might turn a deaf ear, but here the interests of the public transcended those of individuals. Cheap medical education was most expensive for the community. But to limit the candidates for medical practice to those who were economically strong was a wholly different thing. There was reason to believe that men and women who might contribute much to the progress of medicine were now excluded from candidacy. A system of scholarships, maintained through private endowment, through State aid, or through the cooperation of an association might go far toward meeting this difficulty. The ranks of the profession must be open to the best ability, wherever it was to be found.

This community was honored by the presence of men and women dominated by the scientific spirit. In a sense with the advance of knowledge the area of disagreement was narrowed. As phenomena were investigated and laws were formulated, differences of opinion yielded to convincing tests of truth. As underlying medical sciences developed, as clinical research extended its area, sects, and schools of medicine must lose their significance and surrender to science that knew no fundamental antithesis or conflicts. There would always be a frontier on which investigators offered rival theories and where speculation throve, but research left a widening territory of ascertained indisputable truth. The members of the American Medical Association were to be felicitated also upon the socialized ideals of the medical profession. Less and less as medicine was regarded as a personal career, more and more was it exalted as a public service. This changed point of view was a part of the spirit of the times. Old individualism was gradually yielding to the new consciousness of the community, to new loyalty to the common life of the people.

The Association's conception of its social mission was admirably manifested by its interest in preventive medicine and public health. To the cynics who saw in the profession a conspiracy to keep people ill, and hence to profit by fees there seemed something sinister and incredible in the apparent desire to keep the public well. But the sincerity and social spirit of the medical profession would be vindicated as the campaign of popular education was pushed. Forgetting the older ethics which fostered an aloofness from public affairs, medical men now felt that they were more and more a part of the national life.

They who were struggling with a chaotic educational system and who needed the profession's aid, were grateful for what it was doing. In nothing has it shown a truer conception of duty than in its campaign for popular education concerning individual and public health. It realized the difference between aristocratic beaurocracy and democracy. In former times experts might in true paternal fashion command the submissive masses and expect an unquestioned obedience, but in a democracy experts must take their fellow citizens into their confidence and must tell them not only what to do but why. In the campaign for public education, the profession was not only rendering an essential service, but was also conforming to the true principle of democracy which must be built not upon unwilling submission, but upon the intelligent cooperation of the people. Finally the Association was to be congratulated upon the creation and perpetuation of the professional spirit. Man was himself only as he lived a life of cooperation and comradeship. The profession was a collective personality. Each individual made contribution to the whole but the materials and insiration for his own development were drawn from the common store. Only as men had the imagination to see their lives in wider relationships, and only as they lost their petty personal interests in larger and more generous common purposes could they attain the true possibility of personal growth. One might cherish the hope that the profession would gain steadily in loyalty to truth and in a disinterested devotion to common life, and to the high ideals of personal integrity, professional obligation, and scientific fidelity.

Hon. Wallace G. Nye, Mayor of Minneapolis, after drawing a picture of the physical attractions and financial

strength of the city, said they were not unmindful of the physical welfare and comfort and mental development of people, as the playgrounds, baths, parks, child-welfare work and the care of the sick, aged, and unfortunate, bore witness. This was a better index of the city's greatness than the extent of finances. In progressive work in the city the medical profession always took a leading part and he believed this was true throughout the country.

Hon. Adolph Olson Eberhart, Governor of Minnesota, in a jocular vein declared that it was a pleasure after the session of the legislature to look into so many honest faces. More seriously, he said that same legislature had enacted the best laws for the protection of public health that could be devised. The Medical Association of Minnesota has been active in assisting. Three hundred thousand preventable deaths annually, made them realize that help must come from the medical profession and Minnesota was ready to co-operate in the prevention of disease and in making life a little better for everyone not only in Minnesota, but throughout every country on the globe.

**Installation of the New President.**—Dr. Jacobi introduced Dr. John A. Witherspoon, the president-elect.

**President's Address.**—Dr. John A. Witherspoon of Nashville, Tenn., after referring to the multiplicity of work the Association was performing and dwelling at some length on the successful efforts of the profession during the past few years in putting the science of art and of the practice of medicine upon a higher plane, chose as his central theme the problem of establishing a national health department as a subject most suitable for the occasion. For a nation to be truly great must be strong physically and mentally. Standing as a successful republic it would not retain its proud position unless it prevented the useless loss of life. One might compute the financial loss represented by 500,000 preventable deaths annually, but as physicians were intimately associated with family life it was not financial aid that appealed chiefly to them, but unnecessary sorrow, anguish and suffering. The location of the country was such that it was exposed on all sides to the invasion of infectious diseases. Bubonic plague with its high mortality constantly threatened the country. South America and neighboring islands threatened the United States with infections peculiar to the former. All these emphasized the necessity for national protection. Uncinariasis, pellagra, and poliomyelitis threatened the country from within and there must be some organized body for combating them. Physicians had sounded notes of warning that these scourges could be prevented only by a great awakening to the dangers and by co-operation between the profession and the people. The nation should not always have a fear of an epidemic hovering over it. The progress in preventive medicine had kept well in advance and could present sanitary laws adequate for the protection of life. Such laws had made the Canal Zone, which formerly had been thought uninhabitable, a more healthful place than any of the American cities or rural districts. The Panama Canal was a monument not only to scientific engineering but also to sanitary science. Formerly the death rate in the Canal Zone among foreigners was 170 per thousand, now it was 8 per thousand. Should not the people at home have the same protection as those in Panama? It had ever been the aim of the profession to add to the health and happiness of the race, yet there were those who would stay this progress. The profession would welcome any force, any "ism," cult, or sect, that could truly help in the betterment of man's life. The forces opposed to them were destructive and not constructive. The medical profession would accept help from any source and would be glad to proclaim the source. They had been accused of being a medical trust, but they were prosecuting a work that was limiting the income of every one of them. The organization was based on the strongest possible democratic principles. The individual membership was fresh from the county societies and this membership was represented on the governing board. There was no way of making greater democracy. Eleven years ago medical education was in a chaotic state. It was now giving the public men properly trained who could prevent disease. The people must be educated to appreciate the loyalty of the profession to the interests of the public. They were made to feel a sense of gratitude for having through better medical education produced physicians with high ideals capable of teaching people how to stay well and to maintain sanitary conditions in cities and towns. The people were awakening to the demands of the hour and audiences were being addressed all over the country on health matters. They were showing enthusiasm in helping on the work for cleaner homes and cleaner cities. The Association stood for a National Department of Health. To secure success it needed cooperation from the doctor in the rural district to the professor in the university. When they appreciated this fact they would have laws for the protection of health and for sanitation. The doctor should go back and assert his right to be his brother's keeper.

---

SECTION ON PRACTICE OF MEDICINE.

*Tuesday, June 17—First Day.*

Dr. W. Jarvis Barlow of Los Angeles in the Chair.

**Chronic Arthritis.**—Dr. Leonard W. Ely of Denver said that the treatment of arthritis had usually devolved on the orthopedist, but he believed that it would eventually fall to the internist. The pathology of most cases of arthritis of chronic type essentially was the same whether it was tuberculous, syphilitic, gonorrheal, hemorrhagic, or traumatic. The commonest type was characterized by proliferative inflammation of bone or cartilage or of both, and this was the result of a change in the synovia and marrow. The changes in the synovia were observed more easily than those in the marrow. The symptomatology was the same whatever the etiology. In some cases the process did not enter the joint and the cultures from the joint were negative. The skiagraph was the same in all the varieties. The differentiation was often possible through the history or the general examination. A great group of nontraumatic arthritides were due to microorganisms. The only way to make a positive diagnosis was to detect the causative organism. The main indication in the treatment was to find the focus of infection and to treat that. Even if definite syphilis could not be demonstrated a course of antisyphilitic treatment was often of advantage. Immobilization was useless where syphilis existed. The prognosis in multiarticular forms presented unsolved problems, but the outlook was not hopeless. Every case furnished a field for patient study. Frequently infection was found in other parts of the body, as the tonsil or nasal cavities. The tonsils should be removed as a routine measure, even when nothing pointed to their infection. Those cases in which the cause was unknown seemed also to be the result of an infection.

Dr. R. C. Cabot of Boston asked if Dr. Ely had seen any cases of multiarticular arthritis cured by the removal of the focus of infection. He had yet to see one case cured in this way.

Dr. Yeager of Hayward, Wis., said rheumatic affections were not yet shown to enter the body by way of the tonsils nor has it been proven that the tonsil is a filter or that removing the tonsil removed the filter.

Dr. Joseph H. Miller of Chicago believed that Ely was correct in taking the stand that infection frequently caused arthritis. Often if the tonsil was removed an abscess was found at the base. If this infectious material was injected into the rabbit it produced arthritis. He believed these were cases helped by treating the focus of the infection.

**Remote Effects of Lesions of the Prostate and Deep Urethra.**—Dr. Thomas McCrae of Philadelphia said that the work of recent years showed the frequency of these lesions in the genitourinary tract. Their local importance was well recognized, but it was necessary to appreciate the results in view of the symptoms which might follow from influences on other organs. The urethral lesions were not infrequently responsible for a general nervous disturbance which might have secondary results. Such diseased sexual organs caused general disturbance out of proportion to the local lesion. Often there was no history to show prostatic disease. This by no means meant that in all males with nervous disturbance this condition was due to disease in this locality, but it was well to look in this direction. Pain might be referred to the kidney, the back, the abdomen, the hip, or the outer side of the thigh, when there was not the slightest sign of disease in the deep urethra or prostate. Arthritis secondary to infections in this locality was possible, especially arthritis of the spine. If one found the local infection and cured it arthritis would be cured. The physical condition of the patients had interested him. He found that after the operation the cardiac condition improved in many cases. It was a point worth raising whether the prostatic condition did not affect the myocardium. There was often a picture of angina pectoris from these local lesions which sometimes caused anxiety. The condition might act adversely on the kidney. What was needed was to get the prostate away. He discussed this subject because the prostate as a cause of nervous disease might easily be overlooked.

Dr. Hugh H. Young of Baltimore said that in the past medical men had been so interested in auscultation, etc., that the thought of a rectal examination was beneath their dignity and they delegated the duty to an incompetent assistant. The prostate, along with the tonsil and intestinal tract, deserved attention. Abroad 90 per cent. of males had prostatic trouble, but there were not so many in this country. Head of London had shown how easily an impulse was sent to the spinal cord, which referred it to other localities; in fact, to almost any portion of the anatomy below the diaphragm. The question of referred pain in pelvic diseases of women was understood, but it was neglected in the male, although it occurred more frequently in the latter.

Dr. W. Bridges of Omaha said that one disturbance often overlooked was an abdominal tumor dependent upon the prostate which obstructed the urinary outflow, causing the accumulation in the bladder and a pressure on the pelvis of the kidneys.

Dr. James M. Anders of Philadelphia said that even if there was no history of gonorrheal infection it would not do to hold the view that there was no infection. The *Bacillus coli* or other agents might cause some trouble.

Dr. Walter Biering of Des Moines, Ia., related a case of abscess of the right leg, general septicemia, and death. Autopsy revealed a deep-seated abscess of the prostate and fibrosis of the myocardium. The history showed that the patient had had gonorrhea five years previous.

**Studies on Uric Acid in the Blood and Urine with Special Reference to the Influence of Atophan.**—Dr. James S. McLester of Birmingham, Ala., said that the determinations of uric acid in the blood and urine in health disease were made by the new calorimetric method of Folin. Wide variations were seen in presumably normal individuals, but the content in a given individual was constant. Still greater variations occurred in disease, gout, nephritis, disease of the central nervous system, and especially syphilis showed the highest values. Atophan produced variable polyuria and a marked increase in urinary uric acid which increase was directly proportional to the uric acid loss in the blood.

Dr. William S. Thayer of Baltimore said that apart from the therapeutic side the method of Folin was of value from the diagnostic viewpoint, especially in gout. There was more gout in this country than was thought. Many cases were regarded as polyarthritis but later they proved to be gout. This method should be of diagnostic value.

Dr. H. A. Freud of Detroit said that the subject of uric acid diseases deserved more attention. They were recognized in Europe but not in this country. The examination of the urinary uric acid output by means of calorimetric methods was open to criticism on the grounds of inaccuracy. He believed that atophan acted directly on the kidneys. The way to determine the presence of gout was to put the patient on a purin-free diet for a few days and then determine the amount of uric acid. Then one should place the patient on thymus to determine the output. One should then give atophan to see if the amount was increased.

**Entamebic Infections in the Northwest.**—Dr. Griffin of Rochester, Minn., stated that in the examination of 1700 patients for parasites entamebæ were found in 227. Of this number *Entameba tetragena* and *Entameba histolytica* were found in 79 cases, and *Entameba coli* in 148. Patients probably infected while residing in the Middle Northwest numbered 147. *Entameba tetragena* and *Entameba histolytica* were found in 41 cases from the middle Northwest; *Entameba coli* was found in 106 cases in the Northwest. The patients complained chiefly of diarrhea. Thirteen had severe attacks with bloody stools, not as severe as in the South. Three-fourths of the patients complained of pain; four of rectal pain; several of indefinite gastric pain. The eosinophilic count was low. In suspicious cases search for parasites should not be abandoned too soon. Some of the cases gave histories of the disease extending over five, ten, or even twenty years. Coal oil enemata had been used in four cases with excellent results. They should be given a trial.

Dr. Yeager, Hayward, Wis., said that if the patient were given a dose of magnesium salts, the stools would show amebæ. In any bowel affection the eosinophilic count was of little value. He advised sixty to one hundred grains of ipecac daily for several days administered in five grain pills, coated with salol, which did not dissolve until they reached the intestine. This he thought was good treatment. Emetine hypodermically was effective.

Dr. Dixon of Nashville said that emetine was the most satisfactory treatment with which he was familiar.

Dr. George N. Head of Minneapolis said that when the physician found a case of chronic diarrhea in the North he should examine for amebæ, as he would if he were in the South.

Dr. Griffin said that they injected a quart of coal oil into the large bowel twice a week. It caused no irritation except in the rectum; this was relieved by vaseline. By coal oil he meant kerosene.

**The Value of the Tuberculin Reaction in Early Cases of Tuberculosis.**—Dr. V. C. Vaughan, Jr., of Detroit, Mich., said that tuberculin reaction was the phenomenon of sensitization at some stage in most early cases of tuberculosis. The recent conclusions were practically confirmatory of those announced in 1909. The extreme sensitiveness of a von Pirquet reaction rendered it doubtful in the diagnosis of active tuberculosis in adults. The subcutaneous method was useful only in hospital or sanatorium treatment. The dangers of the calmette reaction were overestimated in the experience of the author if properly applied. A failure of reaction indicated either an absence of tuberculosis disease or an inability of the patient to react to tuberculin. From clinical experience the secondary reactions following second instillations of tuberculin into the eye were of definite value in the ultimate diagnosis in suspected cases. When the first reaction was positive it was confirmatory of tuberculosis; when negative it was of no value in the diagnosis of tuberculosis. A positive secondary reaction following a negative primary reaction was against active tuberculosis. A secondary negative reaction following a primary negative reaction was of no value in the diagnosis of pulmonary tuberculosis.

Dr. Richard C. Cabot of Boston said the safety of the ophthalmological test was questioned. The experience of many showed it was dangerous and he advised against its use. The greatest value of the tuberculin test was in children. Nearly all adults reacted to the von Pirquet test. The subcutaneous tests were valuable when there was a local reaction in bone and joint tuberculosis. The *x*-ray was an important method in diagnosis, but he deprecated the phrase calcified tubercle, as the *x*-ray showed not pathological processes but only density. This must be interpreted.

Dr. Charles L. Minor of Asheville feared the calmette test and used the subcutaneous method. He thought it safe outside of the sanatorium.

Dr. F. M. Pottenger of Monrovia, Cal., said a diagnosis of tuberculosis in the adult was never made on the basis of the tuberculin reaction, but was of some value if properly interpreted. If the reaction came on promptly it showed the presence of ferments and that the patient was fighting infection. In the chronic fibroid type of disease the reaction appeared as late as the tenth day, but in the active cases it appeared within twenty-four hours. There was no one symptom, or tuberclin test, *x*-ray, or physical examination sign that decided the diagnosis. A good diagnostician was to be trusted better than a poor radiographer.

**Artificial Pneumothorax for the Relief of Advanced Pulmonary Tuberculosis.**—Dr. Charles L. Minor of Asheville, N. C., considered the method of puncture versus cutting. The Armor method was less alarming to patient and generally more desirable. The indications for this procedure were unilateral, severe advanced trouble of short duration; bilateral involvement, severe on one side, slight on the other, and not over one-third of lung destroyed by disease; persistent bleeding; unilateral small, but very active, advancing foci were contraindications. Pneumonic phthisis, active foci in good lung, intestinal trouble, bad adhesions, an anxious patient, emphysema, bad general condition were not contraindications. He had used this procedure in 22 cases; three failed; four did badly; two, not so badly; two did well, then badly; two were negative; two were good and two others were good so far. These were all advanced hopeless cases and three were saved, or a percentage of 13.

Dr. S. Adolphus Knopf of New York said that a year ago he was skeptical as to this procedure but now used it in selected cases and had had 25 per cent. of improvements with it. It was indicated in cases of uncontrollable hemorrhage. Five hundred c.c. of nitrogen stopped hemorrhage. Not many cases were suitable for operation, and those not under constant observation were to be avoided. A slight invasion of the other side was not a contraindication, but cases where there was much invasion should be left alone. It was a serious operation to be used with the utmost precaution. One should be prepared for accidents as air embolism. One should use oxygen first, and be sure to reach the pleural cavity.

Dr. Mary E. Lapham of Highlands, N. C., used oxygen in preference to nitrogen because it was absorbed faster

and helped the patient more. It had a tonic effect, and gave greatest relief. They followed cases with *x*-ray examinations but also by watching the line of resonance. She emphasized the necessity for examination before and after puncture.

**Rest and Repair in Pulmonary Tuberculosis.**—Dr. John W. Flinn of Prescott, Ariz., said that in both the plant and animal kingdoms rest was essential to growth. In infancy development was in its highest state of activity, and the healthy infant passed the greatest portion of its life in a state of rest and sleep. Repair was but the repetition of growth and for it rest was just as necessary as in injury to limbs when rest was obtained by splints, bandages, etc. In the case of the heart and lungs rest could be gotten only by resting the whole body in the recumbent position. Rest in bed was the most powerful curative agent in the treatment of active tuberculosis. One or two months in bed were necessary in the beginning of treatment of all cases. If the disease was very active the patient should be fed by a nurse and treated as in typhoid fever. Bed treatment should be continued until the temperature and pulse had both been normal for some little time and the weight was nearly normal. The rest treatment of tuberculosis had been attended with brilliant results.

**Studies in Blood Pressures in Tuberculosis at High Altitudes.**—Drs. Leroy S. Peters and E. S. Bullock of Silver City, N. M., said that heretofore the knowledge of climate in tuberculosis had been based solely on experience. However, in the past few years much work had been done to place the question of climate in the treatment of this disase on a scientific basis. They had shown conclusively by a study of six hundred cases of consumptives treated at the elevation of 6,000 feet at Silver City, N. M., that the blood pressure of consumptives was materially raised so that it approached the blood pressure of normal individuals at the sea level. They contended that any factor which served to restore the body conditions to a normal tended to better the condition of the disease. These findings might explain to some extent the reason why results in the treatment of tuberculosis at high altitudes were better than those at sea level.

---

SECTION ON DISEASES OF CHILDREN.

*Tuesday, June 17—First Day.*

Dr. Henry Dwight Chapin of New York in the Chair.

**Chairman's Address: Radiographic Studies of the Intestines in Infants.**—Dr. Henry Dwight Chapin of New York called attention to the benefits to be derived from a study of anatomical conditions by use of the radiograph because of the differences which recent use of the apparatus had brought to light between living and dead subjects. He described fully the technique with which he had been most successful, the length of time it took for the bismuth to go through the digestive organs, and from his experience deduced that there was much difference in mobility of the colon and that the sigmoid was shown to occupy a great deal more space than had commonly been supposed.

**The Use of the Röntgen Ray in the Diagnosis of Obscure Abdominal Conditions in Infancy and Childhood.**—John Lovett Morse of Boston read this paper and by the use of the stereopticon pointed out the use of the *x*-ray in differential diagnosis. In many cases it would be possible to differentiate between pyloric stenosis, pyloric spasm, chronic gastric indigestion, and splanchnoptosis in a few hours with the Röntgen ray and determine which were surgical and which amenable to medicinal treatment. It also showed marked usefulness in determining cases of intussusception and infectious diarrhea which under ordinary methods were frequently confused, in revealing the causative factor of recurrent vomiting which was often puzzling, and also in determining the presence of abdominal tumor.

**The Use of the Röntgen Ray in Pyloric Obstruction.**—Dr. L. R. DeBuys of New Orleans, after a brief reference to the use of the *x*-ray in the study of the adult stomach, said that the findings were of little aid in the infant. The use of the Röntgen ray had shown the false ideas previously held as to the size, shape, and position of the infant's stomach and had corroborated the theory that high fats retarded the movements of the stomach. It had also shown clearly the phenomena that had made differential diagnosis difficult. To be of the most value the observations should be made under as nearly normal conditions of feeding, etc., as possible. He had been surprised to find that by the time the last food went into the stomach the first had already left it in the process of digestion. He showed with motion pictures peristaltic waves.

Dr. A. Jacobi of New York said that from the plates shown he concluded that some of the cases were what used to be termed congenital constipation, a condition in which the sigmoid was so long that it formed two or three saccculations with a resulting chronic constipation. When a baby had been constipated from birth, and fed only breast milk, it was reasonable to suppose that the sigmoid was so long that it bent upon itself with resulting constipation and sometimes actual obstruction.

Dr. G. R. Pisek of New York said that any serial, instantaneous pictures that could be taken without danger to the infant were of the utmost value in diagnosis. Even in the diagnosis of stenosis alone, to get the patient into the hands of the surgeon quickly or to save some cases from unnecessary operation, would repay a great deal of study. He thought it possible that the Röntgen ray would determine in early life many conditions to be the precursors of anatomical diseases of adults.

Dr. Cole of New York wished to know if Dr. Chapin considered the contractions which showed in the pictures of two of his cases after the giving of enemas something that would occur with ordinary feedings or that was due to a spasm from the unusual filling of colon.

Dr. Crane of Kalamazoo, Michigan, thought that taking plates would fail to impress general practitioners because the fluorescent screen presented a true moving picture of the stomach and intestines and was a truly clinical method of examination, because the bismuth could be seen as it entered the stomach and the contractions of the stomach and the quantities in which the bismuth was mixed could be watched. He thought it necessary to take twenty or thirty plates to make any careful study with the Röntgen ray while with the screen this number would not be necessary, also a waste amount of work need not necessarily be done to enable a physician to interpret the pictures thrown upon the screen.

Dr. H. F. Helmholtz of Chicago wished to know if it was possible to make a diagnosis of abnormality from pictures alone.

Dr. H. Lowenberg of Philadelphia thought the same diagnostic results could be obtained by the use of charcoal. He thought that if the child passed any feces at all and retained its weight or gained a little it should be withheld from operation and studied.

Dr. Morse, in closing, answered Dr. Helmholtz's question in the negative and said that it was necessary to have the symptoms in addition to the picture to make a diagnosis.

Dr. DeBuys, in closing, said that many substances would give equally good shadows, but he used bismuth because it had no ill effects and was perfectly safe. He thought that it was common to procrastinate so long in these cases that they became poor surgical risks and urged the use of any measure that would reduce the present high mortality of 50 per cent.

Dr. Chapin, in closing, said that as Dr. Cole suggested the contractions might have been due to spasm, but he thought that more probably these were to be attributed to the peristaltic action of the colon.

(*To be continued.*)

---

# State Medical Licensing Boards.

## STATE BOARD EXAMINATION QUESTIONS.

Medical Examining Board of Virginia.

*June, 1912.*

(*Continued from page 1058.*)

MATERIA MEDICA.

1. State difference between a tonic and a stimulant, giving an example of each.
2. What are the preparations and doses of arsenic?
3. What is alcohol and what its medicinal uses?
4. Give doses of following: Creosote, sulphate of spartein, phenacetine, caffeine citrate, atropine, potassium iodide.
5. Give the classification of gentian, chloroform, magnesium sulphate, strophanthus, santonine, viburnum prunifolium.
6. What are the principal medicinal uses of digitalis?
7. What are (1) antiseptics, (2) germicides, (3) deodorants? Giving an example of each.

TOXICOLOGY.

1. Give symptoms, minimum fatal dose, and treatment of poisoning by arsenic.

2. When lucifer match heads are taken into stomach what is best treatment and what should be especially avoided?

3. Give chemical and physiological antidotes for opium, strychnine, and carbolic acid.

THERAPEUTICS.

1. Classify emetics and give two examples in each class.

2. Give therapeutic uses of digitalis and the objections to its long continued use.

3. Give uses of iodine and name preparations most prescribed internally.

4. Name the urinary acidifiers and state whether the bicarbonates should be given before or after meals for such effect.

5. Give the leading action of each of the three principal mineral acids

PATHOLOGY AND BACTERIOLOGY.

1. What is meant by the term "compensation" as used in heart diseases? Trace the course of events due to broken compensation.

2. Give the etiology and pathology of erysipelas. Through what channels does it spread?

3. Discuss syncope, shock, and collapse, and state what features are common to all three conditions.

4. Distinguish between hemoptysis and hematemesis. Name the diseases of the organs that may produce the latter.

5. Describe the phenomenon known as Cheyne-Stokes respiration. State some of the conditions in which these respirations appear, and give the prognosis of same.

6. Give the pathology of nephrolithiasis.

7. The power to induce (by biological reaction) the formation of what distinguishes toxins from other poisons—such as alkaloids?

Of what disease is the *Spirocheta pallida* the exciting agent?

8. How do bacteria multiply? Mention three pathogenic bacteria that may be conveyed from the soil. Describe the *Bacillus tetani*.

9. How does an antitoxin differ from a vaccine?

10. How would you prepare and stain a specimen of sputum to examine for the baccilli of tuberculosis?

PRACTICE OF MEDICINE.

1. Differentiate from one another—apoplexy, epilepsy, alcoholic intoxication, and uremia.

2. Give the etiology and clinical symptoms of catarrhal (broncho or lobular) pneumonia.

3. Differentiate cardiac hypertrophy from cardiac dilatation.

4. Define: urticaria; herpes zoster; astigmatism; amnesia; aphasia.

5. Give the clinical symptoms and treatment of acute nephritis.

6. Describe a typical case of measles from the time of infection to its close.

7. Give the clinical symptoms of eczema and its treatment, including diet.

8. Give the principal measures for protection against malarial, typhoid, and yellow fever.

9. Give the treatment for follicular tonsillitis.

10. What factors determine normal blood-pressure and what is the normal pressure for an adult?

## ANSWERS.

MATERIA MEDICA.

1. The terms stimulant and tonic are both used laxly. In Foster's *Dictionary of Practical Therapeutics* stimulants are defined as "agents whose influence is to augment the vital activity or function of an organ or to increase the vital energy of the entire system." *Tonics* are said to be "measures which are employed for the purpose of restoring permanent energy or tone to weakened, impaired, or diseased organs or systems of organs or the organism at large." Alcohol is an example of a stimulant; strychnine, of a tonic.

2. Arsenic trioxide, gr. 1/20; solution of arsenous acid, ♏viij; solution of potassium arsenite, ♏viij; sodium arsenate, gr. 1/10; exsiccated sodium arsenate, gr. 1/20; solution of sodium arsenate, ♏iij; arsenic iodide, gr. 1/10; solution of arsenic and mercuric iodide, ♏jss.

3. Alcohol is a liquid containing about 93 per cent. of ethyl alcohol and about 7 per cent. of water. It is used medicinally as an antiseptic, astringent, and refrigerant; for bruises and sprains; in headaches, in fevers; to check sweating; in diphtheria, pneumonia, snake-bite; as a stimulant, a food, and as a diuretic.

4. Dose of creosote, ♏iij; sulphate of sparteine, gr. 1/5; phenacetine, gr. vijss; citrated caffeine, gr. ij; atropine, gr. 1/160; potassium iodide, gr. vijss.

5. Gentian is a stomachic; chloroform, an anesthetic; magnesium sulphate a cathartic; strophanthus, a circulatory stimulant; santonin, an anthelmintic; viburnum prunifolium, an antispasmodic.

6. *Therapy of digitalis:* Digitalis is indicated in diseases of the heart, (1) when the heart action is rapid and feeble, with low arterial tension; (2) in mitral lesions when compensation has begun to fail; (3) in nonvalvular cardiac affections; (4) in irritable heart, due to nerve exhaustion. Digitalis is also a diuretic; and it is also used in some forms of nephritis, exopthalmic goitre, pneumonia, chronic bronchitis, etc.

7. An *antiseptic* is a substance which prevents or restrains putrefaction; example, cold. A *germicide* is a substance or agent which destroys bacteria and their germs; example, mercuric chloride. A *deodorant* is a substance or agent which destroys foul odors; example, sulphur dioxide.

TOXICOLOGY.

1. *Symptoms of arsenic poisoning:* Nausea, faintness pain in stomach, vomiting, purging, and pain in extremities; the vomitus is blood-streaked. *Minimum fatal dose* is probably between two and four grains. *Treatment* consists in the administration of freshly prepared solution of ferric hydroxide.

2. Give an emetic (copper sulphate or apomorphine), or wash out the stomach with a 0.2 per cent. solution of potassium permanganate, and then with warm water. Old French oil of turpentine is said to be the physiological antidote. Fats and oils are not to be administered. (Note that Old French oil of turpentine is not an oil chemically.)

3. *Opium.* Potassium permanganate is a chemical antidote; caffeine, strong coffee, strychnine, nitroglycerin, and cocaine are said to be physiological antidotes.

*Strychnine.* Tannin is the chemical antidote; chloral and chloroform are physiological antidotes.

*Carbolic acid.* Alcohol and sodium sulphate are said to be antidotes.

THERAPEUTICS.

1. *Emetics* are: (1) *local* (which act directly on the nerve filament in the stomach or pharynx), such as alum and copper sulphate; and (2) *general* or *systemic* (which act through the circulation), such as apomorphine and ipecac.

2. See above, MATERIA MEDICA, 6. The objection to the long continued use of digitalis is its cumulative action; the heart may be so strained by overstimulation that some slight but sudden exertion may cause cardiac failure.

3. *Iodine* is an irritant, vesicant; it is used as a counter irritant in glandular tumors, cysts, hydrocele, skin diseases, fissures. It is an antiseptic and disinfectant. Iodine is but little used internally. The preparations are: Tincture of iodine, ♏iss; compound solution of iodine, ♏iij, well diluted; and ointment of iodine.

4. The *urinary acidifiers* are: Acid sodium phosphate, benzoic acid, salicylic acid, vegetable acids, salol, and potassium bitartrate. The bicarbonates are not urinary acidifiers.

5. Hydrochloric, sulphuric, and nitric acids are all escharotic. Further, *hydrochloric* acid is a bleaching, deodorizing, and disinfecting agent. *Nitric* acid is a good local escharotic because its action is limited to the spot where it is applied. *Sulphuric* acid, on the other hand, has an escharotic action which spreads; this is owing to the strong tendency of this acid to unite with water.

PATHOLOGY AND BACTERIOLOGY.

1. *Compensation.* "The alterations in the systemic blood supply caused by the valvular defects of chronic endocardial inflammation are such that, if continued, the integrity of the body is threatened. To overcome the impaired functions of the valves and to maintain the general circulation, the heart increases in size and strength (*compensatory hypertrophy*). The period in which this occurs is called the *period of compensation;* its duration is indefinite. It may be recognized by the physical signs of valvular disease without any symptoms of disturbed circulation. Anything which disturbs the equilibrium as it now exists, such as acute diseases and excessive work, leads to ruptured compensation, a condition attended by cyanosis, dyspnea, edema, gastric, hepatic, and renal dis-

turbances, and often death." (Hughes' *Practice of Medicine.*)

2. *Erysipelas* is caused by the streptococcus erysipelatis, which enters through a wound or abrasion. The skin and subcutaneous connective tissue are inflamed, and the lymphatic vessels are also involved; there is little or no pus formation, but leucocytosis is present, and the streptococci are found in and around the lymphatic channels. Round cell infiltration is common. The disease spreads by the lymphatics, and possibly also by direct continuity.

3. *Syncope* is a state of suspended animation due to sudden failure of the action of the heart. *Shock* is a condition of general depression of vital activity due to a violent stimulation of the peripheral nerves or nerve endings of the sensory or sympathetic system; it may also be produced by a sudden or severe emotion. "*Collapse* is a condition of extreme depression of the nervous system, especially of the cardiac and respiratory centers. It is usually due to powerful afferent stimuli, but may be produced by slighter impulses, if preceded by conditions tending to exhaustion. Its chief manifestations are those of mental and physical prostration. The terms *collapse* and *shock* are often used indiscriminately in reference to conditions of sudden prostration due to injury of any kind. They are not, however, synonymous terms. *Shock* is essentially a reflex vasomotor paralysis with cardiac inhibition, the effect being produced through the vagi, depressor, and other nerves. The venous system thus becomes intensely congested, the condition being virtually equivalent to the occurrence of an internal hemorrhage. The output of blood from the heart is diminished, and the resulting diminution of arterial pressure causes acute arterial anemia, in which the brain, muscles, skin, etc., partake. Combined with this anemia is inhibition (*i.e.* slowing) of the heart's action, and lessened frequency of the pulse. But the flow of blood from the veins into the heart being deficient the pulse, instead of being infrequent and full, becomes infrequent and weak. Thus the heart has less work to perform as measured by output, and its pause or recuperative period is longer; hence it does not become exhausted. In *collapse*, failure of the heart and respiration of central origin is the essential feature, as shown by the frequent weak pulse and shallow breathing. Shock may precede, merge into, and terminate in collapse, or the latter may result directly from the cause of the shock if it is prolonged; but the shock is neither a necessary antecedent nor an invariable accompaniment of collapse." (From Quaim's *Dictionary of Medicine.*)

Pallor and a weak or imperceptible pulse are found in all three conditions.

4.

| HEMATEMESIS. | HEMOPTYSIS. |
|---|---|
| 1. Previous history of gastric, hepatic, or splenic disease. | 1. Previous history of pulmonary troubles. |
| 2. Blood is vomited. | 2. Blood is coughed up. |
| 3. Blood is dark colored and not frothy. | 3. Blood is frothy and bright red. |
| 4. Blood may be mixed with food. | 4. Blood may be mixed with sputa. |
| 5. Giddiness or faintness usually precede vomiting. | 5. Sensation of tickling in the throat usually precedes. |
| 6. Nausea and weight in epigastrium. | 6. Dyspnea and pains in the chest. |
| 7. Often followed by melena (black tarry stools). | 7. Is not usually succeeded by melena. |

"*Hematemesis may be due* to ulcer, cancer, cirrhosis, or congestion of the liver, scurvy, purpura, hemophilia, malaria, congestion of the spleen, chronic heart disease, vicarious menstruation, traumatism, yellow fever, toxic gastritis, or rupture of an aneurysm into the stomach." (Hughes' *Practice of Medicine.*)

5. In *Cheyne-Stokes respiration* the respirations gradually become deeper and more rapid, then they become shallower and slower, and after a pause of several seconds this cycle is repeated. It is found in apoplexy, uremia, chronic nephritis, tuberculous meningitis, fatty degeneration of the heart. The prognosis is grave.

6. *Nephrolithiasis.* "In the absence of septic infection, the changes in the kidney are the result of mechanical irritation, with or without retention of urine according to the situation of the stone. The irritation induces an increase in the interstitial connective tissue, whereby the organ becomes tougher and harder, and the fatty and fibrous capsules become thickened and fused with one another, and firmly adherent to the parenchyma. The mucous membrane of the pelvis is injected and swollen, and the stone tends to become buried in it. If the stone hinders the outflow from the pelvis, hydronephrotic changes result. In some cases there is a remarkable overgrowth of fat, which originates at the hilum, surrounds the calyces, and finally replaces the parenchyma, the kidney being ultimately transformed into a solid lipoma enclosing a cavity—the pelvis—in which the stone is lodged. When infective processes are superadded, pyelonephritis and pyonephrosis ensue. The perinephric cellular tissue also may become the seat of suppuration and of abscess. The addition of sepsis may result in the deposition of phosphates upon the existing stone, which may thereby be greatly increased in size. The opposite kidney may remain healthy, and may even undergo hypertrophy to compensate for the loss of function in the diseased organ, but it also is liable to become the seat of stone formation and of infection and suppuration." (Thomson and Miles' *Surgery.*)

7. *Toxins* are capable of producing antibodies or antitoxins; other poisons, such as alkaloids, cannot do this.

8. The *Spirochæta pallida* is the exciting agent of syphilis. Bacteria multiply by cell-division. A bacterium about to divide seems to be larger than normal, and if it is a coccus it becomes more ovoid; changes occur first in the nucleus, and the bacterium just falls in two. Cocci may divide in one, two, or three directions of space; bacilli divide transversely to their long axis, and spirilla divide transversely to their long diameter. *Three pathogenic bacteria that may be conveyed from the soil:* Bacillus tetani, bacillus edematis, and bacillus aërogenes capsulatus.

*The bacillus of tetanus* is characterized by its peculiar spore, formed at one end of the bacillus and giving it the appearance of a pin; it is purely anaërobic, and cannot be developed at all in the presence of oxygen. It generally comes from the soil and is found in penetrating wounds. It appears in two forms, the spore-bearing form, as described above, and the vegetative form, which is a short bacillus with rounded ends, and which may occur singly or in pairs, or may form long filaments. It grows in gelatin stab cultures in the middle of the medium and the colonies look something like a fir tree; its growth is slow, and a disagreeable odor is at the same time emitted. In bouillon, it grows near the bottom of the tube, and produces gases.

9. *Differences between an antitoxin and a bacterial vaccine:* "The antitoxic sera act directly upon the poison secreted by the living bacterial cell and neutralize its toxic property, while the bacteriolytic sera affect the bacteria themselves and destroy them or paralyze their action. Since the antibacterial sera are without effect upon the formed toxin, they are mainly useful in practice as a means of protecting against the bacterial invasion, while the antitoxic sera (*e.g.* diphtheria) may be employed to combat an infection already in progress. Broadly speaking, the latter are curative, the former protective." (Jordan's *Bacteriology.*)

10. To demonstrate the existence of *tubercle bacilli* in the sputum: The sputum must be recent, free from particles of food or other foreign matter; select a cheesy-looking nodule and smear it on a slide, making the smear as thin as possible. Then cover it with some carbol-fuchsin and let it steam over a small flame for about two minutes, care being taken that it does not boil. Wash it thoroughly in water and then decolorize by immersing it in a solution of any dilute mineral acid for about a minute. Then make a contrast stain with solution of Loeffler's methylene blue for about a minute; wash it again and examine with oil immersion lens. The tubercle bacilli will appear as thin red rods, while all other bacteria will appear blue.

PRACTICE OF MEDICINE.

1. In *alcoholic coma* the coma is not usually absolute; there may be an odor of alcohol on the breath, the patient can generally be aroused by shouting in his ear; there is no paralysis; the pupils are normal or dilated; respiration is practically normal; the pulse is first rapid and later feeble, and the skin cool.

In *uremic coma* the coma is deep; there may be a urinous odor to the breath; the urine is scanty and contains albumin; there is slow pulse, with high arterial tension; the pupils are usually small and equal; respiration is deep and may be quickened; the body temperature may be above normal, or subnormal.

In *cerebral apoplexy* there is generally paralysis of the head and upper limbs, and in left-sided lesions there may be aphasia; the pulse is slow and full; the respirations are

at first slow, regular, and stertorous, later on becoming of the Cheyne-Stokes type.

In *coma of epilepsy:* History of attack, with previous convulsion; the coma is of brief duration, and the unconsciousness gradually becomes less; there may be a bitten tongue or other scars.

2. *Catarrhal pneumonia* is generally secondary to some other disease such as diphtheria, whooping cough, or measles; but it may be primary. It is most frequent in childhood and old age; in the latter condition it is often secondary to some exhausting disease. It generally begins as a bronchial catarrh, the temperature becomes high, dyspnea and cough are present, the sputum may be bloody but it is never rusty, and is quite different from that of lobar pneumonia. Vocal resonance and fremitus may be increased, and subcrepitant râles may be present.

3. CARDIAC HYPERTROPHY: "Inspection reveals fullness or prominence of the precordium with a distinct impulse. *Palpation* detects the impulse one or two intercostal spaces lower down and to the left. It is stronger and more or less diffused—the heaving impulse. *Percussion* determines an increase in the area of cardiac dullness vertically and transversely on the left side of the sternum, unless the right ventricle is also hypertrophied, when the cardiac dullness is increased to the right of the sternum. *Auscultation* in simple hypertrophy without any valvular changes detects a loud first sound of a somewhat metallic quality, the second sound being strongly accentuated. In the presence of valvular disease the characteristic murmurs are heard in addition." (Hughes' *Practice of Medicine.*)

CARDIAC DILATATION: "*Inspection* detects enlargement and distention of the superficial veins and an indistinct, often wavy and diffused, cardiac impulse. If tricuspid regurgitation is present jugular pulsation will be observed. *Palpation* confirms inspection; the impulse is feeble, irregular, and heaving. *Percussion* serves to determine extension of the area of cardiac dullness transversely and especially toward the right side. *Auscultation* in the presence of valvular lesions reveals characteristic murmurs. If there are no valvular lesions the cardiac sounds are weaker than normal and the first sound is sharper in quality than usual." (Hughes' *Practice of Medicine.*)

4. *Urticaria* is an inflammatory condition of the skin with development of wheals, and accompanied by itching and often associated with fever and gastric disturbances.

*Herpes zoster* is an inflammatory disease with formation of vesicles along the line of a cutaneous nerve, and accompanied by neuralgic pains.

*Astigmatism* is a condition of the eye in which rays of a light from a point do not converge on the retina.

*Amnesia* is loss of memory, especially of the ideas presented by words.

*Aphasia* is inability to express ideas in speech or writing.

5. ACUTE NEPHRITIS. *Symptoms:* The first evidence of the affection is the edematous condition of the face. This edema may extend and produce general anasarca. The urine is scanty, smoky in color, and of a high specific gravity. It usually contains albumin, blood-cells, blood casts, epithelial casts, hyaline casts, and free renal epithelium. Retention of urine, uremia, intense itching of the skin, dyspnea, delusional insanity, and palsies occur.

*The treatment* consists largely in rest in bed, warmth, milk diet, and attempts at elimination of waste products. Free purgation should be secured by means of the salines, calomel, or compound jalap powder. Diaphoresis may be favored by the administration of sweet spirits of niter, and in severe cases pilocarpin, and by the use of warm baths, warm applications, or the vapor bath. Tincture of digitalis (♏ 5-20 every 4 hours), tincture of strophanthus, or spartein (gr. ¼-½) may be given as diuretics. The occurrence of uremia will require prompt and energetic measures. (*Pocket Cyclopedia.*)

6. MEASLES. The incubation period is from nine to fourteen days and the disease is attended by a more or less extensive catarrhal inflammation of the various mucous surfaces of the body. The prodromes are coryza, lacrimation, photophobia, hard bronchial or croupy cough somnolence, irritability of temper, and sometimes convulsions. The temperature rises to 100° or 104° F., and increases until the rash is fully developed. On the second day, hard papules of a dark purplish color may be seen on the palate, and on the fourth day an eruption made up of crescentic patches of small papules upon a slightly reddened base appears on the neck, forehead, trunk, and extremities. The rash remains for from one to six days, after which the symptoms subside and a branny desquamation occurs. Extension of the catarrhal inflammation may result in complications such as bronchopneumonia, laryngitis, otitis media, enteritis, tuberculosis, etc. In healthy children and in uncomplicated cases recovery is the rule. The treatment consists in rest in bed in a darkened, well ventilated room, liquid diet, isolation, and the administration of water or acidulated drinks. In the early stages an enema or mild laxative is very beneficial. (*Pocket Cyclopedia.*)

7. *Eczema.* The skin is red, swollen, hot; a discharge is present, which leads to crust formation; itching or burning is always present. The disease is often intractable. The general health must be attended to; tea, coffee, alcohol, pastry, sugar, fried meat, starches, should be reduced to a minimum or prohibited. Cathartics and diuretics are indicated, as are proper hygienic surroundings and suitable exercise. Soap should not be used over the affected part, but water containing boric acid may be employed. The crust and scales must be removed with some oily preparation, and a dusting powder of bismuth subnitrate, boric acid, or zinc oxide used. Lassar's paste has also been recommended. Tar preparations or phenol may relieve the itching, but care must be taken to use only such strengths as will not increase the irritation.

8. *Malaria* is spread by the anopheles mosquito; *yellow fever,* by the stegomyia. These mosquitoes should be kept out of the dwellings, and away from the houses. Mosquito netting should be used, swamps and weeds removed, and a general destruction of mosquitoes instituted. For *typhoid,* see HYGIENE AND PREVENTIVE MEDICINE, 5.

9. *Follicular tonsillitis* requires cold compresses to the neck; and potassium chlorate and iron should be administered internally.

10. The *factors which influence normal blood-pressure* are: Age, posture, altitude, exercise, excitement and emotion, food, alcohol, tobacco, diseases, and quantity of the blood. The *normal pressure for an adult* is about 120 to 130 millimeters of mercury; a more liberal limit places it at from 100 to 145 for young, healthy adults.

(*To be concluded.*)

## BULLETIN OF APPROACHING EXAMINATIONS

| STATE | NAME AND ADDRESS OF SECRETARY | PLACE AND DATE OF NEXT EXAMINATION† |
|---|---|---|
| Alabama* | W. H. Sanders, Montgomery | Montgomery July 8 |
| Arizona* | J. W. Thomas, Phoenix | Phoenix |
| Arkansas | F. T. Murphy, Brinkley | Little Rock |
| California* | C. B. Pinkham, 929 Butler Building, San Francisco | San Francisco Aug. 5 |
| Colorado | David A. Strickler, Empire Building, Denver | Denver July 1 |

### SCIATICA AND ITS TREATMENT.*

By EDWARD LIVINGSTON HUNT, M.D.

NEW YORK.

INSTRUCTOR IN NERVOUS DISEASES, COLLEGE OF PHYSICIANS AND SURGEONS, COLUMBIA UNIVERSITY.

To understand sciatica it is necessary to bear in mind the real meaning of the word. Sciatica is a term. A term which is loosely applied to those conditions in which the leading symptom is pain in the neighborhood of the sciatic nerve; that is to say, that the pain in the smaller sciatic nerve, in the lumbosacral plexus, in the spinal roots, from which the greater nerve springs, as well as pain along the course of the sciatic nerve itself, may be, and is, designated as sciatica. The key to the understanding of the condition is the understanding of the cause.

The causes of sciatica may be grouped under four headings: (1) Intrapelvic disease. (2) Constitutional states. (3) Damage to the nerve trunk. (4) Damage to the sacroiliac joint. Thus sciatica may be the result of specific exudates within the pelvis, of venous congestion, of pressure from a pregnant uterus, a new growth, or a loaded rectum; it may be the result of constitutional toxemias, such as syphilis, gout, rheumatism, diabetes, typhoid, sepsis, gonorrhea, chronic intestinal autointoxications, lead, arsenic, and alcohol; it may be the result of injuries, fractures, inflammations, or exposure along the course of the nerve trunk; and finally it may be the result of sprain, relaxation, or damage to the sacroiliac joint.

We owe much to Goldthwaite, of Boston, who two years ago, pointed out disease of the sacroiliac joint as furnishing the lesion in many hitherto incurable sciaticas. The lumbosacral cord, as well as the first sacral nerve, are in front of the joint, while the second and third sacral nerves are separated from it only by the pyriformis muscle. An injury, or an inflammatory condition of the joint will at once stretch these nerves, transmit the pain and cause the phenomenon known as sciatica. Do not fail then in every instance to palpate and examine this joint.

I have collated one or two practical rules which may help to distinguish a pathological joint condition:

(1) Stooping forward causes pain in the joint, together with reflex spasm of the adductors.

(2) Lasègue's sign gives pain in the joint as well as along the course of the nerve.

(3) Tenderness and limited movement of the joint.

There are some curious facts in regard to sciatica —facts which have often been lost sight of, but which, nevertheless, are instructive and interesting. I am going to mention some of these. One is that the disease occurs in men rather than women in the proportion of five to one. This may be due to the fact that the pelvis is wider, that more space is given the nerve at its exit, or to the fact that men are more liable to exposure; finally, that in women the nerve is more thickly covered.

The age at which the condition occurs is that of midlife. It is rare in old age, and, strange as it may seem, I have failed to find the report of a single case in childhood. Two or three instances are recorded of the occurrence at about the age of twelve.

Autopsies in cases of sciatica have been very rare. Although the disease is ancient and honorable, only twelve autopsies have been described. Some of these have revealed nothing, some only an enlarged, edematous, and congested nerve, some the presence of a jelly-like substance in the sheath, and some the signs of an interstitial neuritis. Microscopic negative.

Occupation is a factor in the production of sciatica. Sabareau has pointed out that it occurs most frequently in masons, gardeners, longshoremen, coachmen, and clerks. The conclusion to be drawn from this is that, so far as occupation is concerned, three factors enter into the cause. These are exposure, overexertion, and pressure from prolonged sitting on hard seats.

Climate also plays a part. Romberg observed that there were fewer cases in Berlin than in Paris. There is no doubt of the fact that the condition is more common in low altitudes and along water courses than in the hills and mountains. It is also more common at certain seasons of the year. The months of late winter, January, February, and March, a time when melting snow and dampness prevail, is the season most productive of sciatica.

An important factor is the constitution of the patient. Not only are the gouty susceptible, but also those who suffer from endarteritis, rheumatism, migraine, lithiasis, and all those diseases in which there is a new growth of connective tissue. The diabetic especially is apt to develop pain along the sciatic nerve; the characteristic feature of this type is that it is bilateral. So usual is it for sciatica to occur in the course of diabetes that in every case where the condition is apparent, there should be made repeated and careful analyses of the urine. In the gouty Charcot called attention to the fact that in the same patient outbreaks of gout and sciatica frequently alternated. Gowers reminds us that it is very liable to develop on a gouty basis.

Among the symptoms should be included polyuria. It is especially common in the grave cases, whereas in the milder, the reverse is apt to occur. A doubtful case should have an analysis for sugar

*Read by invitation before the Bronx Medical Association, April 2, 1913.

and indican, and a record kept of the quantity passed.

The symptoms of sciatica are: Pain, gait, wasting of the muscles, tenderness of the nerve to pressure, sometimes loss of the kneejerk.

*The pain* is boring in character, worse on exertion, worse in spots; the patient describes a condition in which the leg feels as though about to break. The pain can always be produced by flexing the thigh and extending the knee (Lasègue's sign). *The gait* is that of a modified hemiplegia; the leg is flexed, the knee inverted, the heel raised from the ground. There is a *wasting* of the adductor muscles. There is no R. D.

The nerve is tender to pressure in certain definite spots—at the sciatic notch, about the middle of the thigh, in the popliteal space, and back of the head of the fibula. The important point to decide in sciatica is whether the case is one of simple sciatica or of organic sciatica—that is to say, whether it is a simple neuritis or whether it is a pain the result of some other condition.

There are two or three little points which may help you to differentiate between a simple primary and a secondary organic sciatica.

In the simple sciatica the pain is apt to be more spontaneous and the nerve much more tender to pressure. In the secondary type there often occurs a sensory disturbance along the foot, together with an absence of the Achilles jerk. In this form there is degenerative atrophy, with electrical changes and much weakened muscles.

The course of sciatica is a long one. It is tedious and discouraging. A classical and typical case of sciatica will not only exhaust the patient, but usually two or three doctors. It is rare to find that the physician who started with the case, and who has done the hard work and borne the brunt of the fight, should be in attendance when the patient recovers.

The treatment of sciatica is a formidable subject. Osler once summarized it in two words, "Six months." A certain Frenchman said that there was "no treatment, but that there was a certain therapeutic method applicable to the sufferer from that disease."

The treatment must depend upon the cause. This means care and great detail. It means a thorough physical and laboratory examination. It may necessitate an examination of the blood, sputum, and cerebrospinal fluid; it may mean the taking of a Wassermann, a von Pirquet, or a luetin test. It may mean a vaginal, or a rectal examination, it may necessitate the calling in of an orthopedist. Every effort from the point of view of the pathologist, and every aid from the point of view of the clinician should be brought to bear on this point.

If the conclusion is reached that the basis of the sciatica is rheumatic, the treatment should be directed along rheumatic lines by the employment of the salicylates, aspirin, oil of wintergreen, menthol, and a proper diet; if the basis is gouty, then the treatment should be colchicum, atophan, iodide, lithia, fluids, and a restricted diet; if the basis is specific then the treatment should follow the approved course of that condition—mercury and iodides. An interesting question which would here present itself would be the advisability of giving either salvarsan or neosalvarsan. As a general principle it seems to me that if the case were clearly syphilitic, and either of recent or long standing, small and repeated doses of neosalvarsan could do no possible harm, might aid locally, and certainly would improve the general condition. If given, the other specific drugs—mercury and iodide—should not be relegated to the background.

If the conclusion is reached that the condition is secondary to diabetes, then the treatment should be that of diabetes—diet, with the removal of the sugars and starches.

If the basis of the condition is due to new growths, to pressure, or to some conditions which by mechanical measures causes the sciatica, the treatment should then be, so far as can be indicated, surgical. The general condition of the patient, together with the local indications for operation, must be borne in mind, carefully weighed, and a just conclusion reached. It is only after all of these measures have been resorted to that we are justified in calling the sciatica idiopathic.

If we find no discoverable cause that the sciatica is a primary neuritis or perineuritis, we must then resort to such methods and aids as are especially indicated in such conditions.

The patient must be in bed. In a mild, a severe, or a long-standing case of sciatica no remedy is comparable with that of rest. But rest does not mean lying down or attending to one's affairs with the aid of a conveyance; in the treatment of sciatica rest means complete relaxation of both mind and body. It means that the patient shall give himself up absolutely to taking care of himself; it means abandonment of his business, exile from his well-meaning friends and, most important of all, it means bed. A specified time should be agreed upon; a systematic and complete rest cure insisted upon. Once in bed, the leg should be so arranged as to receive the greatest amount of rest; if necessary a splint or a cradle may be adjusted so as to keep it easy and quiet.

Protect the leg from changes of temperature; this can best be brought about by flannel or woolen pajamas and socks. It is not necessary to cover both limbs; one leg of a pair of pajamas may be cut off and worn. All along the course of the nerve pack a series of hot water bags and bottles. If there are particular points of pain great comfort and aid can be derived from an electric pad. Through this a steady and continuous current can be run; in this way may be attained an even and uniform degree of heat.

The bed, when the circumstances warrant and the condition is sufficiently grave, should be a water bed; the sheets, not linen, preferably cotton. The environment is all important—quiet, attractive, and free from disturbing influences.

Next to absolute rest the one agent which is most serviceable and valuable is counterirritation. This can be applied in many ways—in the form of antiphlogistine, cantharides blisters, mustard, painting with iodine, and ironing. Ironing has many advantages; it not only applies heat, but also massage. Iodine is of value, the best preparation being Churchill's compound tincture. Of all the several counterirritants, however, one stands out pre-eminent; it gives the best results, and the least trouble. I refer to the Paquelin cautery. Apply it daily with skill and dexterity. He who applies the cautery should first learn to cauterize, and yet not burn tissue paper. Apply the cautery along the entire course of the affected nerve, leave spaces between the marks so that on the following day they too can be burned. Apply it daily for several times.

A suppository composed either of opium or one

of its alkaloids is a small adjuvant, but one which it is well to bear in mind.

Electricity is recommended by many. It is given in two forms, the Galvanic or high frequency. Either of these, in my opinion, is of doubtful value. The high frequency current can have but little effect, save from a psychic point of view. The galvanic current (3-5 milliamperes should be given) may serve, but to no great extent. It has always seemed to me that in the treatment of sciatica electricity occupies but a small and insignificant position.

Under the head of local applications I want to mention blood-letting methods. These may at times produce a very remarkable effect. They may be applied in one of two forms, either as cupping or with leeches. Apply them over the point of pain and allow them to remain for some time. Local sprays are frequently spoken of; they afford relief, but it is transient; they should be regarded more in the light of placebos than curative measures.

Much has been written in recent years of the injection method. This, by no means a modern form of treatment, dates back more than half a century. It was in 1853 that it was first presented by Wood, of Edinboro. For a number of years after it was much in vogue and then lapsed into disuse until about seven years ago, when Lange, of Vienna, revived it. Later it was modified by D'Orsay Hecht. The method consists of injecting into the sciatic nerve about 100 c.c. of normal saline solution at the body temperature and under considerable pressure.

The original method has been modified in many ways. Cocaine, stovaine, and eucaine have been added to the salt solution. For normal salt there has been substituted salts of magnesium and of sodium. Nothing, however, has proven so satisfactory or so lasting as the normal salt solution. The best plan is to inject about 100 c.c. of normal salt solution into the nerve under considerable pressure.

There are two points at which the injection may be made: If the pain is below the knee inject the peroneal branch, where it comes off from the parent nerve. If the pain is above the knee, inject the main trunk where it passes over the spine of the ischium, immediately after leaving the pelvis, through the great sacrosciatic foramen. At this point it passes between bone and muscle. The advantages of this point of selection are numerous; the point is easy to locate, it is unusually high in the course of the nerve, it is a point apt to be affected and the bony floor over which the nerve rests serves as a guide as well as an indication that the needle has passed through.

Forscheimer gives the following rule for locating this point: "Measure from the middle of the sacrococcygeal junction to the upper end of the posteroexternal border of the great trochanter. Mark the junction of the inner and middle thirds of this line, then go one inch further out." Again he says: "It also lies on a line joining the posterior-superior spine of the ilium and the tuberosity of the ischium at the junction of its middle and inferior thirds."

He gives the following technique for the injection: Sterilize the skin with soap and alcohol, paint the point chosen for the injection with iodine. Anesthetize the point and the tissues immediately beneath it with a few minims of cocaine from a hypodermic needle. Then with the patient either in the knee-chest position or preferably lying flat on his back insert the needle slowly but steadily. The needle should be about four inches long and the syringe metallic, capable of holding about 100 c.c. A shooting pain will tell when the nerve has been reached. The fluid should not be injected until this phenomenon has been experienced. Seal the puncture with collodion and keep the patient in bed for a day.

In contrast to this method are the alcoholic injections. These latter consist of the introduction of from ten to fifteen c.c. of a solution of alcohol into the sheath of the nerve. Formerly it was considered to be of much more value than at present. It should be borne in mind that the sciatic nerve, being wholly a motor nerve, the injection of alcohol produces a condition of degeneration and motor-paralysis. The consensus of opinion, therefore, is that in sciatica injections of alcohol are unwarranted.

Hot air has been tried and in some instances has relieved the pain. At Harrowgate, England, the affected leg has been subjected to an atmosphere of 350° Fahr.; some relief has been obtained but in general the result has been disappointing.

Mud baths have been tried by men in many places; this form of treatment is not practicable, and even if it were such results as have been achieved have not warranted essaying the treatment.

Baths of all kinds are without doubt of a certain benefit. These may take the form of showers, douches, needle, and medicated baths. The best of all is the hot sulphur immersion bath. This consists of placing the leg in a hot bath to which sulphur has been added. The objection to this mode of treatment is that in private practice it is extremely difficult to arrange in a satisfactory way any kind of a bath. It necessitates great quantities of hot water which should be kept at an even temperature and also requires constant handling and moving of the patient. The result is that the effort of getting a patient into and out of a tub often undoes the advantage gained by the prolonged immersion. At best any bath form of treatment is slow, tedious, and uncertain.

Hypodermic injections are frequently recommended and do relieve pain. Such relief as they give are transitory, add to the burden of the patient, owing to the elimination of drugs, and, above all, tend to inculcate a habit. The two drugs which may be injected are cocaine and morphine. The former in doses of one-tenth to one-half a grain and the latter in doses of one-eighth to one-half. These are not only unsatisfactory but dangerous methods, should be tried only as a last resort, and, if tried at all, should only be administered under the supervision of and by the physician. There is absolutely no excuse for allowing a patient to administer to himself a hypodermic for the relief of pain in sciatica. No nurse should be allowed to give it, only a physician. He should give it very exceptionally.

Massage has been frequently tried; at times with good results. The value is dependent upon the cause and the type of the sciatica. If the condition is one in which there is marked congestion, gentle, steady, and persistent massage will help. Ichthyol instead of cocoa-butter seems to exert a specific influence for the good. The very strong and disagreeable odor which accompanies the use of ichthyol is an argument against it.

Surgical measures are largely restricted to stretch-

ing the nerve. This, like many of the other procedures which I have mentioned, should be relegated to the list of remedies "of last resort."

So far as concerns medication, the list of drugs tried in sciatica is very large. In those cases in which no marked cause is discoverable methylene blue has been recommended. Castor oil is another favorite; it is always of value, as it seems to reduce the congestion and remove the toxemia. Large and repeated daily doses of strychnia help by increasing the resistance, improving the nutrition, and toning up the nervous system.

The most important thing of all is to keep the general health of the patient as near perfect as is possible. To bring about this result, resort should be had to nerve foods, tonics and stimulants. The glycerophosphates, strychnia, and alteratives are of use.

Diet is a detail which to my mind has never received sufficient attention. Any patient who is suffering acute pain and upon whose nervous system great and constant demands are being made requires a large amount of food, and nourishment of a kind which is both stimulating and fat producing. A part of the treatment of every sciatic should, therefore, consist of a diet in which fats predominate. He should have milk, cream, eggs, butter, marrow, bacon, and oils, mayonnaise dressing, and cheese. He should have frequent feedings between meals in addition to three regular and large meals. Forced feeding is almost as essential as rest. The principal foods which are contraindicated are those abounding in the proteids. Therefore meats, especially the red meats, must be eaten sparingly. Alcohol should be interdicted. Large quantities of water aid in two ways, by tending to improve general nutrition and by flushing out the kidneys. An excellent plan is to give these patients half an hour before each meal a large cup of hot water into which has been poured one of the glycerophosphates.

Now I come to a part of the subject which is very important—the after-treatment. The treatment of a condition like that of sciatica is only successful when minute attention to detail is assured. Those cases, and they are numerous, in which relapses and second attacks occur just as the patient is about to recover, or has been discharged, are, in a large measure, the results of faulty or careless after-treatment. It is unwise to discharge a case too soon, it is unwise to adjudge a case cured simply because the patient ceases to suffer. Bear in mind that a cessation of the pain does not mean that the nerve is wholly free from congestion and inflammation. A large nerve like the sciatic which has been exposed to a long siege for months afterwards, remains susceptible to fatigue, to exposure, and to changes of temperature; it is more readily affected by toxins, by diet, and by prolonged exercise. Therefore, see to all these details, keep the sciatic nerve nourished, see that it is not pressed upon, cover it, and protect it from draughts and exposure. Do this for some months after the pain has ceased and in this way give it every possible chance to get well. A practical point to bear in mind is, that no sciatica is cured until Lasègue's sign can be elicited without giving pain. I mean by this that no sciatic patient is ready to be discharged so long as flexion of the thigh upon the abdomen with the leg fully extended continues to give pain. This is a very sure help, one which you would do well to remember and one which you ought to practise.

Finally in the after-care do not forget that constitutional treatment is important and necessary; here fat producing foods and cod liver oil will be of most help.

There are a certain number of long standing and intractable cases in which no cause can be discovered and in which no treatment has helped. These cases suffer a great deal of pain and a great deal of inconvenience. The best way to manage such cases is to make a complete change of their environment, to get them away from home and friends, to give them a nurse, and to treat their general health. Such patients should be given to understand that time is the most important factor in their care and that many methods will have to be tried. In these cases I should advise a treatment consisting of rest, the saline injections, and building up of the general health. It is surprising what results can be obtained even in the chronic and long-standing cases by such methods.

In conclusion I wish to thank you for the honor you conferred upon me in inviting me here to-night and for your very kind attention.

54 West Fiftieth Street.

## DIETETIC HABIT AND GASTRIC FUNCTION.

By CHARLES SUMNER FISCHER, Ph.D., M.D.,

NEW YORK.

It is generally assumed that the question "What shall I eat?" when put to gastrologists, should be answered with facility. Simple as the question is and natural to those immediately interested, it is one of the most difficult to reply to promptly, in any given case. Hesitation usually implies either ignorance or mediocrity to the average mind. Many of us can testify to this with embarrassment, for with all due respect to the progress made in the physiology of the digestive processes during the past generation, not one particular dietetic scheme has been evolved which will meet the requirements of the general or average run of common gastric disturbances, and aid the physician to answer quickly and with assurance, the question so concisely put. The enthusiasm which prevailed in the youth of this specialty led to the elaboration of the most enticing dietetic measures and lists, devoted to this or that organic change in the stomach, scientifically conceived according to individual interpretations of analytical values, calculated with precision as to acid percentage or caloric worth; but not one of these has stood the test of time or can help any of us to determine quickly the proper procedure in any individual case. In order to be convinced of this, we have only to listen to the banal, evasive, and indifferent answers given to the question in any one of the gastric clinics.

It is not necessary to go very far to seek for the causes of this inadequacy. The elaborately detailed diet lists which appeared in such profusion during the development of this particular subject received their inspiration from enthusiasm resident in the various lines of experiment at the time. An examination of the literature will reveal that there was a period of carbohydrate preference and a period of protein preference, each for the purpose of influencing the gastric secretions. Both schools contained the names of prominent clinicians whose reputation for scientific precision could scarcely be questioned. It was the period of trial and experiment, and it remained for time to decide. The accumulation of

evidence over the years has amply demonstrated, however, that it is useless in the average case to try to change an established gastric secretion by any particular chemical property of food, at least, within periods of ordinary observation. Abnormalities of secretion, once established, are more or less fixed, no matter what improvement in symptoms may occur, and the whole object of treatment should be to accommodate the organism to the conditions. Even the radical changes induced by operation cannot alter the local tendency, a fact which has been repeatedly proved by gastric analysis in numerous cases, years after gastroenterostomy. Deficient secretion as a result of cell degeneration, cannot be restored, and protoplasmic habit and memory operate to the same end in excessive secretion. In addition to this, we now know that the great majority of the gastric abnormal secretions are not due to dietetic indiscretions and abuse as was formerly supposed, but are rather unavoidably induced by circumstances over which, in most cases, the individual has no control. Herein lies the secret of the failure of elaborate dietetics. This is the reason that the simple question, "What shall I eat?" resolves itself into one of the most perplexing with which we have to deal.

In view of the inefficacy of dietetic measures, selected as to chemical affinity, markedly to influence the gastric secretions permanently, it would seem necessary to attack the problem from another quarter. This appears all the more reasonable since clinical experience has led us to believe that the vagaries of the gastric acid secretion are of secondary importance in the sum total of casuality in diseases of the stomach. The clinical experience accumulated in the last twenty years enables the gastrologist to view the subject with broader comprehension, and to discard those minute differences of gastric function which at one time seemed so important. We have passed the period when the determination of such conditions as hyperchlorhydria or hypermotility represent the final effort in diagnosis. We look beyond the local situation and use it only as a sign post indicating the infringement of physiological or constitutional laws. Except in the very small percentage of abnormal functions, due to direct abuse of the digestive tract, most vagaries of gastric secretion represent in the individuals possessing them, indications of constitutional taint, be they metabolistic, evolutional, or temperamental. It is in the appreciation of these that real comprehension of the local conditions lies.

The secret of the successful dietetic management of most dyspepsias consists in methodically meeting these conditions and adapting the food supply thereto. Hence the question is not so much "What shall I eat?" as "When shall I eat," or "How shall I eat." Such a modification does not, as a rule, satisfy the demand or the interest of the individual concerned, for the close relationship of chemical affinity of food to distinct gastric symptoms, is an ingrained conception inspired through generations of habit and false association. We all know how difficult it is to combat this association of specific insult to specific distress, and with what incredulity any suggestion to the contrary is met. In this respect the dietetic management of most cases amounts to a process of reeducation, eradication of false notions; in short, a psychological readjustment to existing conditions. It was an old maxim of Trousseau that individual judgment in the course of experience would satisfactorily adjust the diet of the individual to the individual. While this may be true in some cases, we also know that the temporary disagreement of any particular item of food will induce in certain hyperaffective individuals an antagonistic psychological setting, calculated to produce disagreeable digestive results indefinitely. This would further lead to the conviction that in dealing with many of the indeterminate varieties of gastric disturbance, we have to do with distinct phobias, engendered by the primal instinct of self-preservation, of which hunger and appetite are but partial impulses.

The estimate of the value of our present knowledge of dietetics will depend largely upon the point of view. If we regard the subject in the light of scientific research we must feel encouraged. The work of the metabolists along decided chemical and physical lines is far reaching. If, on the other hand, we approach the question from the purely utilitarian standpoint and attempt to apply the principles so far proposed to the daily routine of actual practice, where do we stand? From not one book of the many written upon the subject of dietetics or gastric diseases can the general practitioner glean a practical scheme calculated to meet promptly the demands made upon him in any particular case. At best he receives but a hazy conception of the dubious importance of carbohydrate or protein regulation in the event of exaggerated or diminished analytical findings.

There are two aspects to the dietetic management of every case of chronic dyspepsia. There is the distinctly personal or psychological side, and there is the scientifically determined side. In the one, treatment is entirely individual. In the other, it is more or less schematic, according to the classification of the local conditions. Successful treatment will depend upon a judicious combination of the two. Undue exaggeration in either direction will result in failure. Unfortunately, such exaggeration exists all too frequently, especially on the scientific side, with the result that the human stomach is regarded as a chemical laboratory or mecahanical device which can be forced to correction by corresponding methods.

It must be evident to those having sufficient experience that there is a great number of indeterminate gastric conditions, which cannot be classified, and which cannot be reached by either physical or chemical procedure. To approach these cases from the purely scientific side would be useless. Nowhere is this more apparent than in their dietetic management. There is here a very large personal factor, involving ingrained tendency, which, if scientific dietetics does not regard it, will surely render all its efforts futile. It is here that the finest psychological insight it required. It is not sufficient in these cases to classify them as simply neurotics and to place them upon a hypernutritive diet, in the manner of frequent feeding or to subject them to the usual institutional hydrotherapeutic measures. These cases require the keenest psychological analysis, for they are not neurasthenics or psychasthenics, in the ordinary acceptation of these terms. Most of them belong to the distinct category of the anxiety neurosis, and as such, demand a complete exposure, not only of their daily routine as regards diet, work, and recreation, but also of the oftentimes hidden mental mechanisms inspiring their motives, habits, and general psychological trend. It is not to be understood that in these cases the local organic changes can be ignored. These may be very decided and require the appropriate treatment of the books. What must be remembered is that each one of these indeter-

minate cases represents a psychophysical parallelism which the present mechanical tendency in gastrology is only too willing to ignore. So great is the demand for specific chemical or mechanical procedure to meet the local conditions that the average gastrologist is afraid to acknowledge the neurological features of a case, because it might involve him in a confession of ignorance.

It is fairly safe to assume that the result of abuse of the stomach from the ordinary standpoint is not directly proportional to the amount of abuse, but is directly proportional to extraneous circumtances. It is the latter which determine the character of the local changes largely and which also cloud the issue as regards positive diagnosis. Hence it follows that the most difficult cases—difficult as to diagnosis and treatment—are found among those classes where the struggle for existence is keenest, where adjustment to the environment, in its broadest sense, is impossible, because the environment is constantly changing. Here we find that great mass of indeterminate cases, mixed psychoneurogastric conditions, which may well require the services of gastrologist, neurologist, psychologist, and sociologist. This is not so apparent at the extreme ends of the social scale. Here the results of abuse of the stomach are more directly proportional to the amount of abuse, and it is astonishing to what extent this abuse may be carried without producing symptoms. Examination in these cases will often reveal the most decided and extensive local abnormality. The impunity, however, is only apparent. The effects are there, but they are not in evidence. The reasons for this are obvious, for they lie in the sphere of affectivity, which at the opposite ends of the social scale is relatively dulled, each for its own specific cause.

Every chronic dyspeptic represents a psychological problem. It is not sufficient to be satisfied with the diagnosis, neurasthenia, or psychasthenia. In the majority of the conditions the real causes lie far deeper than the superficial atmosphere designated by these terms. The causes operating to produce the necessary affectivity are to be found at the very foundation of the individual's being. His primitive instincts are involved. In these cases it is his instinct of self-preservation, from which philosophers tell us all the baser qualities of human nature spring. Education, with resulting intelligence, does not seem to help much in guarding against such affectivity. The veneer of this is soon rubbed off by the force of impulse. Judgment is warped by emotivity. Hence it is clear why the conflict which is constantly raging in the struggle for existence should primarily affect those organs which represent for the individual the only basis of his continued existence; namely, his food supply or nutrition. It is immaterial whether the initiative for the local condition in the stomach was originally given by the habits of the individual, forces over which he had control, or his environment, over which he had no control. The final result will be the same. It is the business of the gastrologist to grasp fully the principles here involved, to shake himself free from the idea that attention to these details involves a confession of ignorance. Every accomplished gastrologist has got to be a psychologist and neurologist. The three departments go together. They are inseparable, and only with this equipment can he successfully approach those unclassifiable cases which form the great bulk of our chronic dyspeptic conditions. In this connection it would be reasonable to venture the opinion that the modern psychological neurologist, who has equipped himself with a practical working knowledge of the principles of gastric functional processes and their pathological tendencies, would be better able to approach these cases successfully than the gastrologist himself.

The general character of these cases would seem to indicate that such individuals are living in an atmosphere of tension. Psychic tension, characteristic of the age, results in physical tension, which, if projected into the gastric area, produces hyperactivity of all the functions. Hence the great frequency of such conditions as hyperchlorhydria, hypersecretion, and hypermotility. Most of these conditions are the local manifestations of anxiety states. They are preferably localized in the digestive area because most of man's activities are subservient to his animal demands. They are aided and abetted by the daily habits of diet, imposed upon the individual by necessity in some cases, more likely, however, as the result of false notions of utility or imitation of common pernicious practices. It is the latter which interest us in this connection.

It has been said that Americans do not eat; that they stoke. This criticism is justified, for it is certain that the average daily dietetic habits in this country are not adapted to the demands made upon the organism by the exigencies of life here. Until habit is adjusted to these demands there is going to be no diminution in the common forms of gastric disturbances as we encounter them in the great mass of our digestive troubles. That this will be accomplished in the near future is not probable, for the psychological setting of the average American is not conducive to this end. Living and working as he does, in an atmosphere of constant tension, let us see to what extent the daily habits of diet of the average business man would offset this tension. Breakfast is usually hurriedly taken, between seven and eight in the morning, and is of such quantity and quality that it has left the stomach in two to three hours. Hence the average worker continues to labor under conditions of tension for two hours, at least, upon an absolutely empty stomach, one which, in all probability, already exhibits excessive acidity and motility. Under these conditions of inadequate physiological and psychological receptivity, a quick lunch is indulged in. This has left the stomach by three or four o'clock, and labor is continued until the end of the working day under the same conditions.

Arrived at the usual dinner hour the average individual, exhausted and laboring under accumulated tension, exhibits one of two tendencies. He either has a voracious appetite or no appetite at all. This is the purely psychic aspect. Actual hunger is present in each case. In the first condition a hearty meal is indulged in and the stomach which has been in a condition of tonic contraction since early morning is suddenly called upon for complete relaxation to receive a large quantity of food, of promiscuous quality, and rarely selected for digestibility. If the reflex mechanisms are in proper working harmony, this may be accomplished without undue disturbance. The chances, however, are that the same conditions of habit, environment, and occupation, which have necessitated the daily routine, have already interfered with the necessary reflex regulation of adaptation by relaxation, so that instead of complete adjustment to the new conditions, there results insufficient local muscular relaxation, giving

rise to the common symptoms of pressure, bloating, and general gastric discomfort. These are evidences of muscular inability to meet the new demands. During the night the stomach gradually becomes master of the situation and the symptoms disappear. It is possible that no harm may result, but the chances are that the foundation is being laid for a permanent hyperchlorhydria or hypermotility. The general nutrition need not suffer under this régimé, for the organism may receive and assimilate its demanded food values for the twenty-four hours.

In many cases, however, the persistent gastric contraction imposed by such a régimé of irregular and insufficient food distribution, results in loss of desire for food. The individual is hungry, but has no appetite. The one is a metabolistic, the other is psychic. The inspiration for the latter comes from the contracted stomach from which the impulse is carried to the centers. It is to be inferred that at some period of the day, in these individuals, the tonic contraction of the gastric musculature was such as to inspire the psychic condition—appetite. Habit and occupation, however, prevented the satisfaction of the desire, with the result that the afferent impulses lose their effect upon the centers as a result of overstimulation. The receptivity of the centers is dulled and anorexia results. These are the cases of rapid satiety or anorexia, which present such a difficult problem for the gastrologist.

In these cases there is no corresponding local muscular relaxation to the food intake. Hence the quantity of food consumed is inadequate, and the general nutrition suffers. In addition, the tension of the day is not relieved, which leads to nocturnal restlessness, disturbing dreams, awakening without a sense of refreshment. The vicious circle is complete—prolonged abstention with hypertension, anorexia with insufficient nutrition, hypertension with local hypersecretion, and hypertonicity. It must be evident how futile it would be to approach these conditions from the purely gastrological side. Hyperchlorhydria, hypersecretion, and hypermotility existed in these individuals long before any exhibition of local discomfort. It is very probable that they exist in a majority of individuals under present conditions of life. They are not pathological until general affectivity makes them so, and this period arrives early in some, late in others, never, in a great many instances. Just as we find achylia persisting through life without declaring itself, so these conditions may exist indefinitely without attracting attention. When they do give evidence of their presence, this is not due to their own intensity, but is rather due to the increased affectivity of the individual. Local nerve irritability may remain unchanged. The individual becomes more receptive for such impressions. It is curious to note that in all the work done in the minute differentiation of the various kinds of hyperchlorhydria or hypersecretion, not one satisfactory explanation has been forthcoming as to local causation. Self-evident mechanical conditions are excepted. All publications usually end by referring to general states, such as neurasthenia or psychasthenia. Nor has one successful scheme, medical or mechanical, been devised for successfully combating these conditions from the purely local side. We have various palliative measures, good so far as they go for local relief, but the real object of treatment must always be to get the individual back into such a mental and physical condition as existed at the time when the local state passed unrecognized.

If the prevalence of such local states as excessive secretory and motor activity of the gastric structures is due to the prevailing routine life, and if this routine is unchangeable under present exacting conditions, then in the spirit of preventive medicine the dietetic habits of the day should be changed, should be so adjusted to the unavoidable conditions that the evil effects of the latter may so far as is possible be obviated or lessened. The whole object of food intake should not be ample nutrition solely, but should be directed toward lessening the psychic tension under which most individuals exist, and by relieving this, prevent the local results of such tension. It has been our habit to do this after the local harm has been done. Hypernutrition by frequent feeding is resorted to after the gastric conditions are established, but as a preventive measure for combating the production of these conditions in individuals, whose occupation and enforced habits of life would lead us to believe that the conditions will sooner or later be developed, nothing or little has been done.

In this connection we must consider metabolism to a certain extent. It is the prevailing custom to attempt to adjust the nutritive value of the food intake to the weight and the daily habits of the individual. There are very comprehensive tables to help us in this respect, and they are undoubtedly serviceable in the management of armies or in institutions, but the average practitioner finds himself peculiarly helpless in their presence. He has his choice between the sixty grammes of protein *per diem*, according to Chittenden, or the hundred grammes *per diem*, according to Atwater. He may calculate on the basis of sixty-five calories for his patient asleep, and two hundred and ninety calories for active muscular work, but unless he takes into consideration the personal factors in each case, the schematic work of the calorimeter may well be vitiated, and usually is. Much safer is he to take refuge in "Factors of Safety," assume that under the present conditions of psychical and physical tension, the individual is undersupplying fuel for his enforced energy production and feed him liberally, trusting that the organism can take care of the waste. Atwater undoubtedly had this in mind when he considered that the average American required more calories, according to body weight, than the average European, because the American throws more energy into his work. This applies as well to mental as to physical work. We have not attained the philosophical spirit on this side. We think tumultuously, and there can be no doubt that the metabolism attendant upon this phase of existence is very considerable, however small the exact calorimetric data may be so far.

The secret of successful dietetic management of the prevailing type of digestive disturbances lies in adjustment. In most cases the food intake, in both quality and quantity, is adequate for the individual. Its distribution is wrong. A quantity of food, sufficient for the caloric requirements of the body for twenty-four hours, can well be taken at one meal. It is not likely that many would perform efficient service under such a régime. Such belongs to the predatory animals. In a general way it may be said that the greater the psychic strain, the more general should be the food distribution. He whose labor is entirely physical can well survive prolonged interprandial periods. Here the exhaustion is more gradual, more cumulative. The exhaustion attendant upon mental effort is irregular. It increases

and diminishes, according to conditions, at various periods of the day. Hence the individual needs more frequent support and the response to this is more rapid. The relief here afforded is not due so much to the nutrition involved, as it is to the relaxation induced from the hypertension under which the individual is laboring. It is this relaxation which is beneficial in most cases, both generally and locally. Much labor has been expended in calculating the quantity of proteid, carbohydrate, and fat for certain body weights and amount of work performed. Very little consideration, however, has been given to the quality of the latter. It is evident, however, from observation of the general run of gastric diseases, that it is the latter which has not only induced the local troubles, but also determined their character, and we can expect very little diminution in their frequency until this proper adjustment is made. This applies as well to the factory worker as to the office worker. In the one case it is the extreme tension of occupation; in the other, its extreme monotony. Both these factors are decidedly operative in neurology as conducive to abnormal nerve states. Physicians from the industrial districts report the frequency of the neuroses among their people. If the neuroses are frequent, it is safe to assume that the gastroses are frequent. Here the increased meal system would not only benefit the local conditions, but, by relieving the monotony of the occupation, would do much to prevent the increase of the minor nervous states. The treatment of a great many of the so-called dyspeptic troubles, the vague, indeterminate cases which do not yield to routine methods, is simply a question of intelligent regulation and adjustment to existing conditions. In this respect an imitation of European customs would serve a certain purpose, and many a case of the class referred to would be relieved and benefited by a *déjeuner à la fourchette* or by some afternoon tea. Nor would such a régime reduce the productive activity of the individual. On the contrary, it would increase it. The quality of the output would be improved, for most of us are working under conditions which are not conducive to the best that is in us of good judgment, concentrated attention, and undisturbed mental poise. For most people, under present conditions of life, there exists a very decided disturbance of relationship between cognition, affectivity, and conation, and while we cannot change conditions as they exist, we can do much in the daily regulation of the individual to adjust him to these conditions. This is the greatest, the most productive, most satisfactory work the gastrologist can perform. This requires oftentimes much patience. It entails not only an inquiry into the individual's habits, occupation, and environment, but also a searching investigation of his general attitude toward life by an analysis of his sentiments into underlying emotional complexes, these further into their propelling primary instincts, and a selection from these of the one which is the driving impulse of the whole of his existence. It can be fairly safely assumed that in each individual there is one selective and compelling primitive instinct, around which the character of the individual is crystallized, and which is the dominating note of his personality.

If this overdetermined instinct assumes such proportions as to bring it into conflict with the herd instinct which manifests itself in the social restriction imposed upon all by the conventions, an emotional conflict will ensue, which, being itself primary in its nature, will naturally first affect those bodily functions which stand in closest relation to the primitive instinct of self-preservation, which is partially revealed as appetite, resulting in food consumption. Every gastrologist should be a psychologist, to a certain extent, for there is a vast number of digestive conditions which will not yield to the cold scientific attitude assumed by those who look upon stomach diseases in the light of purely physical and physiological causal relationship. In philosophy he should be a hedonist, for whatever may be the merit attached to this conception of inspiration for human activity, there can be no doubt that this principle is always involved in the proper estimation of the condition with which we are here dealing.

It is not to be inferred from the foregoing that the actual local conditions of secretions and motility are negligible in the dietetic management of our ordinary dyspepsias. The proper diet, while striking at the root of the evils as they exist in the habits and environment of the individuals, must seek a compromise between the local effects and the general causative agencies. The local effects are primarily increased or diminished secretion, of which achylia and hyperchlorhydria are the extreme types; hypomotility and hypermotility, of which atony and hypertonicity are the best examples. These fundamental states, or the tendency to them, are present in every case, and the question arises how far can we influence them through the diet. In a general way, it may be assumed that they cannot be materially influenced by the diet because in the great majority of cases they have not been produced by the diet. It can further be stated, especially of the secretions, that once firmly established in their abnormality, they have come to stay. Hence a rational diet must adapt itself to the condition and make the best of it.

In this regard it would be interesting to inquire whether the chemical attributes of food have any particular bearing upon these states. Much work has been done along this line, and it is generally assumed that carbohydrates diminish gastric secretions and that proteins stimulate them. Under given conditions of experiment this principle seems to hold true over short periods of time. In practice it has been of indifferent service. There are three reasons for this: First, it does not strike at the causes of the abnormal secretion. Second, any monotonous diet loses its effect in the course of time and fails in its object through lack of variety. It has been experimentally demonstrated that the hyperstimulation of proteins, if continued long enough, will end with hypostimulation. A bodily sensation is the result of variety of stimulation, and the perception of any sensation, be it visual, tactile, or organic, will diminish if the exciting cause continues undiminished and unchanged indefinitely. The best practical example of this we have in certain cases of overstimulation from food retention in the stomach, in the early stages of which we often encounter excessive acid secretion. As a result of continuous irritation, this hyperacidity may change to hypoacidity. It is a fictitious condition, for removal of the retention will alter the secretory function. The third reason for failure to secure the desired theoretical result of either a carbohydrate or protein régime rests with the motor functions. In achylia we cannot give proteins because there is no acid to prepare them for intestinal digestion, and the usual hypermotility results in sudden overloading the upper intestine with a mass of material with which it may be dif-

ficult to cope. In hyperchlorhydria we cannot give proteins because of their hyperstimulating qualities, resulting in excess of acidity which in the hypermotility resident in the common combination of hyperacidity and hypermotility, in the early stages, produces the same overloading of the intestine, except that here it is complicated by an excessive acidity. Further, it must be remembered that the ultimate tendency of every hyperchlorhydria is toward retention, which can only be hastened by a protein diet.

Similar difficulties present themselves in the case of the carbohydrates. In achylia these would seem to constitute the ideal diet. While they may be better digested in the subacid stomach, they lack also the necessary stimulating quality with which it is desired to revive the flagging secretion. This cannot be accomplished by the carbohydrates for their appeal to the appetite is small, so that the very important factor of the psychic secretion is eliminated. In hyperchlorhydria the administration of carbohydrates may yield less acid, but experience teaches that they are not well supported on account of their tendency to excessive fermentation. The ordinary yeast plant flourishes in an acid medium and with the tendency to retention which supervenes in the course of time, the local conditions for fermentation become increasingly favorable.

Hence it is evident that in actual practice there are very decided limitations to the employment of scientifically conceived dietetic régimes. The difficulties enumerated above constitute only a small number of them. The question naturally arises whether in the treatment of our common mixed forms of gastric indigestion, it is essential to lay great stress upon the vagaries of the local functions themselves, to try to influence them by determinate dietetic procedures. Experience only can solve this problem, and it appears to have demonstrated that a simple, non-irritating, rationally conceived mixed diet, distributed in such quantity, and at such intervals as to meet the requirements of general energy disbursement and local muscular activity, will accomplish the desired result in most cases. From observation we know what the general trend of gastric disturbance is, what local conditions are likely to supervene as a result of modern every-day activity. Hence the practitioner who, without gastric analysis, fully appreciates this tendency, can, by regulating the diet to meet these conditions, well afford to neglect the details of chemical affinity. For some years the writer has been employing such a method and has found that the same diet, applied with this conception, will accomplish excellent results, irrespective of ordinary local conditions of acidity or motility.

Much time has been spent and experiment indulged in to differentiate the finer nuances of gastric abnormal secretion, and there are those who lay great store by the results obtained, but when we look back and attempt to discover some differentiating causal relationship, we fail to discover the same, and the finer distinctions of such states as hyperchlorhydria (periodic or permanent), hypersecretion (alimentary, larvated, etc.) are but successive stages of one and the same process, the distinguishing aspects of which are accidental manifestations produced by differences in duration and of individual factors operating in each case. Excepting purely mechanical or gross morphological local conditions, no specific cause for each phase has been found, so that the finer distinctions made and insisted upon by some as so essential retain but a questionable interest.

In conclusion, it may be stated that as specific causes are wanting, so also specific treatments are lacking, and having satisfied our scientific vanity as to finer distinctions in local manifestations, we are forced, when it comes to treatment, to indulge in the broadest kind of generalization. This is as it should be, for the causes of most of our common, mixed, indeterminate stomach troubles are general causes, without specific relationship to local conditions, intimately connected with the personality of the individual in all that this implies, and the gastrologist who fails to go beyond local considerations, who applies himself too assiduously to chemistry and physics, has failed to grasp the situation.

144 East Thirty-eighth Street.

## THE ECONOMIC IMPORTANCE OF SPEECH DEFECTS.*

By IRA S. WILE, M.S., M.D.,

NEW YORK.

In the evolution of species the origin of speech presents numerous interesting problems. From the stridor of insects to the croaks of frogs or the barks of dogs, there is a gradual development of vocalization until, in the gibbon, there arises the first evidence of musical direction of voice. Speech is an instrument for the communication of ideas. In its broad utilization, speech constitutes a marked characteristic of homo sapiens. As man is essentially a social animal, so speech is his most important social characteristic and activity.

The capacity for speech exists at birth. The acquisition of language and the development of tone production depend upon training through the various senses. Speech may only be acquired through the harmonious action of the brain and the muscles. Cerebration and muscular coordination are prerequisites for the verbal crystallization of the ideation which is seeking expression. Speech in its essence is a conscious act. It originates from a desire or impulse to express ideas or communicate thoughts. Born of emotions it is intellectualized. "Speech was made to open man to man, and not to hide him, to promote commerce and not to betray it."

Sad is the lot of the mute. Woeful and pitiful is he until the gates of intelligence are opened and the flood of ideas may issue forth through the medium of words. The living voiceless man is stultified and the world is deprived of such richness of his mind as cultivation might reveal. In the words of Pliny, it is "the living voice that sways the soul." The value of speech from the standpoint of personal expression cannot be estimated in terms of pounds, shillings, and pence. The development of a single human being to a state of mental happiness involves self-expression. Constant self-repression is incompatible with perfect health and contentment.

The sounds of the voice were primarily used and perfected, according to Darwin, in relation to the propagation of the species. With this germinal idea one may ally the importance of speech to the development of the race. Racial progress is largely dependent upon the development of voice production and the transmutation of ideas into definite arbitrary sounds which constitute a medium of ex-

*Read before the Manhattan Medical Society.

pression. Tone production, modulation, and timbre are subordinate phases and constitute the refinements of speech. They are secondary, however, as modes of thought and expression, just as gesture and muscular movements have been relegated to a position of secondary importance. Among the deaf, the thinking and articulating mechanism may be normal and speech may entirely lack what we call expression, though it serves to communicate thought. The potentional value of such speech is less than that of normal speech because of its monotony, its strain upon the attention of hearers, and its abnormal sound. Its social value is distinctly limited, though it does serve to promote soul expression.

It is exceedingly difficult to establish with even approximate mathematical precision the economic cost of speech defects. We have no method of determining the number of people with speech defects. The economic importance of speech defects depends upon the functional ability of individuals, and at various ages the importance of the same speech defects varies. It is obvious that the importance of a speech defect in a child of five is less than in a man of twenty.

It is almost impossible to consider speech defects as isolated phenomena. There are no careful estimations of the number of individuals who suffer from speech defects without some complication of an organic or functional derangement, such as produce important factors in lessening the economic value of the individual. Obviously speech defects among the deaf and the feeble-minded constitute only a part of the lessening of the economic work and the speech defect must be considered simply as a part of the general disability which lessens the social worth of the afflicted.

All speech defects represent abnormalities. In a wide sense abnormal children are "those afflicted with anything whatever that unfavorably affects their lives in relation to the social medium in which they live." Consequently speech defects represent abnormalities which per se limit the possibilities of children and adults to realize to the utmost their potential power for uniting in the activities of the world.

Speech defects involve the disabilities due to some error in the mechanics of tone production, some inco-ordination in the muscular habit of sound production or faulty cerebration. Pure speech depends upon the integrity of the several mechanisms involved in sound or word appreciation. Speech defects in their origin may be acquired or congenital. In their pathology they may be central or peripheral. According to Makuen "speech is an acquired faculty and stammering is an acquired defect." The child with ability to hear ordinary sounds but who lacks the ability to retain impressions of spoken language will fail to acquire speech.

Stuttering, according to Claiborne, should be classed among those conditions having their basis in a congenital defect in the centers controlling speech. A large proportion of stutterers are curable. Probably fifty per cent. of stuttering could be prevented. The limitation of the stutterer is marked not so much in his powers of acquisition and appreciation as in his ability to give physical expression to his thoughts. His mentality may be intact but his opportunities for giving evidence of his mentality are hampered by virtue of his explosive expression which deprives him of an attentive audience.

Speech defects which originate in organic diseases such as paresis and multiple sclerosis may be of value in first calling attention to the existence of these serious diseases. The value of speech defects as indicating disordered cerebration has not been fully appreciated. Aphasia, whether auditory or motor, complicates the disability of paralysis and renders more helpless the victims of the numerous conditions which produce the aphasias. The disagreeable echolalia or paraphasia present cerebral forms of speech defects which indicate difficulties with cerebral mechanisms and make it difficult for individuals to give free expression to their desires and wants. In all the aphasias, the problem of thought expression is of importance and the economic cost of overcoming the limitations of such speech defects can only be estimated in terms of nursing service, protection and re-education, which is a most valuable factor.

The various types of speech defects which are dependent upon malformations, such as hare-lip, cleft palate, hypertrophied tonsils and adenoids, and dental deformities reveal an economic loss which must include the cost of operations, nursing care, and hospital treatment. The permanent defects which result even after medical and surgical aid has been afforded circumscribe the activities of the sufferers to occupations wherein vocal effort is of minor importance.

Mutism is an unfortunate condition which received attention even in the days of the Venerable Bede. The development of attention to speech defects centers about the effort to gain an insight into the souls of mutes. According to Budin, twenty-five per cent. of deaf-mutes occur among consanguineous marriages. Consequently, the economic cost of this type of defect involves the eugenic considerations that would tend to lessen the occurrence of this defect. The cost of deaf-mutism has not been calculated because in the figures given for institutions for the deaf there is included the cost of instruction of those who are not absolutely deaf-mutes but who have various impairments of hearing due to catarrhal conditions.

The retarded development of speech indicates that something is impairing the mental and physical faculties of childhood. This is especially manifest in the relation of retarded speech to the slow development of walking. The longer speech is delayed, the greater likelihood is there of permanent speech deficiency. To this extent early speech defects or even idioglossia may serve to prognosticate mental impairment. Late talking in itself may have some slight effect upon the mental powers, limiting methods of expression, though not necessarily interfering with powers of idea appreciation. The feeble-minded child who is late in learning to walk as well as to talk is likely to be of the most severe type of mental defective.

Distinction should be made between the deaf child who has speech deficiencies because of his inability to hear and the feeble-minded child who is unable to speak because of a lack of cerebral development. This fact is of the utmost importance in regard to the problems of education, because, though these two types of children may at the time of entering school be equally backward, the methods of education to be employed must be radically different, and consequently different types of classes must be instituted for their education.

The majority of speech defects are combined with defects of vision, hearing, muscular coordination or

cerebral mal-developments. Of the twenty million children in this country it has been estimated that five per cent. have impaired hearing and twenty-five per cent. have impaired sight. It has been adjudged that some impediment in speech exists in three per cent. of the school children. There is no differentiation, however, in so far as I have been able to ascertain, as to the nature of these various impediments.

The character of speech defects and their importance varies according to the degree of deafness. Mutism results if deafness occurs before speech is developed. Indeed if speech has merely begun and deafness ensues approximate mutism results. The deficiencies of speech will vary with moderate or marked degrees of deafness, though these represent types of speech defects which are most easily amenable to educational treatment. Deafness only indirectly affects the speech center but nevertheless markedly influences vocalization and expression.

Feeble-mindedness may be first evidenced by lateness in talking or by peculiarity of speech such as difficulty in giving certain consonant sounds. As has been remarked, the longer speech is delayed in its development, the more likelihood of the permanence of the mental defect. Stammering and stuttering are not usually correlated in any way with feeble-mindedness, although as Church-Peterson states, they "are certainly found more often in children with a neuropathic inheritance than in children with good heredity." The importance of this observation can be estimated by its indication of the necessity of giving particular care and attention to children in the home.

In Germany, investigation has shown that of the fifteen thousand children in special schools for defectives, six per cent. have associated speech defects. It is thus obvious that the economic importance of speech defects is bound up in considerations of the importance of such causative conditions as feeble-mindedness, deafness, and neuropathic manifestations.

Assuming that estimations by Van Sickle, Witmer, and Ayres are correct in that four per cent. of our public school children are feeble-minded, it would mean that there are eight hundred thousand feeble-minded children in the United States, although it must be appreciated that of this number only one hundred thousand are genuinely mentally deficient and should be treated in institutions instead of public schools. If, then, investigation should show that the German percentage, six per cent., would apply to all our defectives, there would be in the United States forty-eight thousand defective children with speech defects. Ninety-four cities in the United States have special classes for defectives, forty-six make special provision for the deaf and semi-deaf, and three have classes for stammerers, stutterers, lispers, and the dumb.

The economic cost of speech defects is registered in the limitations of occupations that are available for individuals who have speech deficiencies. The more pronounced the defect, the more limited the field of activity. Few employers desire deaf-mutes and their industrial situation is most difficult. Law and medicine, or even the ministry, are open to those talented individuals who have risen above their speech limitations and have been able to submerge their sensitiveness and self-consciousness so that their self-expression depends upon what they have to say rather than the way they say it.

Where feeble-mindedness is the basic condition, the occupation is naturally limited by the scale of intelligence to which the individual child can rise. In the New York Institute for the Deaf and Dumb, instruction is given in the shoe shop and tailor shop, while carpentry, printing, gardening, and similar occupations are made available. State institutions for the deaf and dumb require five to seven years of training at a per capita cost of three hundred and twenty-five dollars per year. It has been estimated that one in every twenty-four hundred of the population in the United States is a deaf-mute. This would indicate that there are about 37,500 deaf-mutes in the United States. This would mean that the mere cost of education in the state institutions for all of these deaf-mutes would cost approximately twelve million dollars per annum.

The prevention of industrial accidents requires that all workmen with speech imperfections should be kept out of positions that require quick utterance or that might involve the necessity of sudden expressions of warning to fellow workmen. The relation of speech defects to the cost of industrial accidents has been hinted at in those reports which attribute a part of the cause of accidents to the inability of employees to speak the prevailing language of the factory, mine, or shop.

The importance of discouragement, anxiety, family distress, embarrassment, diffidence, and shyness upon the development of high moral character cannot be estimated. Wherefore, among delinquents, speech deficiencies are noted with greater frequency than among the normal population. This may be due possibly to the fact that there is a greater amount of feeble-mindedness among delinquents.

According to the United States Commissioner of Education in 1910-11, there were fifty-seven state institutions for the deaf containing 10,740 pupils, only 456 of whom were of high school grade. The total cost of these institutions for one year was $3,439,101. The United States possess fifty-five public day schools for the deaf with an enrollment of 1,607 children, while twenty private schools possess 396 pupils. The single public school for the deaf in New York City registered 220 children and cost for 1909-10, $25,000.

It is important that the education of the deaf-mute should be begun early. While home instruction should be begun at two years, the child should be placed in school during the period of life when speech is most easily acquired, before seven years of age. The attempt to correct speech defects after the age of twelve adds greatly to its difficulty.

The British Royal Commission has estimated that each feeble-minded individual costs the state about ten thousand dollars. Figures relating to the number of feeble-minded individuals are mere approximations. Scotland is said to have one to four hundred of the population, England one to two hundred and seventeen, Ireland one to one hundred and seventy-five. Goddard has estimated the ratio to be one to three hundred in New Jersey. The Letchworth Site Commission concluded that there were about 12,300 mental defectives in New York State. Recent figures apparently indicate that there are three hundred thousand feeble-minded people in the United States. Feeble-mindedness with its increased mortality, particularly with the exceedingly high mortality among imbeciles and idiots, involves a decrease in the number of defectives with speech deficiencies who grow to adult life. The lower the mentality of the individual, the less resistant is the physical stamina. For this reason the number of

speech defectives to be noted during adult life is far less proportionately than during the period of infancy and childhood. To support feeble-minded individuals in State institutions costs about $161.20 per annum. The computation does not differentiate the actual cost of speech education, although it is apparent that self-expression through speech is the principal factor to constitute the mental defective a social asset.

The relation of speech defects to normal delinquency has not been determined, although it is possible to appreciate that speech defects if interpreted as closely related to mental abnormality, probably plays some part in the problems of delinquency. In 1911, twenty-seven State institutions maintained 19,672 feeble-minded at a cost of $4,202,664, while eighteen private institutions cared for 997 individuals at a cost of $301,716. In the ordinary public school system, the educational cost for speech defects of moderate degree has not been estimated. A special teacher is necessary, an ungraded class is important, and the development of normal speech must be facilitated through personal analysis of the underlying causes of the speech deficiency. It is vitally important both for the benefit of the individual child with a speech defect, and for the rest of the children in the class, that special classes for stutterers, stammerers, and lispers should be maintained with a view to developing normal speech for them.

Finally, in estimating the economic importance of speech defects, I can but repeat what I have already stated. The actual cost of speech defects to society cannot be estimated at the present time in dollars and cents. The limitations of self-expression is a loss to the individual and to the community. Speech defects which interfere with the expansion of consciousness along the lines of culture and education with a view to developing useful citizenship decrease the social worth of the individual and rob the community of the full fruits of human mentality. As a medium of social intercourse, speech is the maximum factor. Only through the voice has the history of the past, before the days of writing, been given to us. To be a normal being, normal speech is a prerequisite.

## THE IMPORTANCE AND VALUE OF THE INVERTED T-INCISION IN VAGINAL SURGERY.

By SAMUEL WYLLIS BANDLER, M.D.,

NEW YORK.

ADJUNCT PROFESSOR DISEASES OF WOMEN, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL

When a transverse incision is made in the anterior fornix above the external os below the lower border of the bladder, and through this incision the bladder is separated from contact with the anterior wall of the cervix and uterus, the vesicouterine fold of peritoneum is reached. This must be perforated or incised in order to enter the peritoneal cavity. If, for diagnostic purposes, one desires to look at this pouch of peritoneum and see if blood in the pelvic cavity shimmers through, then this transverse incision suffices. If one is dealing with a multipara and with a uterus which descends readily one may, through such a transverse incision, enter the peritoneal cavity, deliver the uterus, and do some of the various operations on the adnexa. If one is to do a vaginal hysterectomy, this transverse incision, continued entirely around the cervix, enables one to remove the uterus without abdominal incision.

If, however, one wishes to fix any part of the uterus to any part of the vaginal wall at a point higher than the transverse incision, one must separate the bladder in part or in whole. If one wishes to fix the upper part of the fundus to the lowest part of the anterior vaginal wall for the correction of cystocele or retroflexion by the so-called Dührssen method, the bladder must be separated from the entire anterior vaginal wall. If one wishes a roomy space through which to work, if one desires to obtain a splendid exposure of the vesicouterine fold of peritoneum, and to open this fold with the aid of sight, one must add a longitudinal incision to the transverse. If we wish to obtain more ready approach to the lower area of the uterus in the performance of the technically most difficult vaginal hysterectomy; if we wish to hold the bladder out of harm's way in performing this operation, and if we wish to have more room for delivering the uterus before or after morcellement, we must add a longitudinal incision to the transverse. *If we wish, after performing a hysterectomy, to attach the lateral flaps of vaginal mucosa to the broad ligaments, in such a manner as to hold up the bladder as if in a hammock; if we wish to avoid the subsequent occurrence of cystocele*, we must add a longitudinal incision to a primary transverse one. If we wish a clear exposure of the vesicouterine fold of peritoneum, in order to diagnose the existence of an ectopic gestation without opening this plica, or with opening of the plica, or if we wish to remove an ectopic gestation by this route readily, and by the aid of sight, we ought to add a longitudinal incision to the primary transverse one.

The longitudinal incision is necessary to obtain separation of the bladder from the anterior vaginal wall throughout the greatest portion of its extent. The transverse incision is necessary to amplify the area of entrance into the pelvis obtained by a longitudinal incision, but there are more important reasons for its use. With the transverse incision, we readily separate the bladder from the anterior wall of the cervix and uterus *without the slightest risk of perforating the bladder*, and we readily reach the vesicouterine fold of peritoneum, which is so important a landmark, and which is readily recognized by the sense of touch and by sight. Starting out from the middle of the upper margin of the transverse incision and with the bladder separated from the uterus, we have a point of entrance into any level between the vaginal mucosa and the bladder mucosa covered by muscularis. We know the situation of these two tissues, we know with certainty that we can cut and pass between the two, we can choose the depth to which we wish to go, and leave as much of that elastic and connective tissue, situated between the vaginal mucosa and bladder, attached to either of these two as we wish. In other words, we can make the vaginal flaps thin or thick, we can separate the bladder and leave it covered by little or much of the interposed fascia. We can do this with the various planes exposed to view. We can, by inserting the finger under the bladder, make such use of the sense of touch, that the longitudinal incision can be made of any length, and the bladder can be dissected to any desired extent *without the faintest danger of perforating the bladder*.

After all, it is the bladder which is the important preliminary organ which we have to bear in mind, and *I have no doubt but that failure to attack this bladder problem in an easy and safe manner is responsible to a great degree for the failure of many men to take up this method after observing it, or to continue it after attempting it.* The question is simple enough. Our mode of approach is between the bladder and the uterus. If we pass safely between these two organs, if we make the right sort of incisions, if we use simply ordinary care to do no injury, we have as ready, as safe and as practical a means of entering the pelvic cavity as one could possibly wish. Certainly as roomy an approach is before us as many surgeons have with their individual forms of incision in the performance of innumerable abdominal operations.

Any intraperitoneal operation finds its dangers in injury to some structure or viscus which has a lumen. If one leaves no blood vessel untied, if there is no opening (which will not heal) in intestine, or bladder, or ureter, operations on the pelvic organs are generally successful. Injury to any of these structures may occur in the performance of an abdominal operation of a gynecological nature. The same holds true by the vaginal route. If no blood vessel be left untied, if the ureters are not injured, if the intestine is not injured, if the bladder is not perforated, the operations are usually successful, so far as recovery is concerned. In other words, care is essential by either route. I hold that there is less risk of injuring these structures in the operations which I consider appropriate to the vaginal method than by the abdominal path. Aside from this, many of the operations are performed with greater ease, the patients accept this path with less reluctance. In the case of the very obese, the advantage of a possible vaginal choice is great. Besides, there are several operations, especially those designed to cure cystocele and the various degrees of descensus uteri down to the degree of total prolapse, which produce better and more permanent results than any abdominal methods yet devised. Once the uterus is exposed to view, its delivery into the vagina or the attack upon the uterus, or upon any diseased structures of the inner genitalia, is directed by the same principles, mental and mechanical, as are made use of in the performance of those operations through the abdominal wall. Since the space through which the work is done depends upon the character of the introitus and the size of the opening in the anterior fornix, we are forced to consider just these two points. As a general proposition it goes without saying that in a unipara or multipara the introitus provides a larger area of entrance than is the case with a nullipara. The same holds true of the anterior fornix where the opening which we make cannot be so large nor so readily accessible in a nullipara as is the case with multiparæ. Hence one uses judgment in selecting the favorable cases, and on the proper exercise of this judgment depends to a great degree the readiness with which the operation may be begun and completed. The more readily the cervix can be pulled down toward the vulva, the more easily may the operation be carried out. With these various considerations in mind, it is apparent that, to enter the peritoneal cavity and to perform any of the various types of gynecological operations, the bladder must be separated from contact with the vagina and uterus and must be held out of the way of injury while the operation is being done. To accomplish this separation with the greatest ease, with the greatest certainty of avoiding injury to the bladder, with the greatest exposure of the peritoneum, and with the association of the widest space through which the various steps of the operation may be performed, the inverted T-incision is a procedure of such vital importance that I can say with the utmost confidence that, he who tries it and masters it will find opened to him a variety of operations the character and value of which is only now beginning to be recognized.

134 West Eighty-seventh Street.

## SOME REMARKS ON BRONCHIAL OR TRUE ASTHMA.*

By HAROLD DE WOLF, M.D.,

THE GLEN SPRINGS, WATKINS, N. Y.

If one glances even casually at a description of asthma in any of the leading textbooks on medicine he is immediately struck by the curious fact that anything under heaven can excite an attack and conversely anything can cure it. Consequently a person with an imagination will promptly decide that a disease of such varied etiology and heterogeneous treatment cannot as yet be thoroughly understood, and he is quite correct—in a sense. Asthma has existed as a clinical entity as long as medicine itself and it is not hard to imagine that some of the curious "seizures" of which we read in ancient literature may have been the spontaneous onset of such an attack; perhaps even an occasional "miracle" may have been performed and an apparently dying man restored to health and happiness in the twinkling of an eye by someone with more intelligence than the average and a desire to impress the multitude.

Asthma may then be described as paroxysmal dyspnea, largely of the expiratory type, of more or less sudden onset, and variable though short duration. As the dyspnea is essentially of the paroxysmal type we can at once exclude from consideration such so-called asthmatic conditions as those developing in late cardiac and renal disease, and confine ourselves to true or bronchial asthma with its allies —hay-fever, rose-cold, paroxysmal sneezing, and spasmodic bronchitis of children. All these seem to have a common basis in patients of the so-called nervous or neurotic type. All are of a paroxysmal nature, with sudden onset and a tendency to recur at more or less definite intervals, and none is in itself fatal, although any may indirectly lead to a fatal issue.

Asthma is found in all climates, all races, and at any age—twenty-eight days being the youngest recorded case. Hyde Salter's series of 225 showed that over thirty-one per cent. developed before the age of ten, forty-five per cent. before twenty years were reached, sixty-two per cent. before the thirtieth year, and eighty-two per cent. under forty.

The disease can develop in either sex, but curiously enough is twice as frequent in the male, thereby being a powerful argumentative weapon in the hands of those who say that "the female of the species is less nervous than the male." While hay-fever and rose-cold have, as their names imply, a specific time of year to appear, asthma itself is much more frequent in the fall and spring. As might be expected this distressing disease appears in family groups frequently and many times, although we may not find out and out asthmatics, we at least discover

*Written for the Schuyler County Medical Society, January 28, 1913.

a neurotic tendency in other ways, such as urticaria, nervous vomiting and diarrhea, polyuria, and "indigestion," if I may be pardoned for the use of so unscientific a term.

Ever since 1872, when Voltolini started the ball rolling by apparently curing eleven cases of asthma by the removal of nasal polypi, the medical profession has been searching for the cause of this most annoying condition in and about the nasal mucosa, so far, however, with rather unsatisfactory results, although just enough progress has been made to encourage further effort in this direction. As a damper though on the enthusiasm of the rhinologist who believes he can cure it by operation, cases have been reported in sufficient numbers to make the statement true beyond peradventure that asthma is frequently developed by, or a pre-existing attack made worse by, the removal of septal spurs, turbinates, or polypi. However, both contentions can be reconciled if one exercises a little thought, it being quite conceivable that in the one case a hypersensitive area may be removed at operation, while in the other an area that has previously given no trouble may become oversensitized and excite reflexly an attack of asthma. This is partly hypothesis, but is somewhat borne out by an experiment performed by Lazarus, who was able to excite bronchial constriction by the application of a mild electrical current to the nasal mucosa. Moreover, it is well known that dust, pollen of hay and some plants, and often emanations from the cat or other animals, can bring on one of these annoying seizures.

Anatomically considered, asthma is a very simple disease indeed if we confine ourselves to it alone and leave out of consideration its results. Commonly there is found dilatation and thickening of the smaller bronchial tubes, distention of the air sacs, atheromatous changes in the branches of the pulmonary artery in the lung, and frequently moderate dilatation of the right heart. Curious masses of mucus containing eosinophilic cells and often the double pointed Charcot-Leyden crystals are constant. These Curschmann's spirals, as they are called, can be teased out or will separate themselves if placed in a glass of water and are found to be complete casts of the finer bronchial tubes and bronchioles.

As to the actual morbid conditions that can bring about such changes there are at least two theories of sufficient merit to be considered. I refer to a spasmodic constriction of the small bronchi and a rapid turgescence or tumefaction of the mucosa. The first has by far the greater number of supporters, not by any means the least among them being Hyde Salter who says in support of it: "In the first place, the sudden induction and remission of the asthmatic paroxysm is consistent with the supposition; in the second place, there is abundant proof that the air in the lungs is locked up, and cannot be got in or out; there is plenty of air in the chest, percussion is even overresonant, yet the patient is as unable to drive air out as to draw it in; he can neither inspire nor expire; he cannot discharge breath enough to whistle, to blow out a candle, or to blow his nose. The muscles of respiration tug and labor to fill and empty the chest, but the chest walls remain almost immovable; the inspiratory muscles cannot raise them, the expiratory cannot depress them. On listening to the chest we find corroborative evidence of the stagnation of air. The respiratory murmur is in a great degree lost. This absence of respiratory sound accompanied by violent respiratory effort is one of the most striking and suggestive of the facts of asthma."

How can we explain it except by supposing that there is some bar to the ingress and egress of air; and what can this bar be, unless it be spasm of the bronchial tubes? It cannot be inflammatory thickening of the mucous membrane lining them; for the sudden almost instantaneous establishment and remission of the dyspnea is incompatible with this. It cannot be mucus plugging the tubes, for the attack will often come and go without any expectoration whatever. But we have still more positive and precise evidence of the circumscribed narrowing of the air-tubes in the musical sounds that are present in asthmatic breathing. This symptom has all the certainty and precision that characterizes physical phenomena; and it shows that the air-tubes are the seat of constrictions which throw the air passing through them into vibrations and convert them into musical instruments; since the musical sounds are multitudinous, the points of constriction must be many; since they are constantly varying in locality and character, the constrictions of the tubes must be undergoing similar change. Experimental evidence, too, supports this theory, as Brodie and Dixon, in a work published in 1903, show that constriction of the small bronchi brought about by stimulation of the vagus produces distention of the air sacs similar to that occurring in asthma.

The second theory, that of temporary turgescence of the bronchial mucosa, sounds well, but histology teaches us that while the nasal mucous membrane is vascular and contains much erectile tissue, that of the bronchi is very poorly supplied with blood and could not in the very nature of things respond in the same way to an irritant. Moreover no inflammatory change has ever been demonstrated in the bronchi of a person dying during an attack of asthma.

Clinically this disease is so characteristic that it would seem unnecessary to enumerate its symptoms, but to refresh our memories and to make this paper complete in that essential, I will attempt to describe a typical attack. Usually at night, or in the early morning hours, the patient suddenly awakes with a feeling of oppression in his chest, and in a few moments he is gasping for breath. He cannot remain prone but is forced to sit up or even to rush from the bed to the open window; his head is fixed by firm contraction of the neck muscles which stand out like whipcords; his shoulders are hunched up, and his hands grasp firmly anything he can get hold of, like the back of a chair, foot of the bed, or window-sill, to assist in the tremendous effort for breath. The face is either extremely pallid or dusky red to black from accumulation of carbon-dioxide in the blood; the eyes bulge, the nostrils dilate with each attempted inspiration, and the skin is covered with a cold, clammy sweat. The pulse is usually normal and the temperature is never raised during an uncomplicated attack. Gradually the spasm relaxes and the patient sinks back into a resting posture, often going quietly to sleep after the passage of a large quantity of pale urine. During the attack physical examination will disclose a bulging chest wall which plunges but actually moves very little with each respiratory effort; the inspiration will be found short, gasping, and abortive, while the expiration is four or five times as long. Percussion is hyperresonant throughout; there are practically no breath sounds; but many soft, far-away, long-drawn-out sibilant râles are heard with each attempt to empty the lungs.

It must not be thought that such a description applies to each and every attack; this is far from the case; however, it may be said that they differ largely in degree, and under most circumstances the diagnosis is easily made. It is a curious fact, noted by many observers, that if the paroxysm lasts long enough a patient will often apparently fail to appreciate that it is over and will continue to gasp and plunge for some moments even though he could breathe with perfect ease. In this connection I recall the first asthmatic I ever saw who habitually did just this thing, and would with a start wake to a realization of the fact that she was well and would then settle back to enjoy life once more.

Hay-fever being the most common and the worst of asthma's allies deserves some mention here, as it occasionally alternates with true asthmatic attacks and is frequently found in the family groups previously mentioned. This disease is characterized by severe frontal headache, coryza, and oppressive wheezing quite comparable to that of the more important condition. It, too, is most common in early life, but is not by any means confined to young people. A physician of my acquaintance never had an attack until he was past 30, but now suffers from it during the entire summer unless he goes to a cooler climate.

The prognosis then may be summed up in a few words. If taken in time, in early life before the nervous system has, we may say, the habit, it is often possible by painstaking care to train the little patient in the way he should go and entirely cure this most distressing condition. Later in life the hope of permanent relief is remote and one's attention must of necessity be directed toward alleviation rather than cure.

The treatment may be divided for our purposes into three stages—prophylactic of the attack itself, and between attacks. The first includes good, wholesome food, plenty of fresh air, proper bathing and exercising, care of the bowels, and prompt attention to any abnormal condition that may develop, especial attention being paid of course to the nose and throat.

The treatment of the attack itself is purely medicinal and should consist of the most rapid known means of relief. Unfortunately all patients do not respond to the same line of treatment and valuable time is frequently wasted hunting for a remedy for the case at hand. In the physician's hands nothing works with anything like the magic charm of morphine hypodermically and nitrite of amyl by inhalation. These may either be used in conjunction or separately, but if morphine is to be relied upon always remember to give enough and not putter around with minimal dosage. Chloroform is frequently recommended and does well for the moment but often we are disgusted to see the wheezing start again as soon as the effects of the drug begin to wear off. Adrenalin chloride solution too is used by many physicians and apparently with excellent results in some cases, but I have never had any success at all the few times I have tried it and prefer the other and surer remedies. If exhaustion is extreme or collapse threatened, a cup of strong coffee will often fill the bill admirably, but one should not hesitate to use strychnine, caffeine, camphor, or any other stimulant he may have at hand if he thinks it needed. Mild attacks are frequently relieved or, if taken in time, aborted by the use of various fumes among which belladonna and stramonium probably rank first. The most convenient method of administration is in the form of cigarettes of which there are several well known brands on the market.

Treatment between attacks is climatic, hygienic, and medicinal, and should always be insisted upon by the conscientious physician. It is a well-known fact that diametrically opposite climatic conditions to those under which the patient lives will oftener than not cure a case of asthma, at least for the time being. With this idea in view it is well to investigate carefully the surroundings and then suggest a number of possibilities, always impressing upon the sufferer that he must keep going until he strikes the right place. Strangely enough small, smoky cities, the smokier the better, seem to be the places where most asthmatics eventually turn up. Many of us would suffer the torments of the damned breathing in the awful mixture that they seem to thrive on. The condition of the body is of paramount importance to these people and one must impress upon them the necessity of daily bathing, care in the selection of the food, proper mode of dress, daily evacuation of the bowels, and above all plenty of outdoor air. Breathing exercises combined with gymnastics have been recommended and many physicians strongly advise their patients to take a course of carbonated brine, or Nauheim baths, as they are called. This is not such bad advice either and often works wonders, particularly when the right heart has begun to dilate under the excessive strain.

Of the drugs, according to Goodhart and Spriggs in Allbutt and Rolleston's "System of Medicine," there is nothing to compare with arsenic in the form of Fowler's solution given three times a day in small dosage for periods of three or four weeks with intermissions of equal length. Next to this a combination of strychnine and the iodides appears to be the favorite prescription and perhaps is more generally used than the other although there are not such enthusiastic claims made for it. Phosphorus and the bromides have their supporters and undoubtedly do good in selected cases. Among so-called specifics pollantin may be mentioned and in at least one case of hay-fever that I recall it seemed to work wonders, but I have known it to fail often where results were most confidently expected. One other line of treatment perhaps should be considered here which offers a possibility of results far and away beyond anything else I know of. I refer to autotherapy as elaborated by Duncan of New York. I will not attempt to describe this most interesting process but will simply refer to his articles in the MEDICAL RECORD and the *New York Medical Journal.*

**Cholecystitis and Cholelithiasis in Childhood.**—A. v. Shautz notes the extreme rarity of these conditions in early life. Only fifteen cases of gallstones occurring in children have been reported in the literature. The clinical picture is the same as that observed in adults. Pure cholecystitis without stones is still less common.—*Centralblat für die Grenzgebiete der Medizin und Chirurgie.*

# SCIENTIFIC SANITATION IN RURAL HEALTH WORK.

By HARVEY B. BASHORE,

WEST FAIRVIEW, PA.

COUNTY MEDICAL INSPECTOR, DEPARTMENT OF HEALTH, WEST FAIRVIEW, PA.

It is very evident, not only to those engaged in public health work, but to every physician, that sanitary science is going through a transition stage, and that the more we are finding out about the real cause of disease, the more are old methods of fighting it disappearing. Already we are far ahead theoretically in this matter and know just exactly how to limit the spread of a number of diseases, but to practice effectually what we know in theory, we need the assistance and co-operation of an enlightened public, yet it seems hard, very hard for the public to give up their ancient ideas. I recall a case which well illustrates this: Some years ago I was talking on typhoid fever at a farmers' convention, under the auspices of the Department of Agriculture, and I had taken great pains to tell the audience that human discharges are the only real dangerous thing in the transmission of this disease, and that if these infected discharges were kept out of drinking water and food, there would be very little typhoid fever. After I had finished one old gentleman got up and said he had enjoyed my talk very much and wanted to add a word. He said that he knew a family where they had sickness of some sort nearly all the time; their neighbors became alarmed for them and finally prevailed upon them to clean out the old well; and what do you think they found? Two dead frogs and a dead snake. "Now, is it any wonder," the old gentleman said, "that they had sickness? We cannot be too careful of the drinking water." So my endeavors had fallen flat, very flat indeed.

Garbage, sewer gas, filthy gutters, and ponds are all accused by the public of causing untold woes and sickness, but, of course, have really nothing to do directly with causing disease, and very little indirectly. In rural work we have great trouble with the pig-pen nuisance, and I have heard the pig-pen accused of causing almost every disease we have. Of course, pig-pens are a nuisance, especially in thickly settled communities, but it is just as well to remember that they do not cause any disease whatsoever. Here is a little story somewhat on this point: One of our health officers, a layman, of whom I had previously inquired the probable cause of a house epidemic of typhoid fever, meeting me some time after, said very solemnly: "Doctor, I have at last found the cause of that typhoid fever. They keep a swill barrel in the cellar."

One case of measles or diphtheria in a school, especially among those who doctor themselves, is of vastly more importance to the public health than a damp, dirty cellar or an overflowing privy, but it is very hard to make the public believe this. It is, nevertheless, beginning to be pretty broadly accepted that the spread of the common contagious diseases is brought about by the "carrier" and the neglected mild case. If we could only get hold of these, sanitary work would become very simple and effective. In the country districts the mild case which has no doctor causes most of the trouble. In the city, during nine months in the year at least, daily school inspection has done much to eliminate these "missed" cases, but in the country school system such supervision is impossible at present. In Pennsylvania, however, under Dr. Dixon's wise guidance, we are trying to overcome this sanitary loophole by educating the teacher and the parents, supplemented by special school inspections when necessary: educating the teachers to be on the watch and to send home every child apparently sick, and to notify the proper authorities if suspicious of a contagious affection; then in addition, educating the parents to consult a physician for even minor ailments, especially when symptoms point to any of the contagious and infectious diseases; very often, by measures like these, in fairly intelligent communities, it is very easy to keep down epidemics. I recall an instance in which a case of diphtheria appeared in a certain country school, and the teacher reported that some other children had "sore throats." So we promptly examined the throats of all these children and sent three home, who had slight fever and inflammation of the fauces; two of the three developed diphtheria in a few days, but they were at home, isolated and not spreading contagion among the rest of the children. It is needless to say we had no epidemic. I recall another instance in which this emergency inspection did much good. In a certain town of 5,000 inhabitants there was a number of cases of a slight eruptive disease, called "frizles" by some of the local doctors. Finally the local health board asked help from the State Department of Health. We immediately went through the schools and examined about 300 children. We found a number who were just about recovering from a mild attack of scarlet fever, and we found two cases of the fully developed disease. All these cases were quarantined, the schools disinfected, and the epidemic of "frizles" vanished.

In the matter of limiting the spread of disease by milk, considerable progress is being made by restricting the sale unless proper precautionary measures are used, such as will surely keep the pathogenic germs out of the milk, but right here our work is imperfect on account of the "missed" case. Here is an actual instance of which I am sorry to say, there are some duplicates: A man who was conducting a small dairy farm became sick. He didn't consult a doctor, but kept at work. Finally a number of people using his milk developed typhoid fever and when an investigation was made the dairyman himself was found to have had this disease in a mild form. As his case had not been reported to the health authorities, no restrictions were placed on the sale of his milk, and as a result thirty-four people developed the disease and several died. Cases like this emphasize the fact that we cannot have effective health administration, except by the aid of an intelligent public educated in the means of the transmission of diseases and educated to consult a physician for lesser ailments, or at least to so conduct themselves as not to transmit a possibly contagious affection.

A great deal of our rural typhoid fever, by the way, is due to "contact" on account of less attention to, and lack of facilities for, personal cleanliness, which exist in city houses of the better class. I have one record of thirty-five cases occurring in six houses: there should have been only six cases at the most, but carelessness and neglect of the simple ordinary rules of cleanliness made the others. I recall a bad house-epidemic of this disease in a certain locality last year where there were fifteen cases in two houses—all developing one after another by "contact" from one or perhaps two primary cases. The environment was so bad that I took a State

health officer and a nurse and instituted a general cleaning up. For although it is questionable if typhoid fever germs will live long in filth, the habits which permit filth to accumulate account for much of our rural typhoid fever. For a long time that day I missed the health officer and finally found that he had been tramping all over the farm hunting something to account for the typhoid fever, and had he found a dead cat or a sick dog, I feel sure he would have come to me with glee. And then right there I saw the old and new hygiene—the health officer hunting a dead cat or a sick dog as the cause of the illness; that was the old method, reaching far back to the Middle Ages. And the nurse in the kitchen showing the attendants how to keep the hands clean and how to disinfect the discharges of the sick; that was the new method, the sanitation of to-day and to-morrow.

While we want to get rid of filth more than ever, on account of its being a nuisance, a breeder of flies, and a breeder of bad habits, the day of the dead cat, the sick dog and the swill-barrel as causes of disease is fast passing away, and in a few more years we will wonder why we were ever so stupid or so antiquated.

## A CASE OF TRICHINOSIS WTH AUTOPSY.*

By E. P. BERNSTEIN, M.D.,
NEW YORK.

In reviewing the literature of this disease for the past few years, we are impressed with the fact that either the condition is much more common than formerly or our diagnostic aids have made its recognition so much easier that there is an apparent increase in the number of infections by the *Trichina spiralis*. Probably both factors play a role in increasing the number of cases reported. We have but to remember that the foreign element of our population is constantly increasing—prominent among whom are the Italians and Austrians—both heavy consumers of raw or smoked ham. We must also not forget that beef, geese, dogs, and rabbits have been the means of infection in man. Furthermore, the recognition of this disease has become more easy through increased and more refined laboratory methods.

From a clinical point of view the symptom complex is well established, but the pathology of the disease is still somewhat unsettled—especially that branch dealing with the mode of passage of the embryos from the intestinal tract to the muscles.

Several facts which have been well established but are too often lost sight of, should be emphasized, for they easily explain why the stools have never contained the trichinæ, and also why the parasite should not be expected in the blood at all times.

Staubli has proved that the adult trichinæ cannot produce the disease. It is conveyed from host to host only through the embryos. This fact has too often been forgotten. He showed that if rats developed an acute intestinal trichinosis after eating flesh containing a great number of embryos, and this condition became severe enough to cause the rat's rapid death, then this animal was no longer a factor in the propagation of the disease, for if its body musculature and organs are in their turn eaten, they do not cause the disease, the rat not having had time to develop muscle embryos. These latter are the infecting agents.

Taken in food, the surrounding membrane of the embryo is dissolved by the gastric juice, and the parasite is now free to attach itself to the mucous membrane of the intestinal canal. Here copulation takes place at the earliest in from six to eight days, the embryo being transported through the lymph spaces to the blood vessels and finally to the muscles. The embryos are present in the circulating blood for about three weeks. Since they are never discharged into the lumen of the intestine, it is not to be wondered at that no author has as yet succeeded in finding them in the stool. And yet, how often is a specimen sent to a laboratory with the request that it be examined for trichina embryos! The uselessness of the procedure is apparent.

Also, since the embryos are in the circulation for but three weeks at most, we should not be surprised at our failure to find the parasite in the blood in long standing cases—and yet in just such cases we are often called upon to employ the technique of Herrick and Janeway for their detection.

The absence of embryos in the blood in the case under consideration was proved not only by the failure to find them after a careful and prolonged search in the hemolyzed, centrifugalized blood, but also by feeding the sediment from ten cubic centimeters of fresh, defibrinated blood to guinea pigs who remained healthy for four weeks and were then killed and found entirely free from the disease. The above result was to be expected, since the case was fairly advanced when admitted to the hospital.

The case is of interest as it shows the wide distribution of the embryos in all of the voluntary muscles, and their absence in the involuntary muscles of the heart and intestines.

The patient, an Italian, was admitted to the Lebanon Hospital on the medical service of Dr. A. Mayer. His present history dates back some ten days, when he had several severe chills followed by a rise in temperature, generalized pains, vomiting, and diarrhea. His physical examination on admission showed nothing pathological except in his musculature—his forearms were flexed on his arm, and it was impossible to extend them passively or actively—attempts to do so causing excruciating pain. His mouth could be opened for only about one-half an inch, while he was unable to protrude his tongue beyond the line of his teeth. Pressure over any of the muscles of the extremities, chest, or head caused severe pains. His temperature ranged between 100° and 104°, with a pulse rate of 100 to 112.

Urine analysis constantly gave a strongly positive diazo reaction. This test is too often neglected in the diagnosis of trichinosis, and yet it is a very valuable help, being almost always positive. Examination of feces for ova was negative.

Blood examination showed a leucocytosis averaging about 17,800, with an eosinophilia of 7½ per cent. Blood culture was sterile. A careful search for ova in the blood was negative, while animal experimentation in the attempt to convey the disease from the patient's blood to guinea-pigs through feeding was also without result. Since these examinations were performed long after the embryos had left the circulation, the failure to find or convey them is not to be wondered at. A section of the left gastrocnemius muscle, teased in normal saline solution, showed numerous motile specimens of *Trichina spiralis*.

*From the Pathological Laboratory of Lebanon Hospital.

The patient died after sixteen days in the hospital, and the post-mortem examination was performed four hours after death. It revealed no gross pathological lesions in any of the organs.

Microscopically, the trichinæ were found in all of the voluntary muscles, including the intercostals, psoas, sternocleidomastoid, and diaphragm. They were, however, most numerous in the musculature of the tip and base of the tongue. As mentioned before, the intestinal and heart muscles were negative, as were also the liver, kidneys, suprarenals, spleen, lungs, and pancreas.

In conclusion I would again emphasize the following facts:

1. Examine the urine for the presence of a diazo reaction.

2. Do not expect to find ova in the stools of an established trichinosis case.

3. The parasites are in the circulation for but three weeks at most.

4. The ova are deposited in the voluntary muscles only.

64 West Eighty-third Street.

## REPORT OF A CASE OF COMPLETE TRANSPOSITION OF THE VISCERA.*

By S. HORWITT, M.D.,

NEW YORK.

"According to Vierordt, a case of undoubted dextrocardia has not yet been observed—or at any rate has not yet been confirmed by an autopsy" (Birnbaum). The cases where the heart was found intravitam by physical examination to lie on the right side were mostly acquired conditions due to pathological processes in the neighboring viscera. Left pyo- or pneumothorax will push the heart over to the right side of the sternum and pathological contractions in the right chest will pull the heart to this side. By dextrocardia proper is understood a congenital malformation. It is usually a part of the condition known as situs inversus, where all the viscera, thoracic, and abdominal are placed on the wrong side of the body.

Cases of situs inversus arouse our interest on account of their rarity alone. Then there are possibilities of the condition acquiring more importance than that of merely being a freak of nature. For instance, an attack of cholecystitis or of appendicitis in such a subject would probably for a time puzzle the surgeon who relegates the use of the stethoscope to his medical confrère.

In the cases of complete situs inversus, to which our case belongs, the disposition of the viscera, both thoracic and abdominal, is "a looking-glass image" of the normal or usual condition. It is obvious, therefore, that this abnormal condition presents no handicap to the proper physiological functioning of any of the organs. In fact, this unusual state of affairs is ordinarily found accidentally in patients who present themselves to us for ailments common to normal individuals.

The case we are to report, for instance, came to the hospital for pneumonia. Following is the history:

W. D., colored, twenty-six years of age, entered the Lebanon Hospital on February 9, 1913, on the service of Dr. R. Stein. Family history, irrelevant. Previous history, never been ill before. Present history. About four days before admission patient was seized with a chill lasting about half an hour, followed by fever, cough, and pain in the back of his chest. Bloody expectoration appeared. Appetite poor, bowels constipated.

Physical examination on admission showed the general condition fair; patient well nourished and developed; dyspneic.

Chest.—Left side, posteriorly, dulness, bronchial breathing, bronchophony, many moist râles over this area; a few moist râles at the right base.

Heart.—Right border, 3½ inches to right of sternum; upper border, third space on right side; left border, at left border of sternum. Apex beat in fifth right intercostal space, 3½ inches to the right of the median line. First sound of poor quality, accompanied by a systolic murmur which is transmitted to the right. Reduplication of first sound and accentuation of the second pulmonic. Pulse regular; no sclerosis of vessels.

Liver, dulness begins at fifth space on left side, flatness ending at free costal border. Spleen, percussed on right side, not palpable.

While in the hospital the patient ran an average pneumonic course. On the sixth day the fever commenced to decline by lysis. On the seventh day he developed edema of the cervical tissues, and on the ninth day he died, with dyspnea as the dominant symptom.

*Autopsy* February 12, 1913.—Fairly well nourished man. Scalp, skull, meninges, and brain, negative. Neck looks brawny. Cut surface exudes a clear serous fluid with which the areolar tissues are infiltrated. The parts involved include the anterior and lateral aspects of the neck, and also the floor of the mouth. There was no edema of the glottis or of the epiglottis.

Chest.—Left lung (corresponding to normal right) showed a middle lobe which was but imperfectly marked off by a vestigial fissure from the upper lobe. Right lung (corresponding to normal left) presented two lobes. Left lung showed consolidation of the upper and greater part of the lower lobes.

Heart.—Pericardial sac appeared as a "looking-glass image" of the usual disposition and relationships. The vena cava superior was seen to lie to the right of the aortic arch. The aortic arch curved from left to right. The pulmonary artery lay at the right of the ascending portion of the arch, while its *left* branch coursed to the left and behind it. The innominate artery sprang from the arch, to the *left* of the trachea, while on the right side the subclavian and common carotid arteries arose from it. The remainder of the arteries and veins followed the same reversed arrangement.

Abdomen.—Here again the distribution of the viscera might be best depicted by picturing to oneself the looking-glass image of the usual distribution. The liver lay in the left hypochondriac and epigastric regions, the spleen in the right hypochondrium. The stomach was in the right hypochondriac and epigastric regions, the pylorus being to the left of the middle line. The duodenum lay with its convexity pointed to the left, and situated to the left of the vertebral column, while its concavity embraced the head of the pancreas, which organ passed over to the right. The ileum opened into the large intestines in the left iliac region, where also the appendix was situated. The course of the large intestine was reversed, the sigmoid flexure appearing on the right side, where it dipped over the pelvic rim to end in the rectum.

The explanation of this anomaly? Let us again quote from Birnbaum: "There are two possible explanations of these cases: (*a*) some condition inherent in the fertilized ovum and producing its results when the ovum is undergoing division into its two primitive blastomeres; or (*b*) some cause acting upon the ovum from without—in the great majority of cases still at the very early stage of its development. The exact nature of the cause is unknown."

Lebanon Hospital.

*From the Pathological Laboratory of Lebanon Hospital

**The Pigmentary Cirrhoses.**—G. Roque, J. Chalier, and L. Nové-Josserand conclude from their investigations that the pigmentary cirrhoses should not be considered apart from other pathological conditions associated with a ferruginous pigmentation of the organs of the body. In spite of the opinions of former authorities, the pigmentary cirrhoses have no special individuality, the iron pigment deposited in the liver being the result of an hemolysis.—*Revue de Médecine.*

## NEGATIVE EUGENICS.

THE science of eugenics has barely been launched and yet even its most enthusiastic exponents are beginning to realize that practical results can come, if at all, only through the practice of its negative phase. It is obvious that, as much as it might be desired on scientific grounds, the methods of the stock-farm are inapplicable to human beings. But the study of heredity has established almost beyond any doubt that in man certain diseases, but more particularly defects, are transmitted from ancestor to progeny. This makes it of far more importance to prevent that transmission than to attempt to build up synthetically a finer but idealistic product.

Recent investigations in certain parts of New Jersey have disclosed the existence of veritable colonies of defectives, so that the famous Jukes family promises now to be duplicated many times over. Many States, having been persuaded of the hereditary character of defective constitutions and defects, have passed statutes permitting and providing for the sterilization, under certain conditions and safeguards, of the defective and the criminal inhabitants of public institutions—the latter on the principle that most criminals are defectives—in the hope that thus will the propagation of these "species" be prevented. The legality of this procedure has been attacked. In the defectives it is defended under the "police power" of the State as a measure enacted "to protect the health, welfare, safety, and even convenience of the public." In criminals it is opposed on the ground that it is "cruel and unusual punishment," and therefore against the constitutional restriction of the eighth amendment to the United States Constitution. The legal phase of this question is, however, still open, and must be finally passed upon before this practice can have universal application.

On the other hand, some very prominent scientists have expressed themselves as opposed to this practice on the ground that an individual himself defective, and perhaps born of the union of a normal and a defective parent, either immediate or ancestral in degree, may yet produce normal offspring, because, on the Mendelian doctrine, though the individual is himself defective or "recessive," he may have within him the dominant determiners of his normal ancestry, which alone may be transmitted under certain conditions yet little understood. In this manner, the defective or "recessive" characteristic in, and causing, hemophilia is transmitted only through the female offspring; and if there is no female offspring the condition necessary for the transmission of this constitution is not present, and is thus wiped out. Conversely, two normal individuals may have dormant within one of them at least, an ancestral "recessive" characteristic, which their union may transmit to one of their offspring in a patent form. This explains the reason for the birth of one defective in an otherwise normal and even highly developed family. And the opponents of sterilization contend that until something more is learned of the *method* of the hereditary transmission of defectives, sterilization as a public welfare procedure is not justified and is unscientific. Sterilization should therefore be carried out only with the view in mind of the possibility of sacrificing thereby the lives-to-be of normal individuals in the endeavor to prevent the inception of the lives-to-be of defective ones—if, indeed, future lives have a value. This form of negative eugenics is, however, limited in scope, and applicable only to the inmates of public institutions.

The form that is intended to affect the public more generally is the proposed requirement of those contemplating marriage to submit certificates of good health as conditions precedent to the issuance of license to marry. If this is universally carried out, it will throw another burden on the shoulders of the physician, whether he will be acting in his private capacity or as a public official delegated to make examinations. He will be called upon to pass upon a very vital matter in the organization of society. And further, his certificates will be deemed policies of insurance, so to speak, not only insuring against the existence of present patent or latent diseases or defects in the contracting parties, but also subsequent ones arising even from other causes. In so far as venereal diseases are concerned—against which the largest part of this propaganda is aimed—it may be comparatively simple, especially when the diseases are in the acute or subacute stages. But how many latent cases of gonorrhea escape detection, even after the most painstaking and scientific methods of examination, and in individuals who will not marry unless they are free from disease? Even recently active syphilis can be made to escape detection by the Wassermann reaction after a little antisyphilitic treatment, not to mention the many instances in which the reaction is negative in clinically positive cases not under treatment. Nor can incipient cases of tuberculosis always be recognized. Positive cases of insanity will escape the examiner if brought to him during a period of remission, or, in the paranoid types of insanity, when the delusion is not apparent or is purposely concealed. Again, in the case of epileptics, a sufficiently positive diagnosis can never be made if they are seen between the attacks, except when there is marked physical or mental deterioration from the frequency of seizures. But how can this requirement ever affect, even on the most liberal and the broadest construction, the individuals

who are themselves admittedly fit, but are "tainted" in their immediate or remote ancestry? To forbid them marriage would not be reasonable. In every case, however, where defect or disease would manifest itself after marriage, either in the individuals themselves or in their offspring, the physician would be under the gravest suspicion, and the integrity and competence of the whole profession would be attacked—at least by that portion of the public that seems ever-ready to hear the worst of medical science.

These factors must, therefore, be taken into consideration by physicians before they endorse unreservedly the dictum compelling all persons to subject themselves to a medical examination as the *sine qua non* of marriage.

## THE TREATMENT OF INTESTINAL STASIS WITH LIQUID PETROLEUM.

An extremely interesting discussion which had been in progress for several weeks before the Royal Society of Medicine ended on May 7, 1913. The discussion came about through the desire of the physicians and surgeons of London to thresh out Mr. Arbuthnot Lane's views as to the causation of that aggravated form of disordered digestion known as intestinal stasis. Lane's views are fairly well known in this country. Herz, Keith, and others contended at the discussion that these effects are not due to kinking but to a derangement of the ileocecal sphincteric mechanism. The arguments on both sides were plausible, but the matter was left in *statu quo*. A feature of the discussion was that several eminent authorities, including Lane, recommended the use of liquid petroleum in the treatment of this condition. In fact, Lane was the first, or one of the first, to draw attention to the value of this mode of treatment. Mr. George Rowell said that with regard to pyorrhea alveolaris, he would like to remark that he had seen complete cures by vaccines as well as by scrupulous local treatment, and that he knew of many cases in which the cure had been much aided by paraffin internally. Two of his dental friends of large experience made an almost routine practice of prescribing paraffin for these cases. Rowell went on to say that a large number of facts were being brought to light in various branches of medical knowledge which, when examined, were found to fit in with and to lend support to Mr. Lane's theories. The question of infant feeding might be alluded to as an example. In 1901 Dr. Eric Pritchard came to the conclusion that disease in infants, and much disease in after life, was largely due to overfeeding during the first year. This he held caused overdevelopment in the length of the bowel, such overgrowth often extending to many feet; there was no adequate room for the bowel, peristalsis was impeded, and delay in the passage of the contents of the intestine resulted. For the prevention and treatment of the condition he had given paraffin very largely, and, agreeing with Mr. Lane, was convinced that the constant exhibition of paraffin had a marked effect in both the prevention and the cure of tuberculosis. The testimony of Alfred C. Jordan, the medical radiographer at Guy's Hospital, was even more favorable as to the efficacy of liquid paraffin in the treatment of intestinal stasis, while Murray Leslie and Ernest Clarke were enthusiastic as to the benefits obtained by giving persons suffering from intestinal stasis considerable amounts of liquid paraffin. Eric Pritchard and G. A. Sutherland strongly recommended its use in the obstinate constipation of infants and children. In his book entitled "The Physiological Feeding of Infants," Pritchard says: "There is no vegetable or animal oil that can reach the lower bowel and soften constipated stools unless it is given in such excess that it is neither digested nor absorbed; hence there is danger of fat dyspepsia; but a mineral oil such as petroleum, in whatever doses it is administered, will always reappear in the motions and soften them to an extent which is directly proportional to the amount given. Petroleum cannot decompose in the bowel and cause offensive motions like excess of fat. It cannot become absorbed and tax the resources of the liver; in fact, it behaves as the most perfect mechanical lubricant of the bowel and as far as I know has absolutely no injurious therapeutic action." If further experience confirms the findings of Lane, Pritchard, Leslie, and others there should be a large field for the employment of liquid paraffin in therapeutics.

## MILITARY SURGERY IN THE TIME OF THE GREAT NAPOLEON.

Perhaps one of the most unique and interesting books of its kind ever written is the "Memoirs of Military Surgery," by Baron Larrey, the distinguished army surgeon, who served under Napoleon Bonaparte. The latter had the faculty of attracting to his service remarkable men, or possibly he had the genius for detecting and bringing out talent. Not only was Larrey a brilliant surgeon but he was also greatly in advance of his time. As is pointed out by J. C. Da Costa in a paper contributed to the *U. S. Naval Medical Bulletin* for April, 1913, he advocated certain operative procedures which have since been universally adopted. Primary amputation was opposed by military surgeons in those days, but Larrey preferred it to secondary amputation, and undoubtedly saved a large number of lives which would have been lost by delay. He devised a method of disarticulation of the shoulder joint. This method still bears his name and has not been improved on. He disarticulated at the hip joint, tying the artery first. His first operation of this nature was in 1798, and was the first case on record in the annals of military surgery. Larrey in his memoirs states that his views as to the value of early amputation found practical confirmation in the experiences of surgeons during the American Revolution. In that war the French surgeons would not amputate early and the mortality among the French soldiers was very large; but the American surgeons performed primary amputations, and the mortality among the Americans was very small, which seems to show that at that early date American surgeons were independent and progressive.

Larrey advised and practised excision in suitable cases, although the operation was not performed extensively until Syme of Edinburgh and Ferguson of London rendered it popular, thus vindicating the views of Larrey.

The French surgeon was strongly opposed to meddlesome surgery and was accustomed to change dressings only when such change was absolutely necessary. In gunshot wounds of the chest he excised a portion of a rib and incised the pleural sac. He found that the making of such an opening was followed by the cessation of bleeding and if pus subsequently formed a drainage opening was ready to allow of its exit. Larrey did not know how the opening stopped the hemorrhage, he only knew that it did so. Da Costa points out that the hemothorax which occurs presses on the lung and arrests the hemorrhage and states that he has practised this method several times with success.

In fact, there is little doubt that Larrey contributed a good deal to modern military surgery and few will take exception to the statement that he was one of the greatest military surgeons that ever lived.

### The Use of Snuff and Tobacco by School Children.

While pursuing certain studies on hookworm disease in one of our South Atlantic States, the fact was elicited by officers of the Public Health Service that there was a considerable amount of snuff dipping and tobacco smoking and chewing by boys and girls in schools of a section of the State. Drs. Charles Wardell Stiles and S. W. Altman have made this the subject of a public health report. The children varied in age from eight to eighteen years and the data obtained were interesting from both the medical and social points of view. The answers obtained were tabulated in reference to the presence or absence of a privy at the house or farm at which they lived on the assumption that better sanitation and increased refinement would probably go hand in hand. Of 69 boys for whom data were available, 18, or 26 per cent., admitted the use of tobacco, and half of these children lived in houses provided with privies, while the other half lived in homes not so provided. Of 7 who dipped, 2 lived at homes with privies and 5 without. Of the 59 girls for whom data were available, 13, or 22 per cent., admitted the use of tobacco, and of these only 2 lived in homes provided with privies. Of the 10 girls who dipped snuff, 1 lived in a home with, and the others without a privy. All 8 girls who chewed lived in homes without privies. That such a deplorable condition should exist among the young of any portion of the country is hard to believe, but according to Stiles and Altman, these dirty habits are due to the manner in which children are brought up. They are merely the creatures of their environment and until education exerts its influence this state of affairs will continue. Moreover, the authors state that in some instances children are advised to use tobacco and snuff by physicians as a preventative of anemia, generally owing to hookworm disease. It has been thus a case of the blind leading the blind, but, of course, the ignorant physician is rapidly passing away and when he has wholly gone and education holds sway, a new era of enlightenment and sanitation will dawn.

### Voice Restored by Paraffin Injection.

In theory there is hardly any limitation of the use of paraffin prothesis to make good losses of tissue. Time, however, is required to determine whether this resource is practicable—whether indeed it is not harmful. At a recent meeting of the Munich Aerztlicher Verein (*Münchener medizinische Wochenschrift,* June 3) Kretschmann exhibited a patient who about one year before had received an injection of paraffin in a paralyzed vocal cord band. The voice was at first rough and without much resonance, but now it has become natural. The position of the cord is also natural to a certain extent; but when the cords touch in phonation the arytenoid cartilage of the paralyzed side is seen to undergo peculiar movements. These must be due to the action of the cricothyroid muscle, which is innervated by the superior laryngeal nerve, while the paralyzed cord is innervated by the recurrens.

### "Dichotomy" in Germany.

Dichotomy in the sense of fee splitting is a subject which has of late been much discussed in Germany. In the news column of the *Münchener medizinische Wochenschrift,* June 3, it is recorded that while the two leading medical societies of Munich condemn the practice, there are differences of opinion as to what dichotomy really means. One society holds that reciprocity in referring cases may readily lead to fee splitting. The same body says "let the man who refers a case to another, send an account for his services." The other society would limit the fee of the referring practitioner to no more than he would be naturally entitled to by his fee table. As the difference of opinion is immaterial both societies will adopt a uniform code.

## News of the Week.

**City Death Rate.**—During the week ending June 14, there occurred in New York City a total of 1,303 deaths, giving a death rate of 12.65 per thousand of population, as compared to 1,204 deaths and a rate of 12.14 for the same week of last year. The increase extended throughout all of the age periods, though it was less in the earlier ones, and was noted in practically all of the chief causes of death, including measles, diphtheria, croup, whooping cough, and bronchial pneumonia especially. As compared to the preceding week of this year, however, there occurred a reduction of thirty-five in the number of deaths of infants under one year of age.

**State Statistics.**—During the month of April, 1913, there were registered in New York State 12,414 deaths and 18,013 births. Of the deaths 1,561 were due to pulmonary tuberculosis and 6,561 to cancer.

**Moving Pictures.**—The New York Department of Health, assisted by the Committee on the Prevention of Tuberculosis on June 16 gave in Mount Morris Park, New York, the first of a series of moving picture shows illustrating the best methods for the prevention and cure of tuberculosis. The shows will be given throughout the summer in the parks and on the recreation piers. It is estimated that last season the pictures were viewed by more than 100,000 persons.

**American Medical Editors Association.**—At the annual meeting of this Association, held in

Minneapolis, June 16, 1913, the following officers were elected: *President,* Dr. E. A. Van der Veer, Albany, N. Y.; *First Vice-President,* Dr. H. Edwin Lewis, New York; *Second Vice-President,* Dr. Seale Harris, Mobile, Ala.; *Secretary and Treasurer,* Dr. Joseph MacDonald, Jr., New York; *Executive Committee,* Drs. C. F. Taylor, Philadelphia, Pa.; D. O. English, New Brunswick, N. J.; W. C. Abbott, Chicago, Ill. *Publication Committee,* Drs. H. Edwin Lewis, New York, Chairman; Charles Wood Fassett, St. Joe, Mo.; A. S. Burdick, Chicago, Ill.; James P. Warbasse, Brooklyn, N. Y., and J. MacDonald, Jr., New York, Secretary.

**The Montana State Board of Medical Examiners** will hold a special meeting on Tuesday, July 8, at Helena, to examine candidates for a license to practice in that State.

**Honorary Degrees.**—Dr. Edward Tyson Reichert, professor of physiology in the medical department of the University of Pennsylvania, received the honorary degree of Doctor of Science from the University at the 157th annual commencement on June 18.

Dr. Harvey Cushing, professor of surgery in the Harvard Medical School, received the honorary degree of Master of Arts from Yale University on June 18.

Dr. Wickliffe Rose of Atlanta, Ga., at the annual commencement exercises of Harvard University on June 19 received the degree of Master of Arts, as did also Dr. Walter Elmer Fernald of Boston.

**Dr. Friedmann Sails.**—Asserting his continued belief in the efficacy of his serum and in the eventual acknowledgment of his claims, Dr. Friedrich F. Friedmann sailed from New York for Germany on June 17. To newspaper reporters he stated that he regretted that he had fallen into "bad hands" upon his arrival in this country, and in echoing this regret the medical profession and the laity for the first time find themselves in accord with him.

**Plague in Hayti.**—An epidemic of bubonic plague has been reported from Jacmel, a seaport thirty miles from Port-au-Prince, Hayti. A number of deaths have occurred. The Cuban Government has ordered several gunboats to patrol constantly along the coast of Oriente Province in order to prevent the landing of immigrants from Hayti and their entrance into Cuba without first passing the health authorities.

**Cancer Bequest Contested.**—Notice of the contest of the will of the late Henry E. Rutherford, who left a legacy of $200,000 to the Rockefeller Institute for research in cancer, has been filed.

**Personals.**—Dr. Simon Baruch was one of the speakers at a dinner given by the Saratoga Springs Medical Society on June 17 to the members of the New York State Mineral Springs Reservation Commission.

Dr. William J. Mayo of Rochester, Minn., has been elected a foreign corespondent of the Paris Academy of Medicine.

**Meat Under Pure Food Law.**—What is described as probably the most far-reaching and radical extension of the Food and Drugs Act went into effect on June 16 by unanimous vote of the Secretaries of Agriculture, the Treasury and Commerce. This consisted in the placing of domestic meat and meat food products for the first time fully under the provisions of the Food and Drugs Act, so that manufacturers of meat foods will henceforth be required to comply with this act as well as with the Meat Inspection Law.

**International Medical Congress.**—On June 21 the number of Americans registered as delegates to the International Medical Congress in London, from August 6 to 13, had reached 840, and it was expected that the attendance of physicians from this country would be at least 900.

**Sir Jonathan Hutchinson** of London died on Monday of this week in the 85th year of his age. He was a surgeon of great repute and equally eminent in ophthalmology and dermatology, and was also an acute observer and a great teacher. His name appears frequently in eponymic terminology, the best known term being "Hutchinson's teeth," indication of hereditary syphilis. Some years ago he advanced the hypothesis that leprosy was caused by the eating of stale fish, and for a time the theory gained some acceptance by the mere weight of his authority. His contributions to medical literature were numerous, most of them, other than the articles in support of his lepra theory, being on syphilitic affection of the eyes and skin.

**Obituary Notes.**—Dr. F. R. Smalling of Wrightsville, Ark., a graduate of the Jefferson Medical College, Philadelphia, in 1870, died at his home on June 6, aged 63 years.

Dr. Ernest M. Ellaby of South Park, Ky., a graduate of the Hospital College of Medicine, Louisville, in 1904, and a member of the American Medical Association and of the Kentucky State and Jefferson County Medical Societies, died at his home after a long illness on June 3, aged 38 years.

Dr. George Warren Jones of Boston, Mass., a graduate of the Harvard Medical School, in 1872, and a member of the American Medical Association and the Massachusetts State and Suffolk County Medical Societies, died in the Massachusetts General Hospital, from cerebral hemorrhage, on June 5, aged 64 years.

Dr. Charles H. Holt of Grand Rapids, Mich., a graduate of the University of Pennsylvania, Department of Medicine, in 1882, died suddenly at his home on June 2, aged 59 years.

Dr. Thomas H. Barnes of Suffolk, Va., a graduate of the Medical College of Virginia, Richmond, died at his home on June 4, aged 82 years.

Dr. James Samuel W. Williams of Oakville, Ont., a graduate of Victoria University, Medical Department, Toronto, in 1867, died at his home on June 4, aged 72 years.

Dr. Charles Drennen, formerly of Birmingham, Ala., a graduate of the University of Alabama, Medical Department, Mobile, in 1872, died at his home in Orlando, Fla., on June 3, aged 72 years.

Dr. Daniel J. Scully of Colorado Springs, Col., formerly of Brooklyn, N. Y., a graduate of the College of Physicians and Surgeons, New York, in 1899, and a member of the American Medical Association and of the Colorado State and El Paso County Medical Societies, died at his home from pneumonia, after a short illness, on June 16, aged 38 years.

Dr. John Howard Morgan of Westerly, R. I., a graduate of the New York University Medical College in 1868, a member of the American Medical Association, and the Rhode Island State and Washington County Medical Societies, and president of the Westerly Medical Association, died at the home of his daughter in West Orange, N. J., from cerebral hemorrhage, on June 21, aged 68 years.

# Obituary.

## FRANK HARTLEY, M.D., LL.D.

NEW YORK.

Dr. Frank Hartley of New York, professor of clinical surgery in the College of Physicians, Columbia University, died at his home from disease of the kidneys, after several weeks' illness, on June 19, aged 57 years.

Dr. Hartley was graduated from Princeton University in 1877, and from the College of Physicians and Surgeons, New York, in 1880, and following this spent two years in study in Vienna and Leipsic. At the time of his death he was attending surgeon of the New York Hospital and consulting surgeon to the French, General Memorial, Italian, and Mack Hospitals, New York; St. Joseph's Hospital, Paterson, and the White Plains Hospital. He was also a member of the American Medical Association, the New York State and County Medical Societies, the New York Academy of Medicine, the Society of the Alumni of Bellevue Hospital, the American Urological Association, and the American Surgical Association. His surgical achievements were great, and he was the originator of a complete series of operations upon the skull and brain of which perhaps the most noted was his famous bisection of the ganglion of the fifth cranial nerve, which marked the first successful cure for facial neuralgia. In 1910 Dr. Hartley received from Princeton University the honorary degree of Doctor of Laws.

# Correspondence.

## ACIDS IN THE TREATMENT OF CANCER.

To the Editor of The Medical Record:

Sir:—Dr. Bristol's article of May 3 regarding the use of acids in the treatment of cancer suggests that one case may be of some interest. The patient who was suffering from cancer involving the mouth and neck of womb, came to me December 1, 1909. I applied the liquefied crystals of carbolic acid to the ulcerated surface every third or fourth day, healing it in three months. From the first I gave aromatic sulphuric acid internally, 8 drops in water every three hours. From time to time I was obliged to use opiates for the severe pain at night. On May 25, 1910, the internal use of sulphuric acid was discontinued, all pain and soreness having disappeared some time before. There has been no recurrence of symptoms of any kind and the patient is now in perfect health. Robert Mason, M. D.

Exeter, N. H.

## THE SKIN REACTION IN TYPHOID FEVER.

To the Editor of The Medical Record:

Sir:—Further experience during the past year with the skin reaction in typhoid fever reported by the writer in the Medical Record, December 30, 1911, has brought out the following points: It seems to be essential that "prophylactic" vaccine be used rather than that used in the treatment of typhoid fever, *per se*. The original strength of less than 5,000,000 bacilli per c.c. (1 in 20 dilution) has proved to be too strong. Of late this strength has given an excessive reaction in the control cases and a mild reaction in the typhoid fever cases. The present strength of solution used is less than 1,500,000 bacilli per c.c. (1 in 45 dilution).

Francis A. Prendergast, M. D.

Brooklyn, N. Y.

## OUR LONDON LETTER.

(From Our Regular Correspondent.)

KING'S BIRTHDAY HONORS—INDIAN MEDICAL SERVICE—CANCER RESEARCH AND RADIUM—GUY'S MEDICAL SCHOOL; ADDRESS BY MR. BALFOUR ON ENDOWMENT OF RESEARCH—MINER'S NYSTAGMUS—TUBERCULOSIS SCHEME AT THE COUNTY COUNCIL—BEAUTIFYING PATENT MEDICINES—OBITUARY.

London, June 6, 1913.

There was a distribution of honors on the King's birthday, in accordance with custom. The medical profession was not omitted. A baronetcy was given to Arbuthnot Lane, whose surgical position is well known to you, and who was the operator on the Duchess of Connaught, now happily convalescent. Major E. A. Worthington, the Duke's medical attendant in Canada, and who watched the Duchess throughout her illness, receives a knighthood. A number of other knighthoods, and appointments and promotions in the various orders are also conferred on members of the profession in civil practice and in the services.

A Royal Warrant, dated from the India office cancels that of King Edward of 1908, and the present King's of 1911, with reference to promotion and precedence in the Indian Medical Service, and provides new rules by which the Viceroy and Governor-General in council shall be governed in this matter. Time will show whether the changes will prove acceptable.

Cancer research is in favor just now. Only a fortnight ago I reported Mr. Tate's donation of £10,000 for this object. Now I have to add that Mr. Arthur James, as a memorial to his late brother William, is placing at the disposal of the Middlesex Hospital the income of £20,000 for the scientific investigation of the disease which is being carried on at that institution. So last week I reported the statement at the Middlesex about the cost of radium. Thereupon the *Daily Express* opened a subscription for providing a supply of the costly remedy to the hospitals of London. In response £10,500 has already been received and distributed among the London hospitals. The high commissioner for Scotland has given £1,000 to the Edinburgh Infirmary for the same purpose.

The new buildings of the Guy's School were opened on Tuesday by Mr. Balfour. Like each of the other ten schools, it is in want of funds. The cost of medical education has increased so rapidly with the recent advances that the new entries into the profession are falling off and in the public interests it is being widely urged that endowments in some form are becoming essential. As to these Guy's buildings for the school they are independent of the hospital, and receive none of its funds. They have been more or less in the construction stage for some sixteen years. The department of physiology having been opened in 1897, that of anatomy was extended and very largely reconstructed in 1904, and that in turn was followed the next year by the biological department and the Gordon Museum.

At the ceremony Viscount Goschen took the chair and welcomed Mr. Balfour as a governor of the hospital, a disciple of science, and a supporter of the new building scheme. Further as one who in 1898 addressed the students and their friends, declaring himself an ardent believer in the endowment of research. There had been two other historic incidents in this enterprise,

one when Mr. Gladstone, the hospital's senior governor, opened the students' college; the other when King Edward opened the department of physiology. Mr. Balfour said it was a pleasure to him fifteen years ago, as the chairman had reminded them, to urge in that hall the claims of research on all who desired our country to maintain its place in what was the greatest of all the professions. Since then a hundred thousand pounds had been spent on these buildings in constructions and reconstructions, but twice that amount would be wanted before they could do all that they should do in the interests of medicine now and in the future. The necessity of increased expenditure arose chiefly from the inherent progress of science, some branches of which fifty years ago had less practical connection with medicine than now. As the connection of collateral sciences with medicine became closer, so the apparatus required increased in cost. To the public a hospital seemed a place for relieving the sick and injured. That was too narrow a view; it should also be a training ground for the physicians and surgeons of the future. How was that to be accomplished? To carry out that work required three gifts which were not necessarily present in a single individual. First, a successful professor of the healing art must be endowed with not only all that medicine could teach but with ready intuition in connection with diagnosis. Secondly, there must be men who could explain, for doing and explaining were very different things. Then they wanted men who could investigate—men who could map out, not provinces of which we know nothing—any fool could do that—but the direction in which the next advance should be made, where nature might most easily be compelled to yield her secret. Genius was rare in all professions and the medical could not hope for a larger share than others. All that could be done was to give happily endowed individuals the opportunity of exercising for the common advantage the gifts that God had bestowed on them.

But, Mr. Balfour went on to confess, he doubted if our organization did not need improvement in that we could not ask such men to sacrifice all claims upon them for the sake of research. It was certain the hospitals had not fallen short in healing or investigating, but progress had been so great that it had become necessary to assist them by some form of endowment so as to enable them to get and keep men with a genius for research. Actual, if passing, suffering touched all hearts and appeals to relieve it found ready response. But the appeal he now urged had no such advantage. He was speaking for the future, and in favor of prolonged research about which the public knew nothing; but if people exercised their imagination they would see that scientific medical research touched them as much as the necessity of helping the man who had broken his leg. Let people with means exercise their imaginations, the speaker said, and they would then readily find the £200,000 for which he asked to turn to the best account the building they had provided for half that amount.

The increase of miner's nystagmus is a source of anxiety in many directions, and a lecture on the subject was given on Saturday at the exhibition of mining machinery now being held in the Agricultural Hall. The lecturer was Dr. T. Lister Llewellyn, who has studied the disease in various mines. His researches led him to discredit the notion so widely entertained that the cramped position of the miner in his work is the chief cause. It is true that the disease only showed itself after the introduction of the safety lamps, and Dr. Llewellyn believes it is because the lamp does not give sufficient light. In mines where this lamp is used the percentage of nystagmus cases is 7.5, whereas in those mines where the candle is the illuminant the percentage is only one. The conclusion seems obvious that every effort must be made to improve the illumination. The lecturer seemed to think improvements might be made in the lamp, for the day of oil lamps is past, but there is scope for electric lighting.

Sir Ralph Ashton, late president of Mining and Geological Institute of India, who occupied the chair, emphasized the value of Dr. Llewellyn's researches, and hoped they would lead to important improvements.

Much difference of opinion is being expressed as to the proposal of the health committee of the County Council in favor of a comprehensive scheme for the treatment of tuberculosis in London. The Council has not hitherto been an authority providing for this. But the asylums board has and possesses the administrative machinery necessary. Most people think that one board should suffice. The principal objection I have heard against the asylums board undertaking further work is that insured persons would resent being sent there and classed with pauper patients. This is only a sentimental objection, and would, if encouraged, defeat any comprehensive scheme for the treatment of all tuberculous persons.

A House of Commons Committee is inquiring into the sale of patent medicines. Last week it had before it the secretary and manager of a limited company dealing in proprietary articles, and asked him about advertisements of "Novel Beauty Receipts." The witness said there was only one director to the company, and he was at present in America, so he could not answer some of the questions put. The chairman read a list of names of ladies appearing in the advertisements and asked if witness had any knowledge as to whether such persons existed or not. He pleaded it was not for him as a servant to form an opinion. After some pressure, and a warning, he admitted "at the time when the letters were received I had an idea that one of the ladies named was an actual person." To a question when his directors met he answered, "There is only one director, and he meets himself." A solicitor appeared and asked to be allowed to state this was a small private company formed last year by Mr. Daniels, and in his absence the secretary was in an awkward position. He testified that he prepared the memorandum and articles of association of the company, and on formation 502 shares of £1 were issued, 501 to Mr. Daniels and one to his first secretary.

Mr. J. H. Targett, obstetric surgeon and lecturer at Guy's Hospital, has died after a long illness at the early age of 51. He was a Guy's student, and after qualification held the house appointments and the surgical registrarship. He was formerly pathological curator of the Royal College of Surgeons Museum, and at the time of his death examiner in obstetrics for the conjoint board. He was M.B. and M.S. of the London University, and Fellow of the Royal College of Surgeons. He made contributions to the literature, especially to *Guy's Hospital Reports.*

## TUBERCULOSIS IN FRANCE.

(From Our Insurance Correspondent.)

PARIS, May 31, 1913.

IN a recent article (January 11, 1913) we reported upon the favorable results obtained in Lyons, France, on the mortality from tuberculosis by the Antituberculosis Dispensary. We now shall show the other side of the question—that is, the increase in tuberculosis mortality in Paris due to unhygienic principles which should be stamped out.

In the *Journal des Médecins Accoucheurs* an article appears criticising the overcrowding in Paris, the unsanitary conditions existing in certain parts of the town and finishes by quoting glaring examples of the spread of tuberculosis in some blocks of houses in the old streets in the city.

Brouardel estimated that 150,000 persons died annually in France from tuberculosis, but this figure was criticised by Robin and Mirman, who gave an estimate of 85,000. There is no doubt that the figures given by Brouardel are more exact, still it is difficult in France to obtain exact figures owing in many cases to the reluctance of the medical attendant to certify tuberculosis as the cause of death.

From the statistics of 1910 we obtain the following figures of deaths from tuberculosis per 100,000: France, 217; Germany, 168; Italy, 166; Spain, 162; England, 146; Belgium, 139. In France 42 per cent. of the deaths occurring between the ages of twenty to thirty-nine are caused by tuberculosis.

In Paris City (within the walls) about 3,500,000 persons sleep every night, and of this number 500,000 come from their work in the suburbs into the town of Paris to spend the night.

In most cities the efflux at night to the suburbs is greater than the influx, but in Paris the reverse holds good. In 1896, there were 318 inhabitants per hectare (10,000 square meters) in Paris, whereas last year there were 370 for the same area.

The open spaces, such as parks, in a city are usually looked upon as the "lungs" of that city. In London, Hyde Park alone measures 240 hectares, whereas in Paris the Luxembourg, Tuileries, and Park Monceau amount to only 55 hectares in all, or in other words, only about one-quarter the "lung space" in comparison.

In the Lombard Quarter of Paris, 250 houses out of 276 are contaminated with tuberculosis; in the Brisemiche 22 people per 1,000 die annually of phthisis in the dwelling houses and the death rate in the lodging houses from the same disease is as high as 42 per 1,000. Several such examples might be quoted to show the conditions prevailing in some quarters of the city. In Paris 81 streets and 5,000 houses are infected with tuberculosis; 12,000 families of six persons live in single room apartments.

From the above it can be seen that there is considerable scope for measures similar to those carried out in Lyons and again we have an example of the "dollar and mortality rate problem."

---

**Smallpox on Steamship.**—The steamship Ryndam, which arrived in New York on June 18 from Rotterdam and Boulogne, was detained at Quarantine because of the discovery of a case of smallpox among her steerage passengers. The patient was transferred to Swinburne Island and 191 passengers who occupied the same compartment were sent to Hoffman Island for observation.

4. The Diagnostic Evidence Obtained by X-Rays from the Lateral Aspects of the Skull, with Especial Reference to the Base and Its Adnexa. P. Brown.
5. Social Pediatrics. I. S. Wile.

**2. The Human Gastric Juice and Various Digestive Remedies.**—G. H. Nofer concludes from his experiments that the normal gastric juice, when compared with various preparations of pepsin, pancreatin, and rennin, shows the greatest proteolytic power. Therefore, when there is a deficiency of the gastric juice, one should endeavor to reestablish the production of normal gastric juice, before replacing it by these various remedies. A practical inference suggests that when one prescribes pepsin one will probably get better results by ordering scale pepsin dispensed as a tablet, capsule, or in sealed packages, to be freshly dissolved in water and taken about a half hour after meals. If hydrochloric acid is indicated it may be dispensed separately and ordered to be taken well diluted. (All the scale pepsin solutions were freshly made at the time of the tests.) Undoubtedly pepsin, like other remedies, has suffered from being improperly dispensed and injudiciously used. Pepsin will not lift a fallen stomach; it will not cure the reflex gastric symptoms due to gall-bladder disease, chronic appendicitis. The crux of the whole subject depends upon that fascinating subject of diagnosis. The author's personal impressions are that pepsin's rôle in therapeutics will be established and enhanced by its exhibition on exact indications dependent on accurate diagnosis.

**3. Binasal Hemianopsia in Brain Tumor.**—W. B. Lancaster states that it is better to adhere to the classical conception of hemianopsia and require for admission to that category that the cases must show symmetrical losses limited (unless a complication is present) to a half field of each eye and due to a single lesion affecting the visual centers or pathways at or posterior to the semi-decussation of the optic nerves. Fields which simulate these, but are of totally different origin (glaucoma, atrophy, retinitis) may be called pseudo-hemianopic. The cases reported by Cushing and Walker as examples of binasal hemianopsia, when all the charts are combined into one composite chart to determine the type, show that the true type of loss of the visual fields is a concentric contraction affecting both half fields equally and therefore not to be called hemianoptic according to the accepted use of the term by ophthalmologists. The characteristic form of the visual fields in secondary atrophy is probably due to the distribution of the fibers in the nerve head. This distribution is such that the superficially located fibers are most exposed to the pathological processes and are the first to succumb while the deepest and most peripheral fibers of the papilla are the last to suffer. These come from the area of the retina adjacent to the optic disk, thus accounting for the tendency noted by Cushing and Walker "for the elds to become limited to a small bitemporal field surrounding each blind spot." Were this process complicated in some cases, as suggested by Cushing and Walker, by a pair of symmetrical lesions affecting the outer aspects of the optic nerves near the chiasm where the uncrossed fibers which come from the temporal retina are superficially situated, the damage to these fibers should show itself in a modification of the form of the visual fields. The loss from the nasal fields should exceed what we should expect to find, judging by the progress of the loss in the temporal elds. This does not seem to

occur. The last case in their series is probably an example of retrobulbar neuritis.

4. **Lateral Radiography of the Skull.**—P. Brown notes that the value of the proper Röntgen interpretation of the lateral skull, with reference to the accessory nasal sinuses, need not necessarily be dimmed by the more brilliant diagnostic offerings of the occipitofrontal position. The greatest importance should be laid upon the already established fact that this cranial plane is absolutely essential to the only important Röntgen diagnostic step in the pituitary region. Neither of these applications, however, can be made properly without an exhibition of the highest type of technical skill and diagnostic judgment.

10. Chronic Mediastinitis Following Osteomyelitis of the Sternum; Report of a Case and Operation. H. M. Armitage.

1. **Gonorrhea from a Pathological Standpoint.**—G. A. Wyeth concludes that gonorrhea, on account of its complications and sequelæ, must be recognized as a most serious infectious disease. It can be cured if the seat of infection is definitely located and scientifically treated. It can be aborted in a large proportion of cases if patients are seen early. In the acute state phagocytosis is the chief means of combating the infection. It should, therefore, be one's endeavor to promote a local leucocytosis by increasing the discharge. Time-honored astringent injections which aim to check the discharge are to be condemned as long as gonococci are present. Only by the systematic use of the microscope can one intelligently direct one's course of treatment.

2. **Trauma and Bone Tuberculosis.**—H. H. Wilson and R. C. Rosenberger believe that the relation of trauma to bone tuberculosis must, sooner or later, be established as having no existence in the etiology—or in the beginning of the process. The primary cause of bone tuberculosis is essentially infection by the bacillus of tuberculosis. Any condition which lowers the vitality, and therefore the resistance of the patient must be considered contributory.

4. **Freud's Psychology.**—M. J. Karpas believes that Freud's contributions to psychology are of eminent value. By his methods one is enabled to penetrate deeply into mental life, which one can study in all its phases and ramifications, be they normal or abnormal. His theories of sexuality are of great importance to the physician, psychologist, and educator. Formerly, the psychological manifestations of sexuality were neglected. In the field of nervous diseases, such as hysteria, compulsive neuroses, and allied conditions, the psychoanalytical method, as developed by Freud, can be successfully carried out under certain conditions and in cases suitable for such treatment. By the older methods, such as hypnosis, suggestion, or rest cure, it was possible to remove the symptoms, but not their underlying causes. Indeed, the fundamental principle in therapeutics is to remove the cause of the abnormal phenomena. In mental diseases Freud's method has aided one in understanding the psychology of psychotic symptoms, and hence has enabled one to understand the mechanism of functional psychosis. Thus rational prophylaxis can be intelligently instituted. It should be emphasized that no claims are made of curing dementia præcox, paranoid conditions, or other severe mental disease by psychoanalysis. Psychoanalysis bears the same relation to psychiatry that bacteriology does to infectious diseases

6. **Hallucinations of Hearing.**—J. H. W. Rhein reports three cases of hallucinations of hearing associated with disturbances in the peripheral auditory apparatus, in which the hallucinations were the only manifestation of mental disease. In all three cases described the possibility of arterial change in the brain must be recognized and especially in two of the patients, whose ages were, respectively, sixty-five and sixty-nine. It is difficult to avoid the conclusion that the nutrition of the auditory centers has been implicated in these cases and that, therefore, they react abnormally to peripheral irritation. While the occurrence of hallucinations of hearing associated with disturbances of the peripheral auditory apparatus does not necessarily indicate the onset of insanity, there can be little doubt that this phenomenon is an expression of an unstable psychic equilibrium and is therefore actually within the domain of psychiatry. A history of nervous disease in the ancestry is usual, and a study of the cases shows a tendency at some time to exhibit neuropathic manifestations.

1. **Typhus Fever in the United States.**—J. F. Anderson points out that typhus fever is more widespread in the United States than the figures would seem to indicate. While the disease as generally observed has had a low case mortality and no great tendency to spread, there is a possibility of its becoming virulent and epidemic. Guinea-pigs are quite susceptible to typhus when inoculated intraperitoneally with the blood of patients in the active febrile stage and the author suggests as a means of collecting more accurate data the use of such inoculations from the blood of patients with a continued fever giving a negative Widal and blood-culture; especially in cases of sudden onset, atypical eruption, intense headache, apathy, and prostration. He believes that such methods, if carried out, would prove that typhus is more prevalent in our large cities than is generally believed.

6. **The Luetin Reaction.**—J. M. Wolfsohn concludes on the basis of his observations, and of those of all previous workers, that the luetin test, when properly performed is specific for syphilis. Intensive antisyphilitic treatment in the latter stages of syphilis may produce a negative luetin reaction which, after an interval during which treatment is withdrawn, may become positive. Treated congenital and secondary syphilis is apt to give positive luetin reactions. The luetin reaction is especially valuable in parasyphilis, and tertiary and latent syphilis. In any case of suspected syphilis, where previously treated

or not, a negative luetin reaction must be watched for at least four weeks so that one may not overlook a delayed reaction.

9. **Gastric Dilatation.**—A. Frick notes that dilated stomach retains its contractility very well no matter for how long a time or to what degree it has been dilated. The chief purpose of the treatment of a gastric dilatation should be to give the dilated stomach every possible opportunity to contract. This purpose is best accomplished by the removal of the gastric contents, starvation, and rest in bed. These three therapeutic measures should be considered a distinct method of treating gastric dilatation, and are indicated as soon as a diagnosis of dilatation has been made, just as the starvation cure is considered a method of treating gastric ulcer. This method is indicated as a preparatory treatment in those cases of gastric dilatation in which a gastroenterostomy is to be made on account of the cause which has led to dilatation, as under such treatment the stomach will contract as far as possible and an eventual continuous gastric secretion will cease. Intragastric or extragastric electricity, massage, cold compresses, or other hydrotherapeutic measures, abdominal supporters, rectal feeding, strychnine, antiseptic drugs, and alkalies are valuable auxiliary remedies but are not strictly necessary for the treatment of gastric dilatation.

11. **Ocular Findings and Longevity.**—W. C. Posey states that marked ocular disturbance from diseases elsewhere in the body indicates a development seriously threatening health and life. The discovery of hemorrhages in the retina, for example, when not of traumatic origin, in any adult should always be considered as indicating a serious condition. Death may be expected from one to three years in albuminuric retinitis. Future statistics may show some improvement. A carefully regulated manner of living with the best of medical care may prolong life for many years. Of almost equal value to the examiner is the recognition of the ocular symptoms of diabetes which are many and varied. The most important are the changes in the ciliary muscle, the lens and the retina, which changes not infrequently are the first recognized symptoms of diabetes mellitus. With proper care diabetics may live many years after the development of ocular lesions and these may sometimes improve. Diabetic cataract is the one form of cataract that yields in any degree to inoperative measures. The ophthalmoscope may also give valuable indications in the retinal circulation, both as regards the conditions of the heart and also as regards the prospects of life. Lead, tobacco and alcohol often reveal their defects in the fundus oculi, and syphilis can affect almost all the eye structures. Tuberculosis has also its eye symptoms. The earliest symptoms of paresis are often ocular and may be of the greatest value in diagnosis. Aside from the question of life expectation, the author thinks insurance examiners should give more attention to the degree of visual acuity as affecting a person's capacity for work.

1. **Industrial Accidents and Diseases.**—By Sir Thomas Oliver. (See MEDICAL RECORD, Vol. 82, page 821.)

3. **Diagnostic Value of Tuberculin.**—N. D. Bardswell states that in healthy persons the tuberculin reaction is of no clinical significance, and that in a case of ill-health a reaction to tuberculin is, in itself, no evidence that tuberculosis is the cause of the symptoms. In brief, it is generally recognized that so far as pulmonary tuberculosis is concerned tuberculin for diagnostic purposes has great limitations, since a reaction occurs as readily in cases of mere infection with tuberculosis (non-clinical tuberculosis) as in clinical tuberculosis, and in respect to clinical tuberculosis we are unable to differentiate with any certainty by the use of tuberculin between cases of active, quiescent, and arrested disease. There are, however, good grounds for holding that in the case of a patient presenting indefinite signs and symptoms the failure to react to a subcutaneous dose of 10 milligrams is strong evidence against the existence of clinical tuberculosis, and that conversely the occurrence of a focal reaction in a suspected area in the lungs is suggestive of the existence of potentially active tuberculous disease.

6. The Position and Form of the Normal Human Stomach. A. M. Paterson.
7. A Note on the Shape of the Normal Empty Stomach. J. S. B. Stopford.

1. **A Clinical Study of Pneumonia.**—J. A. Lindsay presents an analysis of one hundred consecutive cases of pneumonia that he treated at the Royal Victoria Hospital, Belfast. The general mortality was 20 per cent., which is roughly the average mortality of the disease in general practice. As to the prognosis in this disease, the author states that this is determined mainly by the following factors: (a) The patient's age; this dominates the outlook. (b) The amount of lung involved. Double pneumonia is very deadly. (c) The general character of the symptoms. Marked cerebral involvement is very serious. Very high temperatures are grave, while abnormally low temperatures may indicate either a mild attack or deficient reaction. The latter is common in the aged and alcoholic. Slight febrile albuminuria has little weight, but signs of marked renal congestion are serious. (d) The nature of the complications. Gangrene and abscess of the lung are very serious. Pericarditis is a grave complication, and malignant endocarditis carries with it an almost certainly fatal issue. Meningitis is another rare complication which usually involves death. One should treat pneumonia on the lines of the acute general infections, remembering the intensity of the toxemia, its self-limitation and relatively brief duration, its tendency to depress the heart and cause circulatory failure, the increase of the fibrin elements in the blood, the importance of a fortifying line of treatment and of avoiding all depressing measures. The problem of specific treatment still awaits solution.

2. **Radium in the Treatment of Malignant Disease.**—R. Knox concludes that in all cases of early cancer the operative method is undoubtedly the best; it is quicker and safer, and offers the best prospect of cure. 2. Radium is a useful adjunct to the treatment of all cases, first as a prophylactic after operation, and, failing operation, the next best method one possesses. It must, however, be stated that *x*-rays are in selected cases quite as useful as radium. In patients who refuse operation, or are for other reasons not suitable for operation, radium is a useful remedy. In inoperable cases radium may help to render the case operable; and, failing that, is undoubtedly useful as a palliative measure.

3. **Diachylon as an Abortifacient.**—Sir Thomas Ol-

iver states that the self-administration of diachylon pills by pregnant women for the purpose of procuring abortion is a practice more widely indulged in and with more serious consequences than at first sight appears. The dangers following the self-administration of diachylon are not only that the woman may have a long and painful illness, accompanied or not by paralysis of hands and limbs, but that she may die in the attack of acute plumbism, either from intractable vomiting, acute inflammatory affections of the pelvis consequent upon incomplete abortion, or from convulsions. Young females, married and unmarried, have been admitted into hospitals or been treated by medical men outside, and have died in convulsions or from recurrent vomiting, and at the post mortem examination nothing has been found to explain either the symptoms or the death. In a few of these it was afterwards ascertained that diachylon had been taken.

4. **The Celluloid Jacket.**—H. J. Gauvain notes that jackets made of this material are light, elegant, rigid but slightly elastic, strong, are not acted upon by the heat and moisture of the body, maintain their shape indefinitely, and are comparatively easy to make. Their greatest value lies in the fact that they may be made to accurately fit a cast of the patient and maintain the shape of this cast indefintely. The great objection to the use of celluloid is its inflammability. It has been discovered, however, that if a supersaturated solution of calcium chloride in very hot water is added to the celluloid dissolved in acetone, the resulting mixture when dry is absolutely non-inflammable. It retains its non-inflammability when made into a splint, and such a splint cannot be made to burn even when held in a fire. This discovery, therefore, disposes of the greatest, and indeed the only, objection which can be raised to the employment of celluloid in the manufacture of orthopedic appliances.

6. **Form and Position of the Normal Stomach.**—A. M. Paterson from personal observations is of the opinion that the normal stomach is, in the majority of cases, a four-chambered organ, composed of the following parts: Cardia and fundus, pyloric vestibule, pyloric antrum and pyloric canal. The constriction forming the pyloric vestibule between the cardia and pyloric antrum may form a definite tubular canal, or it may be a deep V-shaped notch in the greater curvature, producing often atypical hour-glass contraction. There is usually a considerable thickening of the muscular wall of the organ in relation to the pyloric vestibule and the pyloric canal.

## Münchener medizinische Wochenschrift.

*May 27 and June 3, 1913.*

**Fatal Cerebral Hemorrhage in Hemophilia.**—Hauck mentions the two types of apoplexy seen in hemophilics. One is conditioned by some sort of trauma, including injuries not readily demonstrable. Conceded the friability of the cerebral vessels the nature of the injury is of secondary significance. A mild, blunt injury may be sufficient to cause a trauma. This is also well seen in connection with joint injuries. In the other type the hemorrhage is termed spontaneous, for want of evidence of trauma of any kind. In a case history given the age of the patient—but 20 years—is sufficient to exclude apoplexy from the usual causes. He came of a family of bleeders, and was in good health prior to the prodromes of the apoplectic attack. These consisted of repeated attacks of headache and vomiting. The medical attendant, knowing the family infirmity, sought in vain for evidence of violence. There was a history of hemarthrosis and other losses of blood. The patient received a thorough examination which revealed evidences of intracranial pressure. There was no paresis but it was surmised that blood could have escaped into the ventricular cavity, for the lumbal punctate contained pure blood. An epileptiform convulsion developed suddenly and patient succumbed without the development of hemiplegia. The author is unable to find a parallel case in literature, *i.e.* of spontaneous hemorrhage. Autopsy showed escape of blood in numerous localities in the brain—meningeal, parenchymatous, etc.—which explained the absence of paresis of focal origin.

**Erythema Nodosum and Tuberculosis.**—Moro refers to a recently made claim by Pollak that he obtained evidences of tuberculosis in 100 per cent. of his cases of erythema nodosum, relying chiefly on positive reactions to tuberculin. The author, in attempting to verify this find, obtained four negative results in thirty patients tested. He has long held that a close connection exists between the two conditions, but to look upon erythema nodosum as purely a tuberculide is to go much too far. Tuberculous toxins are one but not the sole cause. The line of proof offered is simply that the ointment reaction of tuberculin named after the author is able to produce erythema nodosum; but it has also been seen to provoke zoster and purpura. No one has yet caused a focal reaction in lesions already present, nor has the bacillus yet been found in the lesions.

**Syphilitic Pernicious Anemia.**—Weicksel relates a case of this type in a patient aged 52. There was evidence of past syphilis in the family, but patient himself had only a local sore during his military service. He had kept well always until quite recently when he became suddenly weak and pale. The symptoms were those of anemia of severe character and the blood count showed this to be pernicious with a positive Wassermann. Patient was given an injection of salvarsan, repeated after some days, but no real improvement set in and a bronchitis very nearly terminated his existence. After hovering near death for three weeks he began to improve slowly and eventually recovered save for the sense of prostration. Aside from salvarsan the patient had taken iodides and Fowler's solution. The nature of the cure was paradoxic, and the author is evidently not entirely certain as to the syphilitic etiology of the case.

**Hypotonia of the Eyeball in Diabetic Coma.**—Hertel states that the cause of this phenomenon has never been explained satisfactorily. The author writes briefly in the interest of his priority claim for the elucidation of the nature of the occurrence. This is not bound up with the existence of a diseased state of the eye, nor does it in any way depend upon the blood pressure. The author discovered that the electrical conductivity of the softened eye indicated some alteration in the osmotic relations, and proceeded to vary by means of intravenous injection of various substances the molecular concentration of the blood. Ehrmann had already called attention to the imperial observation that the butyrates (supposedly involved in acidosis) could increase the intraocular tension. The author verified this claim for the butyrate (and isovalerianate) of soda. Animal experiment has, to sum up, shown conclusively that certain changes artificially produced in the blood lower the intraocular pressure. These data should be sufficient for a successful research of the subject. The substances which alter the concentration of the blood are in nowise specific. The main thing is to employ some one of several substances (sodium chloride) in such amounts as to secure a certain concentration.

**Abderhalden's Serodiagnosis in Psychiatry.**—Wegener, who is Binswanger's assistant, speaks very encouragingly of the future of this new resource, which has been tested in 200 cases. In insanity of youth the blood serum disintegrated in females both ovaries and tubes, but not the testicles; in males it disintegrated testicular substance only. In manic-depressive insanity no tissues were attacked. In epilepsy with beginning dementia brain substance is decomposed. In all the luetic and metaluetic affections, the same result was obtained. Abderhalden's test is also shown

to be at times more delicate than the Wassermann. In a few cases of neuritis the blood serum disintegrates muscular substance. Binswanger has at his disposal tissue substances of every conceivable character, for serum tests. Abderhalden in this line of work began with placental substance for testing the blood serum of gravidity.

**Commercial Placental Powder for Abderhalden's Pregnancy Test.**—V. L. King, head of an American laboratory, inspired by the attempts of Lindig of Jena, which, however, gave at first an impracticable product, has devised a process for the manufacture of a dry-permanent powder. This, which is adapted for dialysis process, is conceived along Abderhalden's original lines in preparing his reagents. The powder is obtained by evaporation and rendered stable by toluol. The essential step in preparing the powder is the use of acetone, which simultaneously rids the placental tissue of fat and water. Tests made with this powder are said to be more delicate than when unchanged placenta is used.

**Hematological Diagnosis of Rötheln.**—Schwaer has introduced a clinical blood test which should prove of great value in both diagnosis and differential diagnosis. There were three cases under treatment which imposed themselves clinically as measles, but the first soon proved itself rötheln. Two weeks later two similar cases were admitted. At this juncture it occurred to the author to compare the blood counts of the cases with examples of true measles. It was found that in rötheln at the high point of the disease there is none of the disappearance of eosinophiles, which characterizes measles; nor is there the leucopenia regarded as normal for the latter.

## Deutsche medizinische Wochenschrift.

*May 29, 1913.*

**Two Cases of Eclampsia Cured with Hypophysis Extract.**—Schlossberger gives only the bare details of the cases which he terms an addition to those cured by conservative methods. Case I, aged 42; V-para; seizures began 1 a. m. on Nov. 19. When seen patient comatose, cyanotic. Gestation had reached term, but there were no pains. Os closed. Albumin, 5%. Sodium chloride retention. Patient received 1.19 hypophysis extract and 0.02 pantopon. The convulsions, which had been continuous from the first, ceased within a half hour. At 4 a. m. she became conscious, and the os was found to admit a finger. A second injection of hypophysis extract now given. At 6 a. m. a healthy child was expelled, and placenta followed in 5 minutes. Mother completely recovered but showed trace of albumin for months. The second patient was 23, II-para. Gravid in sixth month. Convulsions set in 11 p. m., Mar. 22. Unconscious, attacks of convulsions incessant. Face swollen, legs edematous. Pulse 140, small. Anuria. Os closed. Digitalis and diuretin given per os were vomited. Hypophysis extract and pantopon injected in same quantities as in first case and convulsions ceased within three-fourths of an hour. At 2 a. m. os admitted finger. Diuresis reappeared, urine containing an abundance of albumin. Second injection of hypophysis extract. At 4 a. m. six months' fetus expelled alive with placenta immediately following. Fetus survived 15 minutes. Patient fully recovered in 8 days, and the last traces of albumin disappeared in four weeks.

**Modern Styptics.**—Gisel enumerates in succession ergot preparations, hydrastis, styptol and stypticin, gelatin, horse blood serum, mammin and hypophysis extract. He next refers to attempts to combine some of these to form others of special merit. Styptol and stypticin are of course familiar names for certain salts of cotarnin. The ergots, cotarnins and hydrastin all act upon uterine hemorrhage. Stypticin is prepared by oxidizing narcotin, and in animal experiment seems akin to strychnine. Stypticin and styptol are both related to hydrastinin, which is derived from hydrastin, the active principle of hydrastis canadensis. Cotarnin is literally oxymethylhydrastinin. Stypticin as a derivative of narcotin possesses mild sedative powers. The cotarnins and hydrastins being thus affiliated may well be combined with some ergot preparation. The latter are multiple, having in part distinct properties. Some, of active principles, act as synergists with styptol. A decidedly improved styptic has been recently formed with a trade name from the ergot derivative secacornin and synthetic hydrastinum. It promises well, but thus far has been tested only by the author. It is recommended for any purpose in which an internal hemostatic is indicated.

**Extirpation of Spleen and Left Kidney; Complete Recovery.**—Mühsam relates a remarkable case in a boy aged 9 who had been run over. Patient found in deep shock, urine bloody. The evidences of peritoneal initation were present in a high degree and it was found that the kidney had prolapsed into the abdominal cavity, and all showed a complex injury. The belly was opened and active bleeding was seen to be present from the spleen. The latter organ was first extirpated after ligation of the vessels. The displaced kidney had not been ruptured but was contused; and, since the loss of a few more ounces of blood might have proved fatal, this organ was also tied off. The patient's organs were seriously impaired at first (blood count, remaining kidney-blood left behind in peritoneal cavity) so that the complete recovery eventually made was the more surprising.

---

**Acholuric Jaundice after Splenectomy.**—W. Essex Wynter reports the case of a woman, aged 22, who had been jaundiced in varying degrees since birth, and who exhibited a large hard spleen which caused dragging pain in the left side. Splenectomy was performed. The incision was nearly vertical, about two inches to the left of the middle line. The spleen was much enlarged, weighing three pounds, and showed a deep sulcus due to the gastrosplenic omentum, simulating the hilum. All the mesenteric attachments were clamped and divided, the vessels being at once ligatured. The spleen was then removed. Not more than two ounces of blood were lost, chiefly from the spleen itself. The under surface of the diaphragm was found healthy and free from adhesions. The incision was approximated with "through-and-through" stitches; three buried sutures being left. Recovery was rapid, the temperature varying from 99° to 100° F. for a week and then remaining normal. Jaundice, which had diminished during a previous three weeks' stay at Clacton, had been entirely absent since the operation, and the pains in the left side had disappeared.—*Proceedings of the Royal Society of Medicine.*

**Arteriosclerosis with Absence of Both Radial Pulses in a Girl Aged 15 Years.**—C. W. Chapman reports the following case: F. G. complained of cough and orthopnea on exertion or exposure to cold. There was rheumatism on the mother's side. History: No special illness until four years ago, when she suffered from loss of power in the legs with loss of speech, the attack lasting fifteen minutes. There were several similar attacks during the following six months. Bronchitis two years ago. She is said to have had chalky lumps on her abdomen last summer. When first seen the area of cardiac dullness was increased in both directions, that on the left side being 9 cm. beyond the midsternal line; the apex beat was in the sixth space at the extreme margin of the dullness. The finger-tips were slightly congested. Catamenia not commenced. Teeth very bad. On admission the cardiac dullness was as stated; the subclavians were visibly pulsating, and aortic pulsation could be felt by the finger in the aortic notch, the brachial and radial arteries were hard and devoid of pulsation, the iliac arteries were visibly pulsating, but only feeble pulsation could be felt at the left posttibial and not at all on the right; the apex beat was in the sixth space and the action cantering. Urine: Specific gravity 1022, albumin a trace, sugar absent, no casts or red blood cells. Wassermann reaction negative. Since admission to the hospital the child has gained weight and has generally improved; the cardiac dullness is diminished and she can lie down in comfort. There is still a cloud of albumin. The skin on the abdomen is dusky, but no cyanosis or blanching is present.—*Proceedings of the Royal Society of Medicine.*

# Insurance Medicine.

## INSURANCE AND EUGENICS.

To the Editor of the Medical Record:

Sir:—I would like to propose for your consideration the advisability of a new line of insurance. There is a demand that those about to marry should furnish a certificate of health as a necessary preliminary. The present agitation seems to be confined to certain religious and social organizations, although one or two of the State legislatures have passed laws requiring such certificates. The important problem is who shall furnish such certificates? There will be many solutions. The certificate of the general practitioner is of doubtful value. A public bureau of experts responsible to the State will probably be necessary to furnish certificates which will be within the reach of a large proportion of our citizenship. The ideal source from which such certificates should issue would be a surety company, the reliability of whose certificates would be ensured by the responsibility of the company, which would not only furnish the certificates but would insure against any error on the part of its examiners.

It does not require much argument to prove that in no other way can we have certificates that are of any value, either for the primary object of protecting the individual or for the secondary object of improving the race.

Such certificates might be of two kinds: first, the ordinary kind to protect the individual should guarantee against the presence of contagious venereal disease and tuberculosis; second, there could also be issued eugenic certificates, based upon the study of the heredity of the applicant, showing the tendencies to certain degenerations and indicating the proper inheritance to be looked for in the wife or husband, as the case may be, so as to insure with the greatest probability the production of healthy offspring, with a tendency to ascend rather than to descend. Of course this is but a step to breeding for certain qualifications, for which proper insurance might be issued. But this is rather fanciful and chimerical.

Thomas W. Harvey.

Orange, N. J.

---

**Prognostic Value of Slight and Transient Albuminuria.**—The presence of even a trace of albumin in the urine of applicants for insurance, seems to be the rock upon which the opinions of many of the insurance companies split, some viewing the condition with leniency, while others regard it with inflexible rigidity, much to the chagrin of the discomfited applicants. Henry W. Cook, Medical Director, Northwestern National Life Insurance Company, Minneapolis, Minn., states that in applicants over forty or fifty years of age it is of great importance to determine the presence or absence of even a slight albuminuria, as at this period of life it is indicative of more serious physical impairment elsewhere in the body; that the slighter degrees of albuminuria are almost constantly overlooked by the average examiner; that apparently the only way to obtain this very vital information is to have the uranalysis made at the home office, although an improvement can be expected from the recommendation to the examiners of the use of a more delicate and simpler test. The inability of the average practitioner to find albumin by the tests now ordinarily used—Heller's and the heat and acid test—is, however, subject to daily and hourly demonstration. Heller's test, while well suited for the laboratory expert, is most misleading with the careless, hurried work of the general practitioner. The care, the time, the light, are wanting, and the fine white line which could have been distinguished after half an hour's wait in a conical glass, in a bright light by trained eyes, is overlooked in the back office, after a hurried glance through a soiled test tube by unaccustomed eyes, confused by the dark pigment line or the cloud of urates. For a more accurate test the author recommends Ulrich's modification of the saline acid test, as being simple and delicate, and giving the positive reaction immediately. An acidulated saturated solution of chemically pure common salt is the only reagent required. The method is simplicity itself. Boil in a clean test tube several cubic centimeters of a saturated and filtered saline solution, acidulated to 1 per cent. with acetic acid. Overlay this with the urine, and if albumin is present even in small traces, a white line is readily seen at the point of contact. The relative delicacy of this test is indicated by the report often received; positive by saline test, absent by Heller's. A home office examination of the same specimen shows albumin distinct by all tests. Thus a general use of a more delicate test would give a clearer knowledge in a larger proportion of cases than is obtained at present. The author further states that it is to be expected that insurance companies should be in a somewhat chaotic state with regard to those medical points that are changing from time to time, and judgment has to be varied to meet existing conditions. Albuminuria cases, in which albumin is present in large quantity, cannot be accepted at standard rates, but to refuse a young farmer who had been plowing all day and had a trace of albumin in his urine afterward, or a young man who takes a cold bath every morning and shows a trace of albumin in his urine afterward, would be extreme and absurd. These are by far better risks than the man who sits at his desk all day and does not show albumin. As methods improve, so must judgment of these cases, and the better the uranalysis to discover the final process the better the judgment in reaching a favorable decision.—Medical Section, American Life Convention, February, 1913.

**American Association of Medical Examiners.**—The following officers were elected at the annual meeting of the American Association of Medical Examiners, which was held at the Hotel Radisson, Minneapolis, Minnesota, June 16: *President*, Dr. Henry Wireman Cook, medical director, Northwestern National Life Insurance Company, Minneapolis, Minn.; *Vice-President*, Dr. A. T. Gaillard, medical referee, Travelers' Insurance Company, Philadelphia, Pa.; *Second Vice-President*, Dr. W. W. Tompkins, Charleston, W. Va.; *Third Vice-President*, Dr. J. W. Guest medical inspector, Equitable Assurance Society, Louisville, Ky.; *Fourth Vice-President*, Dr. James H. Stowell, medical director, North American Life Insurance Co., Chicago, Ill.; *Secretary and Treasurer*, Dr. G. Strohbach, Cincinnati, Ohio.

This Association was organized in 1900, its objects being: (1) To bring about a more cordial cooperation between medical directors and medical examiners. (2) To encourage scientific work and study by medical examiners in their particular field. (3) To record and report the result of such work and study. (4) To enhance the efficiency of medical examiners.

# Book Reviews.

Tuberculin in Diagnosis and Treatment. By Louis Hamman, Associate in Medicine, and Samuel Wolman, Instructor in Medicine, both of the Johns Hopkins University. 381 pages. New York and London: D. Appleton & Co., 1912.

This book is dedicated to Henry Phipps, the founder of the Phipps Tuberculosis Institute of Philadelphia and of the Phipps Tuberculosis Dispensary connected with Johns Hopkins Hospital in Baltimore. It is a volume of nearly 400 pages and the first complete book of its kind written by American authors. Although they have drawn matters of value from the works of others, much of the contents of the book is based on the results of the authors' own work and experience. The scientific principles underlying the diagnostic and therapeutic use of tuberculin are carefully and impartially discussed in Chapter I. The choice of tuberculin, the preparation of tuberculin dilutions and the technique of the various tests are thoroughly considered in the subsequent chapters. Somewhat surprising to the reviewer is the tenacity with which the authors still cling to the conjunctival or ophthalmic tuberculin test. As is well known, most workers in tuberculosis have abandoned this method of using tuberculin for diagnostic purposes. When one bears in mind that slight ophthalmic troubles are not always recognized by the busy practitioner and that the instillation of even only a one per cent. solution is sure to aggravate an inflammatory process of the eye, it would seem unwise to continue with such tests, particularly when the safer cutaneous tests can be applied and equally good results obtained. The authors quote Baldwin as having made over a thousand instillations without any untoward results, but it must be remembered that he uses only a half per cent. solution of the precipitated tuberculin prepared by himself. In connection with the dangers from the ophthalmic test in general one must also bear in mind the tendency of older people to conjunctival inflammation and corneal ulceration. The authors themselves emphasize this latter fact in a chapter devoted to the dangers of tuberculin and here also add the well-known fact that a conjunctival instillation of tuberculin, whether there be a reaction or not, often renders subsequent administrations of tuberculin subcutaneously for diagnosis or treatment, if not dangerous at least unpleasant.

The portion of the book devoted to tuberculin as a therapeutic agent is excellent and, besides the well-known subcutaneous method, describes the newer oral, intrabronchial, rectal, cutaneous, percutaneous, intravenous, and intrafocal routes. All in all, it may be said the authors have succeeded in what they have aimed at—in producing a book that may serve as guide to those interested but inexperienced in the use of tuberculin and as a source where reliable if not exhaustive information on the subject may be sought.

Organic and Functional Nervous Diseases. A Text-Book of Neurology. By M. Allen Starr, M.D., Ph.D., LL.D., Sc.D. Professor of Neurology, College of Physicians and Surgeons, the Medical Department of Columbia University in the City of New York; Consulting Neurologist to the Presbyterian Hospital and to St. Mary's Free Hospital for Children; ex-President of the American Neurological Association and of the New York Neurological Society; Corresponding Member of the Société de Neurologie, and of the Société de Psychiatrie de Paris; of the Neurological Section of the Royal Society of Medicine, London, and of the Gesellschaft Deutscher Nervenärzte; Author of "Familiar Forms of Nervous Disease," "Brain Surgery," and "Atlas of Nerve Cells." Fourth Edition, Thoroughly Revised. Illustrated with 323 Engravings in the Text and 30 Plates in Colors and Monochrome. Price $6.00. New York and Philadelphia: Lea & Febiger, 1913.

The demand for another edition of this book gives Dr. Starr an opportunity for a careful revision of its contents, for many additions, and also for an arrangement which should make it of greater value to the student and practitioner. The general aspects of neurology, the method of examination of a patient, and the principles of diagnosis have been brought together in the first part. The various symptoms presented by nervous affections are there described and analyzed; the practical anatomy and physiology of the nervous system, necessary to their understanding, are concisely set forth, and the attempt is made to trace each symptom to its underlying disturbance of function in a definite nerve center or nerve tract. In part second the organic diseases are taken up and such additions as have been made to their knowledge in the past three years have been incorporated. The chapters upon poliomyelitis and syphilis of the nervous system have been rewritten. Much new material has been added to the chapter on tumors of the brain; and pellagra has been discussed. In part third functional diseases are fully presented, the space allotted to this department having been more than doubled. Fuller discussion is given to spasmodic neuroses, especially to the various forms of tic and myoclonus. Some functional paralyses, myatonia congenita, myasthenia gravis, and family periodic paralysis have been presented. Psychasthenia is considered apart from neurasthenia, and the subjects of the conscious and subconscious mental activities, of suggestion, and of psychoanalysis, and of hypnosis are fully discussed. In part fourth the diseases of the sympathetic nervous system are discussed; chapters have been added on symmetrical gangrene and angioneurotic edema. Trophic symptoms occurring in nervous disorders are also presented. Personal observation and experience in the presentation of each subject have been utilized.

Skin Grafting for Surgeons and General Practitioners. By Leonard Freeman, B.S., M.A., M.D., Professor of Surgery in the medical department of the University of Colorado; Surgeon to St. Joseph's Hospital, the national Jewish Hospital and the City Hospital, Denver, Col. With 24 illustrations. Price $1.50. St. Louis: C. V. Mosby Company, 1912.

This book contains in small space the essential features of this branch of surgery, together with excellent illustrations. The author opens with a cursory history of skin grafting, from the time of the Hindus, 2,000 years ago, to the work of modern times begun by Reverdin in 1869. Reverdin's method is clearly set forth, the size of grafts, the placing of them, dressings, etc. Thiersch's method is next described in detail and Freeman considers it the simplest and most reliable as well as the one usually employed in cases of contractures, scars, etc. A review is given of the Wolfe-Krause method as first used by Wolfe in cases of ectropion and as modified by Krause. Hirschberg's skin-periosteum-bone method is also described. Different anomalies in skin-grafting are discussed, but the Thiersch method is reverted to in almost all cases. Anesthesia and all details are gone into together with a complete review of the literature exclusive of the excellent work recently done at the Rockefeller Institute.

On Alcoholism. Its clinical aspects and treatment. By Francis Hare, M.D., medical superintendent of the Norwood Sanatorium, Beckenham. Philadelphia: P. Blakiston's Son & Co., 1913.

This book is based upon a large sanatorium and hospital experience and treats not only of the medical side but to some extent of the psychology underlying this state. Hare believes that alcoholism should not be called a disease, as it may be diminished by voluntary effort. He describes the causes of it as extrinsic (grief, etc.) and intrinsic (mental depression with raised blood pressure, asthma, dysmenorrhea, etc.). He divides the clinical manifestations into two classes—recurrent and continuous. The former group contains dipsomania and pseudodipsomania and the latter, chronic inebriety and chronic sober alcoholism. The symptoms are next set forth, among which albuminuria is given as an index to oncoming alcoholic accidents. The corollary of tolerance is epigrammatically described as the intolerance of sudden withdrawal. Intolerance may amount to pathological drunkenness or mania-à-potu. Hare agrees with the lay opinion that sudden withdrawal is dangerous and discusses delirium tremens and alcoholic epilepsy. He agrees with Jauregg's theory that delirium tremens is due to an anti-alcohol formed in the system. He then discusses treatment as to tapering, rest, drugs, etc. The book is a well-rounded out discussion, interestingly written.

Systematic Case-Taking. A Practical Guide to the Examination and Recording of Medical Cases. By Henry Lawrence McKisack, M.D., M.R.C.P. London. Physician to the Royal Victoria Hospital, Belfast; Author of "A Dictionary of Medical Diagnosis." Price $1.50 net. New York: Paul B. Hoeber, 1913.

In this work the ordinary syllabus of case-taking is amplified into a short manual, which not only indicates the steps to be taken by the clinical clerk in order to obtain the information he has to record, but which also discusses the diagnostic significance of the various symptoms discovered. This small handbook will certainly prove useful, containing as it does a description of the various means for the investigation of disease, and can be read with profit by every practitioner.

Solidified Carbon Dioxide in the Successful Treatment of Cutaneous Neoplasms and Other Skin Diseases, with Special Reference to Angioma, Epithelioma, and Lupus Erythematosus. By Ralph Bernstein, M.D. Clinical Instructor in Skin Diseases, Hahnemann Medical College, Philadelphia, Pa.; Consulting Dermatologist to the Woman's Southern Homeopathic Hospital, Philadelphia, Pa.; Consulting Dermatologist to the J. J. Lewis Crozier Hospital and Home for Incurables, Chester, Pa.; Consulting Dermatologist to House of Detention for Juveniles, Philadelphia, Pa.; Dermatologist to West Philadelphia General Homeopathic Hospital and Dispensary; Dermatologist to Hahnemann Hospital Dispensary, Philadelphia, Pa., etc. Fully illustrated. Hammond, Ind.: Frank S. Betz Co., 1912.

The author's intention is to present the subject as briefly and as concisely as is possible with clearness, and to give in a practical way the results of his clinical experience in the treatment of various cutaneous manifestations for which he has found solidified carbon dioxide an admirable agent. In this little work of less than one hundred pages he considers the origin of carbon dioxide as a therapeutic measure; general considerations; explanation of its action on the skin; superiority over other methods of procedure; method of solidifying; applications, and therapeutics.

Safeguarding the Special Senses. General Advice Regarding the Use and Preservation of the Eyes, Ears, Nose, and Throat. By Henry O. Reik, M.D., formerly Associate in Ophthalmology and Otology in the Johns Hopkins University, and Surgeon in the Baltimore Eye, Ear, and Throat Hospital, Baltimore, Md. Illustrated. Price 75 cents net. Philadelphia: F. A. Davis Company, 1912.

In view of the fact that specialists are constantly crying to the family physician and to the public that prevention is not only cheaper but easier and better than cure, this volume is written to point out to the person of average intelligence that proper care of the eyes in early life prevents the onset of cataracts and other intraocular diseases in old age, and that the removal of diseased tonsils and adenoid growths permits the child to develop normally; and furthermore that proper attention to colds in the head and early treatment of running ears would wipe out 80 per cent. of the cases of brain abscess and purulent meningitis.

Leitfaden der Praktischen Kriegschirurgie. Von Dr. W. von Oettingen, Chirurg in Berlin-Wilmersdorf. Price 9.50 marks. Dresden und Leipzig: Verlag von Theodore Steinkopff, 1913.

In case of declaration of war there is very little time for the members of the medical profession who enlist to familiarize themselves with military surgery, and for this reason this book is published, containing a concise, general, and special consideration of the injuries sustained in war and their treatment by one who obtained his experience in the Russian-Japanese war.

Die Luetischen Erkrankungen der Bauchorgane. Von Hofrat Dr. Th. Hausmann in Rostock (vormals in Orel und Tula). Price 1.80 marks. Halle a. S.: Carl Marhold, 1913.

The author believes that this little monograph, the first of its kind in the literature of the subject, fills a need in the consideration of abdominal syphilis, for since Neumann's publication on "syphilis," sixteen years ago, this branch of internal medicine has not been taken up again thoroughly. Lues of the elementary tract, pancreas, liver, and spleen are discussed, while that of the kidneys is omitted. Of special interest are the chapters on retroperitoneal and mesenteric tumors and lues of the peritoneum. Syphilis of the stomach receives the most attention because of the scant notice given to it in text books and manuals.

Elementary Biology, Plant, Animal, Human. By James Edward Peabody, A.M., Head of the Department of Biology, Morris High School, Bronx, New York City; Author of "Studies in Physiology" and "Laboratory Exercises in Anatomy and Physiology," and Arthur Ellsworth Hunt, Ph.B., Head of the Department of Biology, Training High School, Brooklyn, New York City. Price $1.25 net. New York: The Macmillan Company, 1913.

In the preparation of this textbook the authors have succeeded to an unusual degree in the selection of such material from the vast field of biology as tends to unify the study of plant, animal, and human biology. The experimental work is well chosen and the way in which the scientific side of the experiments sets forth the practical bearings of the subject is especially to be commended. The authors have been fortunate in securing the assistance of many well-known biologists. As an elementary work this textbook is far superior to others which have come under our notice.

Mendel's Principles of Heredity. By W. Bateson, M.A., F.R.S., V.M.H.; Honorary Fellow of St. John's College; Director of the John Innes Horticultural Institution. Price $3.50 net. Cambridge: At the University Press; New York: G. P. Putnam's Sons, 1913.

This is the third impression, within four years, of a valuable book. It does not differ much from previous editions except in the correction of errors and the addition of certain appendices in which the author has tried to keep the subject abreast of the times. As a matter of fact, a future revision is hinted at by the author, a knowledge of such subjects as "heredity of sex," "coupling and repulsion," etc., being at present really in a transition stage. The object of the book, the author states in his preface, is to give a succinct account of discoveries in regard to heredity made by the application of Mendel's method of research. By the adoption of the Mendelian principles the study of heredity has become an organized branch of physiological science. The Mendelian principles are thoroughly discussed by Professor Bateson, and a suggestive chapter is devoted to their practical application. There is apparently no limit to such practical applications. The author foresees for them, for example, "not merely advances in the art of breeding animals and plants, but a control over the destiny of our own species." Speaking of Mendel himself he says: "The types of the great discoverers are most various. The wild, uncertain, rapid flash of genius; the scattered half-focused daylight of generalization; the steady, slowly perfected ray of penetrative analysis—are all lights in which truth may be seen. Mendel's faculty was of the latter order." His work was long lost to the world, but its acceptance at the present day justifies his early confidence when he said: "Meine zeit wird schon kommon." The book is of fascinating interest and of practical value. There are forty-seven illustrations, six of which are colored plates.

Die Leberkrankheiten. By Dr. C. A. Ewald. Leipzig: Georg Thieme, 1913.

Professor Ewald's new book treats in a thorough manner of the diseases of the liver. In reference to functional disturbances of the liver, Ewald expresses himself as follows: "If finally we consider all methods offered by the functional diagnosis of the liver we must confess that the result, in spite of much hard work, is only small and that we possess a number of methods which keep us informed of the workings of the organ in general, but that none of them suffices to permit us to recognize with certainty any definite pathological condition." The author is of the opinion that cirrhosis of the liver is in the great majority of instances associated with an increase in the size of the organ (hypertrophic cirrhosis), and as far as the treatment of the ascites in cirrhosis is concerned the author considers abdominal puncture the sovereign means. He says: "Long ago (1885) I recommended the early and if necessary repeated punctures of the abdomen and showed that the loss of albumin is negligible, the effect on the blood-vessels, however, being most valuable for the local and general circulation. In one case I punctured 173 times, at first at 4 to 6 weekly intervals. The patient improved and finally left the hospital in fairly good condition. Since then I have practised early paracentesis wherever possible and have become one of its adherents in spite of warnings, to my mind unwarranted, against it." Almost at the same time Drummond and Morison, as well as Talma, proposed and executed the fixation of the omentum and possibly the spleen to the anterior abdominal wall for the purpose of establishing a collateral circulation. This procedure has, however, not proved as valuable as it would appear to be at first sight. The results have been varying, about 30 per cent. favorable. One of the most recent writers, Lieblein, had in fifteen cases only three marked successes and three fatal issues. The latter were particularly interesting from the fact that the operation showed that, although strong adhesions between omentum and abdominal wall already existed, a marked ascites had developed. The fact that the present volume has been written by one of the greatest clinicians, giving us the result of his vast personal experience, makes it of inestimable value. This is still further enhanced by the presence of numerous drawings, both in monotone and in colors, executed by Professor Ewald himself. The book can be recommended to every physician as one of the best and most valuable written on diseases of the liver.

The Care and Treatment of European Children in the Tropics. By G. Montagu Harston, M.D. (London), M.R.C.S. (London); Fellow of the Society of Tropical Medicine and Hygiene; Fellow of the Royal Society of Medicine; Member of the Ophthalmological Society of the United Kingdom; Ophthalmic Surgeon to the Tung Wa Hospital, Hong-Kong; and Examiner in Materia Medica and Therapeutics, Hong-Kong College of Medicine. With Introduction by Sir Patrick Manson, G.C.M.G., M.D., LL.D. Price $3.00 net. New York: William Wood & Company, 1913.

After discussing the climatic factors influencing European children in the tropics and the incidence of disease among these children, the writer points out the necessity of more painstaking care of the European child in the tropics and suggests certain modifications in hygiene. The body of the work is devoted to a description of the tropical diseases as they manifest themselves in children. While many physicians are familiar with tropical diseases in the adult, few have much knowledge of how they affect the child from the temperate zone, and hence the book opens up a new field for investigation. It contains many useful hints as regards the treatment of tropical diseases in children and is lucidly and simply written.

Die Exudativlymphatische Diathese. Eine Kurze Skizze für den Practischen Arzt. Von Privatdozent Dr. Paul Sittler. Colmar i. Els. früherem Dozenten für Kinderheilkunde an der Universität Marburg a. L. Price 3.50 marks. Würzburg: Curt Kabitzsch, 1913.

This interesting monograph details in a clear, sketchy manner the symptom complex of the exudative lymphatic diatheses, a picture which often remains unrecognized by the specialist and the general practitioner, and the individual symptoms of which are treated symptomatically without an understanding of their underlying association. To this group belong children suffering from chronic nasopharyngeal catarrh, Eustachian catarrh, and recurring otitis media, all of which are aberrations of a fundamental constitutional anomaly. The general picture of the exudative lumphatic diathesis, the special forms as they affect the various systems of organs, and the organs of special sense are discussed. The relation of this condition to the infectious diseases, the school, and social hygiene is dwelt upon.

The Internal Secretory Organs: Their Physiology and Pathology. By Prof. Dr. Artur Biedl, Vienna. With an introductory preface by Leonard Williams, M.D., M.R.C.P.; Physician to the French Hospital; Assistant Physician to the Metropolitan Hospital. Translated by Linda Forster. Price $6.00. New York: William Wood and Company, 1913.

The attention of many investigators in scientific medicine is turning at present from the study of parasitic diseases to those pathological conditions due to excessive or diminished secretion of certain of the so-called ductless glands, among them the thyroid, thymus, suprarenal, hypophysis, pineal, and generative glands. It has long been realized that some of the glands which pour out true secretions or excretions, such as the kidney, and pancreas, and the intestinal mucosa, may have as well internal secretions equally important to the animal economy. Our first knowledge of internal secretions is due to Thomas Addison, who described the clinical complex which bears his name and is connected with tuberculosis of the suprarenal gland. Addison's observations were completed upon a chemical and physiological basis by Oliver and Schaefer, who in 1894 announced that the intravenous injection of an extract of suprarenal was followed by specific and well-defined physiological results. Our knowledge of the thyroid secretion, though the problem has been attacked from many points by able investigators, is still incomplete, partly because of the complex chemical composition of the thyroid specific substance which has not yet been unraveled, and partly because of the many symptoms which accompany any functional alteration of this gland. An example may be found in the active discussion which is now going on as to whether exophthalmic goiter is due to an increased or a perverted secretion of the thyroid or to some entirely unknown lesion of the nervous system. The most complete statement of our present knowledge of such internal secretions is that which appeared some years ago from the pen of an accomplished German physician, and the medical profession owes a debt of gratitude to the publishers for having brought out this important volume in a very good and accurate English translation. After a general introduction, in which the history of the subject is developed and a classification of the various hormones is attempted, the special part, which occupies the larger portion of the book, begins with the thyroid, covering the anatomy, histology, and chemistry, the anatomy of the parathyroids and the physiology of these organs, the results of hypersecretion and atrophy, and thereapeutic results. Following this the thymus is considered, then the suprarenal system, then the hypophysis, to the knowledge of which our own Cushing has contributed so much. Then follows a short section on the pineal gland; and, finally, in the last one hundred pages, the internal secretions of the generative organs, the pancreas, the gastrointestinal mucosa, and the kidney are considered. A bibliography of 138 pages, down to 1911, is appended, though the author says that even this is not complete. Although the text of the German edition is now two years old there is very little of real importance in this phase of medicine which has been published since the book was issued, so that the volume as presented in this English form may be considered as the best study of the subject of internal secretions now in print.

Foods: Their Origin, Composition, and Manufacture. By William Tibbles, LL.D., M.D. (Hon. Causa), Chicago; L.R.C.P., Edinburgh; M.R.S.C., England; L.S.A., London; Medical Officer of Health; Fellow of the Royal Institute of Public Health, etc.; Author of "Food and Hygiene," "The Theory of Ions," etc. Price 18 shillings net. London: Baillière, Tindall & Cox; Chicago: The Chicago Medical Book Company, 1912.

The great revival of interest in the questions of human metabolism and the dietetic treatment of disease is revealed in the production of books of the nature of this on the composition, origin, and manufacture of foods. Part I treats of the chemical constituents of animal and vegetable foods from the point of view of the proximate principles. Part II treats of food products derived from animals—meats of all sorts, milk, cheese, butter, and oils. Part III of foods of vegetable origin; Part IV of condiments and spices; Part V of beverages. There is contained a large amount of valuable information not ordinarily accessible on the derivation and preparation of foods; for example, all of the various types of cheese are described, their methods of manufacture, as far as known, are outlined, and analyses showing their food value are given. It is interesting in an English book to note how frequently the reports of the Bureau of Animal Industry and other publications of the United States Government are referred to as authoritative. Minor defects can be pointed out, such as the omission of the Babcock method for testing fat in milk, the omission of analyses of special breads recommended in the treatment of diabetes for their diminished carbohydrate content, and the lack of recent references to subjects of considerable interest; for example, the toxic effect of methyl alcohol, the only reference to which is an article dated 1902. This subject has become of such great medicolegal importance that it is a pity the quite satisfactory abstract of the clinical symptoms is not complete. There is no mention of optic nerve atrophy which is a prominent symptom in wood alcohol poisoning, and the reader is not put in touch with recent publications on the subject. Except for such minor points as these, however, the volume is most excellent and contains much information of great use to physicians.

The Development of the Human Body. A Manual of Human Embryology. By J. Playfair McMurrich, A.M., Ph.D., LL.D., Professor of Anatomy in the University of Toronto; formerly Professor of Anatomy in the University of Michigan. Fourth Edition, Revised and Enlarged. With 285 Illustrations, several of which are printed in colors. Price $2.50 net. Philadelphia: P. Blakiston's Son & Co., 1913.

This convenient little handbook of embryology now appears in its fourth edition, an evidence of its value to the student-body. It is well illustrated, well printed, and well bound, and within its limitations of space remains one of the best of the smaller texts on embryology.

Formulaire des Consultations Médicales et Chirurgicales. By G. Lemoine, Professor of Clinical Medicine, and E. Gérard, Professor of Pharmacy and Pharmacology. Faculty of Medicine and Pharmacy of Lille. Sixth Edition. Price 8 francs. Paris: Vigot Frères, 1913.

This book is divided into two parts. The first is a complete materia medica with preparations, use, and dosage of various drugs of the pharmacopeia. The second part consists of medical consultations in which each disease is discussed with symptoms and complications, together with therapeutic measures for its relief or cure. The book seems likely to be useful.

# Society Reports.

## AMERICAN MEDICAL ASSOCIATION.

*Sixty-Fourth Annual Meeting, Held at Minneapolis, Minn., June 16, 17, 18, 19 and 20, 1913.*

(Special Report to the MEDICAL RECORD.)

(*Continued from page 1149.*)

### HOUSE OF DELEGATES

*Wednesday, June 18.—Second Day.*

**A Speaker for the House.**—A special meeting was called to consider the resolution presented on the previous day providing for the appointment of a speaker for the House to relieve the president of more arduous duties and to permit the executive to give his time to formulating the policy of the organization and presiding only at the more important meetings. After a lengthy debate the House decided that it was not advisable or necessary to have such a speaker at the present time.

**Special Committee on National Board of Health Dissolved.**—This committee, which was appointed at the meeting in St. Louis in 1910, in its report to the House entered complaint because it was not given sufficient money to carry on its work. A discussion of the work of this committee ensued and finally the committee, consisting of Drs. William C. Woodward of Washington, H. M. Biggs of New York, H. P. Walcott of Cambridge, Mass., J. N. Hurty of Indianapolis, J. N. McCormack of Bowling Green, Ky., W. A. Evans of Chicago, S. G. Dixon of Harrisburg, Pa., and W. H. Welch of Baltimore, was dissolved. The reason given for this action was that the work of the committee conflicted with that of the Council on Health and Public Instruction and that this council would carry on the work of prosecuting a campaign for a National Health Department.

*Thursday, June 19.—Third Day.*

**Associate Members.**—SAMUEL HOPKINSON ADAMS was elected an associate member of the association and was granted the privilege of the floor. After acknowledging the honor conferred upon him he declared that in fighting the advertising quack the medical profession had been making the mistake of aiming at the inside of the bottle, at the medicine, instead of the outside of the bottle, the label; quack remedies were one-tenth medicine and nine-tenths advertisement. They must sell through the newspapers. Through the work of vigilance committees the newspapers no longer accepted fraudulent advertisements. Many had voluntarily cleansed their columns and others were on the verge of decision. The papers did not like these advertisements.

**Supplementary Report of Board of Trustees.**—Dr. W. W. GRANT of Denver said that the Board of Trustees wished to call attention to the offer of the home for the widows and orphans of physicians and recommended that the matter be considered by the Judicial Council. They wished to authorize an appropriation for preliminary work in the coming commemoration of the opening of the Panama Canal and they recommended that the present committee be continued or a new one appointed to take charge of the preliminary work. They further recommended that the commemoration take the form of a Congress on Tropical Medicine and that a permanent movement be provided for by popular subscription in commemoration of American Preventive Medicine and Sanitary Science. In this project they recommended that the cooperation of the Association of American Engineers be invited and that Congress be petitioned for permission to erect such a monument and invited to appropriate a suitable site.

**A New Section.**—The resolution providing for a new section to be known as the Section on Gastroenteroproctology was adopted by the House.

**Supplementary Report of the Judicial Council.**—Dr. ALEXANDER LAMBERT of New York said that the matter of the application of the medical societies of Porto Rico for affiliation with the American Medical Association had been considered and the status of the medical societies of Porto Rico investigated and the Judicial Council recommended them for membership in the American Medical Association. This recommendation was adopted.

**An Advertising Bureau for State Journals.**—Dr. C. R. WOODSON of St. Joseph, Mo., presented a resolution to the effect that as the State journals were dependent upon advertising material for financial help and that as there was a tendency among independent journals to make combinations in order to aid their advertising departments, and as the State journals must have some help, it would be advisable to inaugurate an advertising bureau for the benefit of those journals. The resolutions also provided for an appropriation sufficient to establish such a bureau on a working basis. This resolution was adopted by the House.

**Congratulatory Resolutions for Newspaper.**—Dr. A. T. MCCORMACK of Bowling Green presented resolutions endorsing the stand that the Minneapolis *Journal* had taken with reference to the exclusion of advertisements of quackery and congratulating the paper for having proved that a newspaper could be conducted successfully without accepting such advertisements. A resolution was also adopted endorsing the Printers Ink bill.

**Election of Officers.**—The following officers were elected for the year 1913: *President*, Dr. Victor C. Vaughan of Ann Arbor, Mich.; *First Vice-President*, Dr. Walt P. Conaway of Atlantic City, N. J.; *Second Vice-President*, Dr. Frank C. Todd of Minneapolis, Minn.; *Third Vice-President*, Dr. Lillian H. South of Bowling Green, Ky.; *Fourth Vice-President*, Dr. S. G. Kahn of Salt Lake City, Utah; *Secretary*, Dr. Alexander Craig of Chicago, Ill.; *Treasurer*, Dr. William Allen Pusey of Chicago, Ill.; *Trustees*, Dr. W. W. Grant of Denver to succeed himself, Dr. Frank J. Lutz of St. Louis to succeed himself, Dr. Oscar Dowling of Shreveport, La., to succeed Dr. C. E. Cantrell of Greenville, Texas, and Dr. Thomas McDavitt of St. Paul to succeed C. H. Dougherty, deceased; *Member of Judicial Council*, Dr. A. B. Cooke of Nashville, Tenn.; *Member of Council on Health and Public Instruction*, Dr. W. S. Rankin of Raleigh, N. C.; *Member of Council on Medical Education*, to fill Dr. Victor C. Vaughan's place, Dr. H. D. Arnold of Boston, Mass.

**Place of Meeting.**—Atlantic City was chosen as the place of meeting in 1914.

**Awards on Scientific Exhibit.**—The committee on awards reported that they wished to commend the exhibit as a whole. The gold medal had been awarded to Dr. C. C. Bass of Tulane University for research work in malaria. Among those receiving honorable mention were Drs. Erwin Smith, L. B. Wilson, W. D. Gatch, J. S. Horsley, and R. D. Carmen.

### SECTION ON DISEASES OF CHILDREN

*Tuesday, June 17—First Day.*

DR. HENRY DWIGHT CHAPIN OF NEW YORK IN THE CHAIR.

**Rupture of Mediastinal Lymph Node into Bronchus.**—Dr. A. L. GOODMAN of New York described a case showing practically no symptoms until the sudden onset of the acute condition, which required almost instant surgical intervention. He thought the cases were properly divided into two classes, tuberculous and non-tuberculous, and that the non-tuberculous were due to streptococcic, or staphylococcic infection or a mixture of the two. He said that prognosis depended upon whether the node remained small or went on to suppuration or perforation. He considered that where medical treatment could be used it would be practically that used for incipient tuberculosis and guaiacol and arsenic given for a period of a year or more, but where the condition was sudden in onset and violent, surgery should be resorted to at once.

Dr. WILLY MEYER of New York said that the case reported had been his and that he considered the prompt surgical intervention the means of saving the patient's life. Such conditions were not rare in adult practice and he cited the case of a young woman of his practice who was brought to the hospital following a slight accident from an automobile and developed a cough and symptoms of lobular pneumonia and thoracic trouble, probably tuberculous. From the *x*-ray picture it was determined that she had a cold abscess which had perforated into the bronchial tree. He thought that in such cases, unless there was immediate outlet for the mass, the condition proved fatal.

Dr. ISAAC ABT of Chicago said that from the studies of men who had seen thousands of cases it had been determined that tuberculous infection through the bronchial glands was extremely common and that the rapid strides made in the handling of these cases made treatment of them fairly satisfactory, but such results as Dr. Goodman had had were brilliant and noteworthy.

Dr. ALBERT WILLIAM MEYERS of Milwaukee brought out the use of the bronchoscope in the diagnosis of such cases as a supplemental aid.

Dr. C. F. WAHRER of Fort Madison, Ia., wished to know what other infection was found in these conditions besides the tuberculous.

Dr. Goodman, in closing the discussion, said that in the majority of cases the tubercle bacillus was the exciting cause, though in the case reported, after working eight months, he had not been able to demonstrate its presence. He thought the previous literature justified him in classing the cases as tuberculous and non-tuberculous and the non-tuberculous as due to streptococcic, staphylococcic, or mixed infection. He thought the bronchoscope impractical because of the sudden onset of the cases. Possibly in the future where large masses of lymph nodes were found the Sauerbruch chamber would be indicated.

**Report of a Case of Staphylococcus Meningitis in a Child.**—Dr. Frank Spooner Churchill of Chicago read the report of a case in a 21-months-old child with history given by the mother pointing to intestinal rather than meningeal symptoms. The only meningeal symptoms were slight rigidity of the neck and drowsiness. Lumbar puncture showed the presence of staphylococci. Two more lumbar punctures were made and from the last an autogenous vaccine was prepared, after a single injection of which the temperature immediately became normal and the child made an uneventful recovery with no relapse after four years. He called attention to the fact that no conclusions could be drawn from the single case but he wished to report it, hoping others would try similar treatment in like cases.

Dr. H. Lowenburg of Philadelphia said that in a case of lobar pneumonia that developed streptococcic synovitis in which he used a stock vaccine there was a marked reduction of temperature for about three days. He said that his patient was extremely emaciated and died following the operation, but he thought the vaccine had a marked influence in reducing the temperature.

Dr. G. P. Gencepach of Denver said that he thought if the skin was well washed and if the site of the puncture was touched with tincture of iodine there was practically no danger of contamination. He called attention to the necessity of avoiding deep puncture so as not to enter the blood stream.

Dr. Churchill thought there must be some therapeutic advantage in repeated lumbar puncture and regretted that in his case it had not been done oftener. He used a stock vaccine until he could obtain the autogenous, but had made no comparative studies between the two. He did not believe contamination from the skin was likely if ordinary asepsis was practised. He urged practitioners to perfect their technique of lumbar puncture.

*Wednesday, June 18—Second Day.*

**Acute Acid Intoxication in Children.**—Dr. Thomas C. McCleave of Berkeley, Cal., in reading this paper called attention to the prevalence of a fairly definite symptom complex, in which acidosis was a constant factor, occurring in children of from two to ten years. He thought that the clear clinical picture presented made a differential diagnosis fairly easy, but called attention to the obscurity of the etiological factors and the fact that because so few cases resulted fatally, there were few confirmatory data obtainable through autopsy. He had determined from his experience that while the attacks were always due to intestinal toxemia, nervous conditions were a large element and no other single remedial measure so important as attention to the throat. He called attention to the fact that when children suffered from repeated attacks there was sure to be some degree of toxin absorption which acted upon the liver and by nervous, vasomotor or other disturbance precipitated the attack. This being the case, he said, they offered excellent opportunity for satisfactory therapy through the removal of causative factors, the regulation of diet and hygiene and the periodical administration of alkalies. He said that as the condition was more common than was generally supposed it was necessary that physicians should be familiar with it.

Dr. J. Zahorsky of St. Louis took exception to the descriptive term "dusky" as applied to the appearance of the faces of these patients. He said his were almost uniformly mottled and flushed. He thought that one thing would often prove of diagnostic value. He reported a case in his practice that had entirely cleared up after circumcision and thought this pointed rather to the fact that any slight operation would be of benefit in the condition because of its result upon the nervous organism of the child rather than that the removal of adenoids, tonsils, or appendix was curative. He considered the disease directly related to migraine because his cases usually presented in families showing general metabolic disturbances. He urged physicians to pay particular attention to the liver because his cases all showed enlargement readily discernible by palpation.

Dr. J. Ross Snyder of Birmingham, Ala., called attention to Dr. Parks' classification several years ago of enlarged liver as part of the symptom-complex. He said that in the South where the condition was particularly common it was seen in children much younger than the age limits given in the paper—occurring most commonly between the eighth and eighteenth month. He thought that fully 80 per cent. of this type of cases resulted fatally.

Dr. C. H. Johnson of Grand Rapids, Mich., thought that the condition was too often confused with gastro-intestinal troubles and that little attention had been given to it in the literature. He considered diseased tonsils a large factor because in his own son the complete enucleation of the tonsils had cleared up the condition, and all of his cases had begun with throat disturbance. Medicinally he had used morphine hypodermically to control the vomiting and credited it with saving some of his cases from a fatal termination.

Dr. G. D. Ryan of Des Moines reported that his son had had repeated attacks of vomiting of acid origin and had responded well to 5 per cent. solution of bicarbonate of sodium administered by the drop method.

Dr. Thomas B. Cooley of Detroit thought that cases of acidosis should be distinguished from recurrent vomiting. He said that all he had seen seemed to be accompanied by acute infection, usually of the influenzal type, and that prostration was very great from the start, with low temperature and great air hunger. His cases did not show as severe vomiting, nor was this so hard to check as in cases of recurrent vomiting where there was a strong nervous element. His patients were very sick and sometimes died in twelve hours after the onset of the disease.

Dr. Isaac A. Abt of Chicago called attention to the necessity for a more general and careful study of acid conditions of the urine. He said that many infants, particularly at the weaning period, suffered from gastrointestinal disturbances, such as slight diarrhea, rapid pulse, moderate fever, very rapid breathing and soon after great prostration and constipation even to complete obstruction of the bowel and had been classified under the general head of gastrointestinal disturbance. More careful study would show these to be suffering from acidosis. He concluded from his experience that some toxic protein was responsible for this almost uniformly fatal type of toxemia.

Dr. John Lovett Morse of Boston said that he had had many cases which he was sure were due to acid intoxication, because even the parents had been able to detect the odor of acetone in the urine. His experience had been that many other things were being called acid intoxication rather than that this condition was being overlooked. He laid this to the fact that a little acetone had been found in the urine, and the condition had been ascribed to that without further consideration of the findings. He said that acetone or diacetic acid gave symptoms only when present in considerable quantity.

Dr. H. T. Price of Pittsburgh thought it hardly likely that the nervous system had much to do with the condition, as children allowed to continue living in the same environment recovered when other conditions were attended to.

Dr. L. R. de Buys of New Orleans thought that when physicians generally recognized the gravity of the disorder, which previous literature had not emphasized, it would be more carefully studied and promptly met. His cases showed facial flushing almost resembling that of scarlatina, and as the condition improved it gradually disappeared. He had noticed that the temperature, at first high, fell promptly with the cleaning out of the alimentary canal. If it did not come down, he said, it indicated that the elimination of toxins was checked.

Dr. H. Lowenburg of Philadelphia cited a case in a child of four in which examination of the urine showed no evidence of intoxication, although the diagnosis of acidosis had been made. *X*-ray revealed a marked degree of pyloric spasm. The child recovered with two stomach washings and had not had a recurrence in five months. In another case in his practice the child had been sent to him with a diagnosis of recurrent vomiting. In this case the *x*-ray revealed a kink in the bowel in the region of the sigmoid. The child had been very constipated. This case recovered with high enemas of olive oil. He had used bicarbonate of sodium and Fisher's solution under the skin, and in each case had had sloughing of the skin—to such an extent in one case that he had contemplated skin grafting. Since that time he had been using it by the so-called Murphy treatment and found that his patients bore it well, and with care the catheter could be retained and the same results obtained.

Dr. McCLEAVE in closing the discussion accepted the correction of Dr. Zahorsky as to the flushing of the face, but said that he had intended to convey the picture of the bluish-pallid ring under the eyes, the whiteness around the lips, and the flushing of the cheeks so characteristic of the disorder. He again emphasized the points regarding the diseased tonsils and appendix and the presence of adenoids as sources of the toxin and said that the liver being so susceptible to toxins it showed their presence first, and that with their removal in his experience the liver symptoms had cleared up. He thought that the symptom-complex appearing in very young children was entirely different than that under discussion and had not considered them. He considered some of the neglect of the subject by the profession to be due to the fact that in the West the condition had not been as common as in the South and East, and therefore was confused with other gastrointestinal disorders.

**The Protein Poison and Its Relation to Disease.**—Dr. VICTOR C. VAUGHAN of Ann Arbor said that from his experiments all proteins, both particulate and formless, both cellular and in solution, had been found to contain a poisonous group, although just what the chemical condition of the poison was he was not prepared to state. It was, however, a very real and active poison, as had been shown when it killed the experimental guinea pigs. He said that when, for any reasons, proteins taken into the alimentary canal escaped digestion and were absorbed unchanged they underwent parenteric digestion, and in that process the poison was set free. He said that in enteric digestion the poison was most marked in its action at or about the peptone stage; that when digestion was normal and proceeded beyond that stage the poison was destroyed by further cleavage. He said that as the intestines of children were more permeable to proteins than those of adults, children suffered more generally from gastrointestinal disturbances, and because of the more rapid absorption from the intestines during the summer time, incompletely digested proteins were taken into the system. From this he concluded that even if it were possible to get absolutely clean milk summer disorders in young children would not markedly disappear, and even suggested that the presence of bacteria might be an advantage as they split up the milk and made it more readily digestible. From his work he had determined that when the proteins were broken up by the parenteric digestion the poison was set free in the blood and tissues and manifested its full effect.

Dr. J. ZAHORSKY of St. Louis said that since it had been generally recognized by American physicians that there were certain summer diarrheas that were not due to bacteria it was beginning to be supposed that their exciting cause would be found in the protein, especially in those cases that could not be cured by changing the food for a day or two.

Dr. MARY STRONG of Omaha said that in her clinical work she had seen evidences of what Dr. Vaughan had demonstrated in the laboratory to be the results of absorption of protein through the intestines caused by heat and advocated strongly looser, cooler dressing of infants to prevent summer diarrheas.

Dr. C. H. JOHNSON of Detroit said that if these ideas and those of Finkelstein could be put together there would probably be a working hypothesis, as Finkelstein had reduced the mortality in his institution from about 80 to 6 or 7 per cent.

Dr. CLIFFORD G. GRULEE of Chicago said that the prime factor of this theory was that the protein must be absorbed through a deranged gut. He called attention to the work of Benedicks and Samuelson as showing by the subcutaneous injection of sugar solutions made of fresh distilled water and old distilled water that no ill effects were caused by the former while the latter gave a prompt rise of temperature, and that the same results had been produced with the salt, which would seem to contradict some of the views held by Finkelstein. He thought it very probable that the intestinal mucus was a source of putrefaction.

Dr. LOUIS BURCKHARDT of Indianapolis said that although the milk supply in their city had been greatly improved since the inauguration of the Milk Commission, still the summer diarrheas were not markedly decreased and the municipal authorities were considering compulsory pasteurization, and wished to know Dr. Vaughan's views as to this measure.

Dr. HENRY W. CHENEY of Chicago wished to know if the protein poison was not the same as was present in the horse serum that caused anaphylaxis and death.

Dr. GEORGE S. CATTERMOLE of Boulder, Col., said that in their climate there was little summer diarrhea, which gave weight to the theory of increased absorption of proteins by the intestines because of heat.

Dr. THOMAS C. McCLEAVE of Chicago wished to know why if the protein poisoning was the same in all conditions, and the symptomatology depended merely upon its location all exanthematous diseases showed the specific infection through the skin.

Dr. VAUGHAN in closing the discussion said that the other constituents of the food, organic and inorganic influence, played their relative parts in the absorption through the intestines. He said that the exanthems resulted when the infections were deposited in the skin. From the work done so far he had concluded that when proteins were taken into the blood stream they had a predilection for a definite location, but wished to do more work before saying positively that this was a fact. He thought compulsory pasteurization would have little effect in eliminating summer diarrheas.

**The Nature of Ileocolitis from an Etiological Standpoint.**—Dr. CLIFFORD G. GRULEE of Chicago, in presenting the subject said that the term, originally pathological, had become clinical and conveyed to the physician a patient suffering from bacterial infections, decomposition of foods by intestinal bacteria, and metabolic disturbance. He said that just what part heat played in the disorder was at present unknown, but thought that absorption of the mucus should be taken into consideration. He fed his patients curds of skim milk in gelatin water and had not had anything like the protein fevers that Holt and his confreres had reported.

Dr. R. M. SMITH of Boston said that from the large amount of Kendall's work that he had seen and from his own experience he was not sure that bacteria had no part in the etiology, especially so as different forms responded to different treatments, as would be expected from a disorder of bacterial origin.

Dr. E. W. MITCHELL of Cincinnati said the fat-free diet in all intestinal disturbances was the best treatment.

Dr. JOHN LOVETT MORSE of Boston thought it impossible to draw definite conclusions while the studies were in the transitional stage, but inclined to the theory of bacterial origin.

Dr. GRULEE in closing the discussion did not wish to be understood as saying that bacteria played no part in summer diarrheas, but did say that he did not believe the specific bacteria played an important part, as they had not been proven to be especially pathogenic. He thought it would be extremely difficult to get clinicians to agree unless they could see the same sets of cases, as environment and individual treatment so largely affected the course of the disease.

**Nutritional Injuries Produced by Starch.**—Dr. ISAAC A. ABT of Chicago pointed out that the principal injuries were in young infants who were given starch without milk for a long period of time, probably arising from actual food deprivation. Because of this feeding the resistance to infection was lowered and if the condition of inanition was continued loss of function was inevitable, and eye troubles were a common symptom of this condition. He thought the atrophic form most amenable to treatment. He reported several cases from his practice that had done well following the administration of breast milk where possible, or modified cows' milk, but urged the giving of small quantities, even as little as two ounces at a time, at frequent intervals, until the severe symptoms had subsided. He said that he continued to use breast milk until the child began to gain in weight, when even a top milk diet could be used if the infant's tolerance to fats was not overreached.

Dr. J. ZAHORSKY of St. Louis said that many physicians prescribed an oatmeal diet in these conditions, but as it lowered the resistance he did not think it good practice. In one case that he returned to breast milk he did not have good results, but attributed this to giving too much at a feeding because in another case with almost identical symptoms, in which the infant was fed only a little at a time, he had good results.

Dr. G. P. GENGENBACH of Denver reported the case of an infant of seven months coming to him from the practice of another physician. The infant had been placed on barley water and during an illness of the attending physician was permitted to remain on it until nephritis developed, with the presence of edema over the entire body. He put it on a one-third milk modification and it made a prompt recovery.

Dr. FREDERICK W. SCHULTZ of Minneapolis reported a case coming to him that had been fed almost entirely on oatmeal and barley water, having marked edematous symptoms and rigid muscles. He put it on small quantities of breast milk with beneficial results.

Dr. Julius H. Hess of Chicago thought that probably many deaths due to this disorder were attributed to other conditions and deplored the common practice of telling mothers to put babies having diarrhea on barley water. He said that while they usually did not continue this for a very long time, the cereal decoction would gradually weaken the infant's resistance until the secondary infection was noticed and the prompt succumbing of the patient.

Dr. L. D. Buckley of New York described fully the preparation of a wheat jelly that he had used very extensively in his practice with remarkably good results and thought it the ideal food because it gave all of the starch, some of the nitrogen, and an extract of the phosphates in the wheat.

**Status Thymicolymphaticus with Report of Four Cases in One Family.**—Dr. Walter L. Bierring, Dr. G. L. Golmset, and Dr. J. A. Goodrich of Des Moines, Iowa, presented this paper, which was read by Dr. Bierring. He gave the clinical report of four cases occurring in patients, all of one family, ranging in age from two to seven years, the deaths all taking place between April 8 and July 12, 1912. An autopsy was held in each instance and each revealed practically the same condition. The special clinical-pathological features he reported were previous good health, preliminary warning deafness, thymic asthma, more or less sudden death, hyperplasia of the thymus, and enlargement of the lymph nodes. He thought that the pathological physiology of the thymus presented the only point of possible solution of the nature of the disease. The treatment instituted was largely symptomatic, tending toward reduction and depletion of the thymus structure. He thought that operation, while attended by grave risks was still satisfactory but considered that radium and the *x*-ray produced the most marked reduction in the thymus, spleen, and lymph structures. He called attention to the reactive process and suggested the selective nature of the disease as indicating a definite exciting cause.

Dr. Clifford G. Grulee of Chicago wished to know if there were well-defined symptoms of rickets.

Dr. C. F. Wahrer of Ft. Madison, Iowa, thought that the fact of there being four cases in one family pointed to heredity and suggested that this was a point to be considered in eugenics, especially as nothing definitely curative could be done.

Dr. Mary Strong of Omaha asked whether a Wassermann was made and potassium iodide used.

Dr. J. Zahorsky of St. Louis wished to know what, if any, effect the giving of antitoxin had had.

Dr. Bierring, in closing the discussion, said that the patients were all pot-bellied and all had suggestive symptoms of rickets. He said that careful study of the literature failed to emphasize heredity in any group of cases, but in the father's family the report of nine children all dying before the ninth year was suggestive, but he was unable to get any definite information as to the causes of the deaths. He regretted that it was impossible to get a Wassermann, but said that he did use the iodides without any apparent results. He said that the antitoxin had been given in the spring of 1911 and the deaths did not occur until the summer of 1912, so he did not attribute the condition in any way to the antitoxin, although he said the patient that had had diphtheria never seemed to entirely regain strength.

**Treatment of Hemorrhagic Conditions in Infancy and Childhood.**—Dr. Thomas B. Cooley of Detroit said that temporary or permanent lack of some one or more elements of the blood was probably the cause of the inability to clot, there being probably different elements in different cases, although calcium had not been proved to be lacking in any case. He said that so generally was this the accepted theory that almost the only treatment now being used was that which supplied the lacking elements to the blood. He had used human serum, horse serum, and whole blood with good results, but said that in melena his results had not been as good as Clow's, probably because he had not used enough. He said that surprisingly little had been written on the use of human blood, but he thought it scarcely reasonable to suppose that the small amount injected supplied all of the lacking elements in the blood and rather leaned to the idea that the injected reacted as a stimulant to the patient's blood. He urged more frequent use of transfusion in these cases, and the use of it early in the treatment rather than as a last resort. He said that since the simpler technique had been worked out this could be used by almost anyone and as it supplied all of the elements of the blood it was the most surely beneficial. He had found the amount really necessary to be injected quite small and it was deserving of trial in any of the hemorrhagic diseases of a toxic nature.

Dr. V. D. Lepinasse of Chicago said that of ten cases treated he had lost two and both were complicated with syphilis. He said that cases that were almost dead could be saved if transfusion was used. He continued to inject blood until the patient became red, but warned against injecting too rapidly on account of the anemic condition of the heart. He said that in his cases the hemorrhage stopped at once and did not recur except in the syphilitic patients.

Dr. H. M. McClanahan of Omaha made a plea for the doctors in small towns and rural districts who had not access to modern facilities. He said to such he had been recommending the use of antidiphtheritic serum as the next best thing, and in one case blood had been injected into the bowel and gave positive curative results.

Dr. Julius H. Hess of Chicago said that the rapid development of the use of this measure called for a rewriting of the literature and wished to know if anyone had given repeated injections of horse serum over a period without anaphylaxis.

Dr. Ogden M. Edwards of Pittsburgh thought that no positive treatment could be outlined until the proper etiology was discovered. He thought that infection, association with syphilitic conditions in the mother before birth might all have their effects and if so would modify treatment.

Dr. H. Lowenburg of Philadelphia reported the case of a boy who, after biting his tongue, bled for two days and was brought in for treatment. He responded promptly to two injections of horse serum given at seven in the evening and ten o'clock the following morning, but he did not consider this a permanent cure because following an injury to the hip received five months later the injury was five or six weeks in healing.

Dr. C. Brooks of Pittsburgh presented a needle which he and Dr. Edwards used with very good results in their practice. It was connected with a Y-shaped rubber tube so that the blood could be taken from the donor and injected into the patient without interruption. He emphasized the need for the simplest possible method of transfusion.

Dr. Cooley in closing said that in the case reported the child was practically dead when the treatment was started and 20 c.c. of blood, alternated with injections of salt solution, were given. He said that they did not continue until the child became red, but stopped as soon as there was improvement and the pulse became stronger. He thought that where salt solution was alternated with the blood injections the danger of going too rapidly was overcome. He considered the condition due to some sort of toxemia, usually infectious, although not always.

**Treatment of Inguinal Hernia in Children.**—Dr. Arthur E. Hertzler of Kansas City, Mo., advanced the idea that all hernias were congenital and said that he did not believe that any hernia was ever cured by a truss and advocated operation at once as the presence of the hernia was a constant hindrance to the activity of the child and sometimes even a menace to life. He said that no reports of cure by wearing a truss could be accredited until at least twenty-five years had elapsed as the hernia was apt to reappear at any time. He said that so far as his experience went the only patients who had not progressed satisfactorily were those allowed to go home immediately after the operation where the dressings had become soiled and infection had resulted.

Dr. C. G. Buford of Chicago said that the treatment of hernias in children and in infants was entirely different, that in infants it was practically impossible to put on a dressing that would not get soiled and endanger the patient through infection. He thought that many cases of hernia in very young children were not congenital but acquired. He deplored the advising of operation for anything that could possibly be either treated or tided over in young infants because of their extreme liability to infection. He said that the only hernias that should be operated upon were those in which for some reason or another the baby could not wear a truss, or the parents insisted upon an operation, or where the hernia came out in spite of the truss. He said that if physicians would take pains in adjusting the truss, would superintend its adjustment themselves, there would be found few patients who could not wear them satisfactorily. His experiences indicated that the hard rubber truss, with a pad to suit the individual needs of each patient, kept strictly clean and properly placed could be worn comfortably and without hampering the movements of the child.

**General Anesthesia in Surgery of Childhood.**—Dr. William Cavan Woolsey of Brooklyn read this paper and after sketching briefly the physiological and patholog-

ical considerations in the surgery of childhood in their relation to anesthesia said that errors of technique arising from inexperience, carelessness, and a disposition to sacrifice the well being of the child to the convenience of the operator were responsible for the high morbidity in pediatric surgery, especially in adenoid and tonsil work. He exhibited a simple apparatus for the giving of nitrous oxide and ether which he had used most successfully.

**Spasmophilia with Especial Reference to Familial Reactions.**—Dr. Julius Parker Sedgwick of Minneapolis exhibited a chart showing in the cases reported the electrical reaction of the mother or some member of the family seeming to point to a familial or hereditary origin. He said that in cases of general convulsions, tetany, laryngospasm, spasmodic apnea and other closely allied conditions new light could be thrown upon the subject through the study of the electrical reactions. He said that the cases he had seen seemed to bear no relation to epilepsy, and were short in duration, but that the course of the disease was tedious, lasting seven or eight years and that the cases of "repeated absences" usually cleared up at puberty. He thought there was little field for medicine in these cases, although the bromides might be used if necessary. He eliminated cow's milk from the diet of his patients and substituted carbohydrates.

Dr. A. C. Rogers of Faribault, Minn., wished to know what percentage of cases showed a familial reaction.

Dr. Mary Strong of Omaha asked whether any had been examined by psychiatrists to determine their mental condition.

Dr. J. Zahorsky of St. Louis pointed out that in the cases in infancy there would be difficulty in withdrawing the milk for a very long period, although it could be withdrawn for a short time and then given in small quantities gradually as the system would tolerate it.

Dr. Sedgwick in closing the discussion said that in fully 75 per cent. of the cases where he had an opportunity to examine other members of the family he got reactions. He reported that some of his cases did show mental deficiencies. The literature gave the number as 30 per cent., and he had accepted it because he thought it represented his series fairly well. He said that his experience showed that the infants could be returned to cow's milk in a very short time and tolerated it very well with a little guarding against overfeeding. In older children he had resorted to a vegetable diet with good results.

**Desirability of Early Diagnosis of Mental Deficiency.**—Dr. A. C. Rogers of Faribault, Minn., emphasized the need of attention to suspected defectives so that all those recognized as in any way abnormal could be examined by the school physicians and psychologists and proper steps taken in each case. If, after physical impediments were removed or corrected, there was still retardation he thought that the measure of the child's intelligence should be taken so that he might have the best training possible to make him a self-supporting citizen. He recited many cases in institutions of children with very little mental development who, by study with the Binet tests, had been classified as to their mental capacities and their lives and occupations regulated accordingly and from the satisfactory results obtained by the present system, urged physicians to make more general use of this in their practices for their own information, for the guidance of parents in the management of the child, and for the benefit of the child, so that the latter might not be forced beyond his mental attainments.

Dr. Mary Strong of Omaha brought out the influence of alcoholism in such conditions, the necessity of confinement of such cases, and the regulation of marriage laws so that such subjects might not propagate their kind.

Dr. A. C. Rogers in closing said that at present the wisest course seemed to be segregation into colonies, but as the number increased this would not be practical, and it would undoubtedly be necessary to teach their proper care in the homes. He thought that sterilization had a very limited application.

*Thursday, June 19—Third Day.*

**Election of Officers.**—The following officers were elected for the ensuing year: *Chairman*, Frank Spooner Churchill, of Chicago; *Vice-Chairman*, Dr. L. R. DeBuys, of New Orleans, La.; *Secretary*, Dr. G. P. Gengenbach, Denver, Colo.

**Vulvovaginitis in Children.**—Dr. Richard M. Smith of Boston emphasized particularly the frequency of the condition, and its social aspects. He said that with the cooperation of the social settlement worker it was not often difficult to get the source of the infection and when that was determined and the avenue shut off the condition could be cleared up. He considered the medical treatment but a small part of the work. He said that parents should be educated as to the grave dangers of the disorder and the extreme liability of contagion, so that when it appeared in the family others could be protected against it. He considered the complement-fixation test the best aid to diagnosis and said that since diagnosis had been more accurate and the general gravity of the condition generally accepted it was less common in epidemic form than formerly. He thought that the pessimism of reporters was not justified by facts as he had had excellent results from douches and the silver salts. He urged the employment even in pediatric wards of a competent genitourinary surgeon for the acute cases. He thought any case that after a period of a year or more showed total absence of the discharge and a negative complement-fixation test might properly be termed cured, but emphasized the need for closing the source of infection or there would be prompt reinfection.

Dr. Frank C. Neff of Kansas City, Mo., thought that out-patients in poor districts, under poor conditions of sanitation and hygiene, presented a very unfavorable outlook. His experience showed that it was impossible to give them enough local treatments to be of much benefit. He had seen no good results accrue from the use of either autogenous or stock vaccines. He thought there were few cases in which it could be definitely said there would not be a recurrence of symptoms within a year. He thought that management of the child at birth was most important.

Dr. H. M. McClanahan of Omaha thought the cases hopeless unless they could be followed up, and considered this the most forceful argument for the social settlement worker. He brought out the fact that these infections in childhood might account for some of the sterilities in women.

Dr. H. Lowenburg of Philadelphia did not agree with the prognosis given in the paper. He said that cases presented in the Philadelphia General Hospital had been treated with various silver salts, permanganate and even sour milk (under the theory that the lactic acid bacillus prevented the growth of gonococcus) but during a period of five years practically all had shown recurrence. He thought the effect of the treatment mechanical, therefore not permanent. He called attention to the need of prevention and education to remove the source of the infection.

Dr. D. L. Richardson of Providence, R. I., thought the best results were obtained by cooperation between the social worker and the hospital and said that while the cases were active the hospital was their proper place. He said that in their hospital any suspected case, whether it gave positive reaction or not, was isolated. He thought any case could be isolated and no hospital epidemics would occur if nurses were careful in asepsis.

Dr. Julius H. Hess of Chicago wished to know if the applications of silver were vulvar or vaginal or both.

Dr. M. L. Turner of Des Moines said that if a gonococcus was present irritation to the vagina would make it active and if a case, after treatment, did not show activity with such irritation he thought it might be termed cured and a recurrence laid to reinfection.

Dr. C. F. Wahrer of Fort Madison, Ia., reported unmistakable cases of vulvovaginitis in children of from one to five years and urged physicians to try to educate the parents to these conditions and the need for proper watching and care of their children. He reported good results with cases that he had been able to keep under his supervision. His treatment consisted of persistent treatment with silver, and local treatment with bougies, but did not believe much could be expected from serum and globulins in acute cases, although they might do good in chronic cases.

Dr. J. Zahorsky of St. Louis thought that in private practice the cases recovered more promptly than in hospital because a child confined in a hospital always had his resistance lowered. He believed there was a local and general immunity established in a child living under good hygienic conditions that could not be set up in a child in hospital environment. He expressed the hope that there would still be a serum made that would assist this immunity.

Dr. Henry Dwight Chapin of New York said that in their hospital a smear was taken of each child as it entered, but that they had been considerably puzzled by the fact that many children after being in the hospital got up a discharge, afterward found to be gonococcal, that they did not have when they came. He thought possibly it was a latent germ that became active in hospital environment. He said that every precaution should be taken to prevent its spread throughout hospital wards and described in de-

tail their method of sterilization which had been tried and found inadequate to such an extent that at present they were using individual gauze dressings for each patient which were placed in paper bags after using and burned He said that, while more expensive than napkins, it seemed to be the only method that would prevent the spread and that no expense or trouble should be too great to prevent even one case. He had seen but one case in which the tubes had been taken out by laparotomy and he found the eyes rarely if ever affected. He thought that the disease would wear itself out in time and did not believe it often caused sterility as several observers had reported cases in which the woman later had borne children.

Dr. SMITH in closing said that in his work, using ordinary precautions, he had almost no hospital epidemics. He thought the pessimism resulted from the fact that many cases reported as relapsed had been reinfected. He said that with a prolonged douche of permanganate and the application of some silver salt over a considerable period of time and with the treatment continued after the patient returned to her home for a number of weeks he saw no reason why she should not recover. He reported two cases of pus tubes in children under six occurring in their hospital within the last two years. He reported no success with vaccine.

**Roseola Infantum.**—Dr. JOHN ZAHORSKY of St. Louis reviewed the history of the use of the term and its disappearance from medical literature and made a plea for its return, as it described a positive, characteristic clinical syndrome. He reported numerous cases from his experience that could not in any way be confused with any other condition and said that because of this fact it was deserving of a classification in literature.

Dr. G. P. GENGENBACH of Denver said that it was an important condition to recognize in hospital work because, not being contagious, it was necessary to distinguish it from scarlet fever which it somewhat resembled in appearance. He had not found as high fever as Dr. Zahorsky reported.

Dr. H. W. CHENEY of Chicago thought it better to use the general term German measles to avoid confusion. He said that he had not always found German measles contagious.

Dr. ZAHORSKY in closing the discussion said that the disease was never contagious and was so positively defined that he thought it wrong to call it German measles.

**Atypical Forms of Meningitis (Posterior Basic Meningitis; Aseptic Meningitis).**—Dr. A. SOPHIAN of Kansas City, Mo., read this paper giving the clinical symptoms, laboratory diagnosis, and treatment of posterior basic meningitis; the etiology, clinical symptoms, laboratory findings, diagnosis and treatment of aseptic meningitis. He said that in practically every case of posterior basic meningitis the prognosis was fatal, and urged most careful diagnosis so that if the physician in charge did not wish to treat the case he would not aggravate it by wrong treatment. He reported that out of fifteen cases two definitely recovered, so that there was some little hope of recovery which should not be mitigated by wrong treatment.

Dr. JOHN LOVETT MORSE of Boston said that a few years ago it had been expected that very definite diagnoses could be made in all cerebrospinal conditions by lumbar puncture, but as it was studied more carefully it was found that differential diagnosis was not easy. He reported a case of posterior basic meningitis seen recently in which the fontanel had been depressed. He punctured the ventricle and the fluid did not run out under pressure. He considered the condition almost hopeless and said that his experience with serum had been discouraging. He did not consider lumbar puncture at all dangerous.

Dr. SOPHIAN in closing said that in tapping the ventricle the stilet should be left in the needle this would become clogged with brain substance. He thought the only dangers possible were injury to the basal ganglia and hemorrhage, but these were overcome with selection of the proper site.

**Leucocyte Counts in Epidemic Meningitis and Pneumonia.**—Dr. JULIUS H. HESS of Chicago had found few studies of the leucocyte count devoted to infants and after reviewing it in its relation to infections in general gave detailed findings in fifty cases. He said that blood counts could only be valuable when considered with other clinical symptoms. From the counts made in epidemic meningitis before, during, and after treatment by serum he concluded that each case must be studied individually not only as to the presence of meningitis, but as regards secondary infections, that the blood count was of no especial value, and that lumbar puncture promised the most help. From the leucocyte counts in different types of pneumonias he found that, contrary to ordinary teachings, almost all pneumonias in children from three to five years were of the lobar type, that the cases described at autopsy as bronchial were of secondary nature. He thought this a valuable aid to diagnosis and said that generally a high count indicated a strong infection.

**Precocious Menstruation.**—Dr. C. P. GENGENBACH of Denver classified the condition as referring to children having more or less regular periods of menstrual flow before the age of puberty, and not to the bloody discharge from the vagina occasionally seen in new-born infants without recurrence. In his experience it had usually been accompanied by other signs of precocious development and this would seem from examination of the literature to be quite generally the case. The case he reported menstruated quite regularly from the tenth month and developed very rapidly. He wished to know if in these cases which he thought probably pathological and certainly abnormal it was permissible to administer some glandular remedy to counteract the tendency to precocious development.

**Clinical Report and Postmortem Findings in the Case of a Child with a Congenital Heart Disease Dying from Acute Nephritis.**—Dr. H. M. MCCLANAHAN of Omaha read this paper, describing the case of a large, well nourished infant which died from a congenital heart lesion aggravated by nephritis. He thought it very probable that the child would have recovered from the nephritis had it not been for the heart lesion. Postmortem examination showed no enlargement of the chest, muscles dark and soft, no fluid in the abdominal cavity, although there were evidences of there having been some, bile passages normal, stomach exceedingly dark, pancreas dark, liver greatly congested, lungs not congested, both kidneys firm, the heart the size given by Gray as that of a normal adult, heart muscles dark and reddish, its cavity containing a large amount of blood, almost no clotting, the veins enormously enlarged, and free mingling of venous and arterial blood. He was able to find no literature on the subject.

Dr. J. ZAHORSKY of St. Louis reported having a case in which these peculiar symptoms were presented. He had found some literature showing that children with congenital heart disease gave large red blood counts.

Dr. H. LOWENBURG of Philadelphia said he had had one case in which the count was between eight and nine million in which there were clubbing of the fingers and heart murmurs. The autopsy in this case revealed a normal heart but a chronic interstitial pneumonia that gave few physical signs.

Dr. MCCLANAHAN in closing the discussion said he had searched the *Archives of Pediatrics* ten years back without finding the condition touched upon. He said that in his experience all cases of congenital heart disease ultimately died of some intercurrent affection. One case, carefully guarded from acute infections, had lived to the age of sixteen.

**The Hospital Management of Contagious Diseases.**—Dr. D. L. RICHARDSON of Providence, R. I., said that his object in presenting this paper was to give the technique and results obtained by rigid asepsis in the care of patients suffering from contagious diseases. He said that no matter what the method of separation was the nursing employed was the greatest factor, and it was therefore necessary to get the full cooperation of the nurses to prevent the spread of contagious diseases, but once this was done and the technique carefully followed there was no danger in admitting contagious diseases, with the possible exception of measles and chicken pox, into any general hospital. He said that the theory of air transmission of disease had been practically exploded in the French and German hospitals so that the matter was one of absolute sterilization of everything that came in contact with the patient. He described in full the arrangement of buildings, construction of rooms, care of apparatus, utensils, and garments used in the Providence Hospital and said that with their method no prophylactic antitoxin had been used, nor antiseptic by the attendants in washing their hands, nor was fumigation necessary.

Dr. H. E. ROBERTS of Minneapolis wished to know how nurses were trained for the aseptic nursing.

Dr. RICHARDSON in closing the discussion said it had been found impractical to have pupil nurses work in the isolation ward because of the short time they were at the hospital, but said that any nurse who had had two months or more of general preliminary ward work could be trusted with the aseptic nursing.

**Federal Children's Bureau; the Law, the Organization, the Scope of Its Present Work.**—Miss JULIA C. LATHROP of Washington gave this paper as a report of work done during the one year that the bureau had been in operation. She said that its field as defined by the law was one of investigation and report, that from knowledge of conditions existing municipal and Federal organizations

might go intelligently to work to better conditions. The first investigation was the investigation of infant mortality in small towns. She said that as it had been conclusively proved that the mortality in cities was decreasing while that in rural districts was increasing the first efforts were directed toward small towns. Johnstown, Pa., was selected because it had birth registration. She urged particularly the cooperation of every physician with the bureau and the Census Bureau in urging birth registration, placing direct emphasis on its value as an expedient in reducing infant mortality, and as an aid in protecting the lives and rights of children. She had found little diffienlty in enlisting the cooperation of parents when the purpose of the work was explained to them, as shown by the fact that out of 1,558 schedules only two were refused. She said that from the work done so far apparently all that was needed was to popularize the movement to make it a success. The plan included the establishment of a complete working library of everything pertaining to child welfare, the nucleus of which was already started.

Dr. C. F. Warher of Fort Madison called attention to the easy manner in which funds are appropriated for patriotic demonstrations and civic improvements and said that evidently when a public demand was made for measures that would conserve the health of the coming generations they would be forthcoming.

**The Etiology of Artificial Feeding; a Plea for the Study of Breast-Milk Problems.**—Dr. H. Lowenburg of Philadelphia in this paper gave a very careful résumé of the causes leading up to the discontinuance of breast feeding, and concluded from his experience that in a very large number they were fallacious. He said that even abscess of the breast he had not found to indicate complete withdrawal of the breast. He thought that the factors were largely psychic, economic, and social; and that a permanent, irremovable or organic obstruction to successful breast feeding rarely existed. He emphasized the need for impressing mothers with their responsibilities toward their children, and physicians with their responsibility when they allowed mothers, for slight cause, to discontinue nursing their babies. He thought that natural feeding was the only sane and safe way, and that the profession spent time in studying artificial feeding that might better be spent in learning how to deal with problems of breast feeding and nutritional and digestive disturbances of the breast fed. He had found economic and social reasons most difficult to overcome because their origin was in the present social condition. He thought that the practical working out of the problem would be by cash payments made to nursing mothers.

Dr. Rosenthal-Thompson of Grand Rapids, Mich., said that there was a close connection between this study and the work of the Child Welfare Bureau, and that when poor mothers were given protection and good food they would be able to nurse their babies. In thirty years of practice she had found few mothers actually unwilling to nurse their infants.

Dr. J. Zahorsky of St. Louis reported great difficulty in enabling all mothers to nurse their infants who would gladly do so if they could. He found acute indigestion in many breast-fed infants, and many others that did not thrive until artificial feeding was resorted to. He thought that when therapeutic measures, such as lengthening the time between feedings, did not improve conditions it was not rational to continue breast feeding.

Dr. C. F. Wahrer of Fort Madison, Ia., laid the fault largely at the door of meddlesome nurses or members of the family and thought if physicians would assert themselves a little more and teach the mothers the dangers of artificial feeding and the pleasure to themselves of nursing their infants little trouble would be found.

Dr. H. W. Francis of Bancroft, Neb., reported little trouble in rural districts, but said when there was a case it usually proved to be one where it was really not best for the mother to nurse the child. He said that in cases where the mother's milk did not agree with the infant he had often given citrate of soda at each nursing time with good results.

Dr. L. R. De Buys of New Orleans though the care of the breasts before confinement was deserving of more attention than it usually received. He reported many cases where mothers extremely anxious to nurse their infants were unable to do so, and thought attention to the nipples would help many of these. He had been able to help mothers with scanty milk secretion to nurse their babies for six or seven months by giving all the milk secreted and enough artificial food to supply the lacking nourishment to the child. He said that by this method the supply was frequently increased to such an extent that after two or three months the breasts are supplying nearly all the food the child needed. He said that every child should not be weaned because the stools were not normal, that it sometimes took a month to adjust the child to the breast.

Dr. G. P. Gengenbach of Denver thought that of those who would like to nurse but could not, there were two classes—the nervous and those whose milk was too rich. Of the latter he had found many and obviated the difficulty by giving the child some water and allowing it to nurse only a little while, so that it did not get the last of the breast secretion which carried the most fat. Nervous mothers to his mind presented a graver problem, but he reported good results with sedatives and, at the same time, tonics to build them up.

Dr. C. H. Johnson of Grand Rapids thought only two contraindications to natural feeding presented—namely open tuberculosis and advanced heart disease. He thought that aside from these all other difficulties could be overcome and the mothers educated to nurse their babies. He pointed out the fact that the ill effects of artificial feeding followed the child even to the tenth year, and thought if mothers generally understood this the effort to overcome difficulties to nursing would be more determined. He thought no child which showed an increase in weight should be weaned even if there was persistent vomiting and green stools. He said it was seldom the baby's fault that it could not nurse.

Dr. Stewart of Iowa City deplored the practice of physicians in turning the mother and child over to the nurse after the second and third day, and neglecting them at the time of getting up. She thought that if physicians would attend them carefully until after the getting-up period few could not nurse, at least, for three months even if after that time, on account of weakness, they could not do so.

Dr. Frank C. Neff of Kansas City thought the general criticism of physicians might have applied in the past, but scarcely would now. He said his experience proved many mothers took the baby off the breast because they thought they had not enough milk. He emphasized the need of education in such instances so that use would be made of what there was. He had had remarkably good results in such cases by obtaining supplemental supplies from mothers with more than they needed and urged physicians to try this plan.

Dr. E. O. Benson of Chicago reported little difficulty in getting mothers to nurse their infants. He said that literature was fast coming into the hands of the reading public as to the ill effects of artificial feeding and the increased resistance of the breast-fed to infectious diseases, so that he had more trouble in overcoming difficulties to nursing than he had in getting mothers to nurse. He did not agree that too much study was spent on artificial feeding because where it was necessary it was a grave problem and too little attention paid to it often resulted disastrously. He found many cases where mothers in their anxiety to nurse their babies were eating too rich foods themselves with the mistaken idea that it would increase the quantity and richness of their milk, and emphasized the need for a simple and nourishing diet.

Dr. Henry Dwight Chapin of New York wished to have Dr. Lowenburg explain what he would do in a case where the mother was willing to nurse the child, where the doctor and the nurse advised it, but where the milk was poor and scanty. He said that in the Department of Agriculture investigations showed that all animals did not have a potential possibility to give milk, and he wondered if this might not be at times the case in the human being.

Dr. Lowenburg in closing said that his experience did not warrant the belief that many mothers were unable to nurse. He did not consider indigestion, green stools, curds, or colic an indication for artificial feeding, but said as long as there was increase in weight the breast milk was indicated. He thought many infants were fussed with too much and watched too closely, and said that many, if no attention were paid to anything but the weight, would get along all right. He thought systematic study of stools of the breast-fed would probably show why they were green. He thought careful attention to the breast before the birth of the child and throughout the nursing period was the province of the physician, and should not be relegated to the nurse. Considering Dr. Chapin's hypothetical case he said that he would give what milk was secreted and supplement with artificial feeding, meantime studying the milk and if some element was lacking supply it in the food of the mother; give her abundance of water and sometimes Southworth's soup and in all probability the supply would increase. His experience showed that instances where the

supply did not increase occurred in the very obese where the breast was mostly fat with little glandular substance.

*Friday, June 20—Fourth Day.*

JOINT SESSION WITH THE AMERICAN ASSOCIATION OF MEDICAL MILK COMMISSIONS.

DR. OGDEN M. EDWARDS OF PITTSBURGH IN THE CHAIR.

**Annual Report of the Relation of Bovine and Human Tuberculosis.**—Dr. M. P. RAVENEL of Madison, Wis., in this paper called attention to the large number of more or less permanent deformities in children resulting from bovine tuberculous infection, in addition to the deaths attributable to this cause. He said that a large number of cases studied showed very rapid progress of the disease following initial infection, that the greatest number occurred in children, gradually diminishing as the milk-drinking age was passed. He thought that this was a strong plea for more care in milk supplies.

**Certified Milk.**—Dr. T. C. MCCLEAVE of Berkeley, Cal., pointed out the common confusion of certified and pasteurized milk and gave full, definite definitions of the terms, reviewed the history of the origin of certified milk and the origin and operation of the Milk Commission. He said that fundamentally all recent movements for the conservation of infant life had their origin in the pure milk movement. He emphasized the care that was taken in supervision of the hygiene and sanitation of dairies, construction of the stables, proper selection of cows, and freedom from bacteria, and made a plea for uniform requirements throughout the States.

Dr. J. W. VAN DERSLICE of Chicago thought Brown Swiss cows preferable to Holsteins because in the latter it was almost impossible to get a uniform fat content. He called attention to their extreme susceptibility to climatic changes which affected the fat content. He reported poor results from the use of milking machines but thought ultimately the machine would be perfected to a practical point. He thought that when a machine was constructed that would not cause disorders of the udder it would be an improvement over hand milking.

Dr. HENRY L. COIT of Newark, N. J., emphasized the need of the producer's co-operation in getting a pure milk supply and said that Mr. Stephen Francisco as the first producer of certified milk deserved as much credit as the originators of the movement.

Dr. JOHN ZAHORSKY of St. Louis said that in his section of the country there was great difficulty, on account of the prolonged hot weather, in keeping down the bacterial count and thought that there should be variations made in the requirements throughout different parts of the country.

Dr. C. H. JOHNSON of Grand Rapids took exception to this and said that almost any commercial milk during cold weather could give a bacterial count of 10,000 or less and that if certified milk dealers were to be protected they should not have to go into competition with the commercial milk dealers during the cold weather.

Dr. MCCLEAVE in closing said that by mixing the herds the fat content could be brought up to the requirement, but emphasized that the low fat content of the Holsteins was not a disadvantage as the milk was designed primarily for infant feeding. He thougbt the uniformity of the supply in other respects was of more importance than the fat content. He thought the value of the milking machine problematical until an efficient method of sterilizing the rubber tubes was found, but that when it was it would be an advantage as probably three-fourths of the infection was from milkers. He thought no lowering of the demands as regards bacterial count should be made as that was one of the special features of certified milk. He said that one of the objects of the commission was to bring about a milk supply that would guarantee to people in all parts of the country uniform purity.

**The Cost of the Production of Certified Milk.**—Mr. STEPHEN FRANCISCO of Fairfield, N. J., the first producer of certified milk, had made a careful analysis of all of the increased costs of producing certified milk over ordinary milk and announced it to be a trifle over 9 cents a quart. He called attention to the constant inspection and weeding out that was necessary and said that unless each one engaged on the farm was interested in obtaining perfect results pure milk could not be guaranteed.

**The Cost of the Production of Certified Milk.**—Mr. W. E. MILLER, a producer of Lebanon, Ohio, found practically the same cost of the production of certified milk. He thought too much attention was probably paid to the spectacular features of a certified milk farm, all of which had to be figured in the production cost. He said that to make the measure of the greatest good to the greatest number all interested must co-operate to reduce the price to the consumer within reach of the greatest number of families. He thought the least amount of supervision that would guarantee pure milk to the public was all that was necessary and asked the cooperation of physicians in this respect.

Dr. T. C. MCCLEAVE of Berkeley, Cal., said that the increased equipment and expense of running a dairy to produce certified milk aside from the inspection and veterinary fees all increased the price of certified milk, but that as the farms studied efficiency and business methods these could probably be decreased a little.

Dr. JOHN ZAHORSKY of St. Louis asked if depreciation on machinery and interest on the investment should not be added to the cost of certified milk.

Dr. J. W. VAN DERSLICE of Chicago said that in Chicago two plans were used in obtaining certified milk. By one the number of bottles required each day was ordered. By the other all of the output was taken at a flat rate which was found to be the better plan for all concerned. He thought unless the entire output could be disposed of there would be a loss at the end of the year. He thought the keynote of the situation was co-operation, that when all having to do with milk supplies co-operated for a clean supply even in commercial milk the bacterial count would be reduced to a minimum.

Dr. OTTO P. GEIER of Cincinnati said that with the fees obtained by the commission they were able to maintain a laboratory which was at the disposal of physicians; also to advertise the certified milk stations, which was of great benefit to the dairymen, so that all of the cost of the commission's fees could not be called a dead weight on the cost of maintaining the farm. He thought a per-bottle tax the best plan of affixing fees so that the large farms would bear their proportionate share of the expense.

Mr. FRANCISCO in closing the discussion said the market milk had moved right along up a close second to certified milk and that as the dairies for certified milk were perfected general dairies would follow their methods.

Mr. MILLER in closing discussion of his paper said that the cost of upkeep and depreciation were negligible factors, as with the good care given the animals and the constant improvements made on the apparatus they were increasing in value all of the time. He said he had practically no loss from the tuberculin reaction.

**The Efficiency of the Medical Milk Commission Graphically Illustrated.**—Dr. HENRY L. COIT, of Newark, N. J., with a graphic chart described the principles governing the work of the medical milk commission. He attempted to show the relative importance of practical dairy hygiene, experienced veterinary supervision, chemical and bacteriological supervision of the hygiene of stock and production, and the medical supervision and the control of the health and personal hygiene of the dairy employees, in order to insure a product uniformly reliable and safe as based on fixed standards.

**The Effect of Barn Operations upon the Germ Content of Milk.**—H. A. HARDING of Urbana, Ill., presented a series of comparisons made between conditions ordinarily obtaining in dairy farms and those after extreme niceties as to cleanliness had been observed. In each instance sufficient tests were made to render unjust any claim made that the results applied to one time only. From these studies he found there was no effect upon bacterial count of milk after whitewashing the walls, that atmospheric conditions had no effect, that wet cleansing of animals had no advantage over dry, that clipping made no change. He did find that pails must be very carefully sterilized and then covered until used or the bacterial count would be raised. From these studies he concluded that undue attention had been paid to what *looked* clean and that dogmatic assertions had been made without investigation into the facts.

Dr. C. H. JOHNSON of Grand Rapids wished to know if the dust content of the air had any effect upon the milking machine as shown by the bacterial count.

Dr. T. C. MCCLEAVE of Berkeley, Cal., wished to know if comparative tests had been made with open and closed pails. He thought if not the apparent safety might lie in the use of the closed pail in the experiments reported.

Dr. J. W. VAN DERSLICE of Chicago said that it had been quite definitely proved that it was the care of the milk during and after milking that influenced the germ count rather than equipment. He thought in spite of this that everything should be done to have a clean looking dairy so that all employed about it would be stimulated to especial pains in the matters which did affect the germ count in the milk.

Dr. Otto P. Geier of Cincinnati thought facts such as reported in the paper should not be made public because of the unfortunate influence they would have on the movement for clean milk. He cited the University of Wisconsin as deserving of sharp criticism because of its stables, as he thought the psychological effect on students of a poorly kept dairy was bad.

Dr. Oscar Dowling of Shreveport, La., said that they had had great trouble in effecting sanitation in the milk supply. Seventeen out of 32 dairies had been closed on account of poor milk. He had found three doctors selling milk to their patients under every condition of poor hygiene and thought that any one who sold milk, even if but a quart a day, should be obliged to comply with the requirements. He said that in ordering milk to drink at soda fountains and in hotels he had been able to taste dung and thought that this should be eliminated.

Dr. Henry Coit of Newark, N. J., thought that there was no milk produced in which now and then the taste of dung could not be detected but thought visible dirt could be eliminated.

Mr. H. A. Harding in closing the discussion said that no tests were made to compare the open and closed pail in this series because he had already performed these tests and established the importance of the closed pail and published the findings in detail. He thought the closed pail cut off fully 50 per cent. of the germ count. He thought the University of Wisconsin had been too severely scored because from all of the studies made he found that they were neglecting nothing that really affected the germ count of the milk. He thought that clipping was not necessary because what germs came from that source came from the skin and by leaving the hair long and cleansing it by brushing particles of epidermis were prevented from dropping into the milk. He thought unless a man had actually made a series of comparative studies he should not attempt to criticise the sanitary conditions of a dairy, because he discouraged the dairyman by dogmatic assertions regarding things that made no material difference to the germ count. He said that their studies showed surprisingly few germ cells in dirt, so that dirt on the top of milk was no indication of its impurity, and that if one attempted to insist that there should be no taste of dung he might as well wipe milk from the dietary because there was no method, however exact, that would prevent it at all times.

---

SECTION ON PRACTICE OF MEDICINE

Dr. W. Jarvis Barlow, of Los Angeles, in the Chair.

*Wednesday, June 18.—Second Day.*

**Clinical Aspects of Hypertension.**—Dr. Joseph L. Miller of Chicago read this paper in which he summarized the present knowledge affecting the etiology, pathology, and treatment of high blood pressure. Absence of albumin and casts did not necessarily exclude kidney changes and slight changes might exist in kidneys apparently normal both in appearance and function. It was doubtful if the functional tests now applied ever disclosed more than the grosser lesions. It was difficult to explain the marked fluctuation of pressure in patients with hypertension. It seemed that nervous influences were a definite factor in the production of hypertension. A few cases might be explained by arteriosclerosis, but it was probable that heart hypertrophy was always secondary to some defect in the kidneys. In these cases of hypertension it was difficult to make a definite prognosis as there was no way of estimating exactly the strength of the arterial walls or of the heart muscle. The phenolsulphonephthalein test was the most reliable one now had for determining the kidney function. It was possible for an individual to have a blood pressure of 200 mm. and yet show no kidney lesion. When a patient had such a pressure overexertion should be avoided as cardiac decompensation or cerebral hemorrhage was liable to develop. In these cases cerebral symptoms were common and dyspnea was a warning against overexertion. Of course, the more marked the renal changes the graver the prognosis. Retinal changes were not so important. A patient with a blood pressure of 170 mm. or less was not in any immediate danger if his habits were well regulated. These cases of moderate hypertension often showed marked fluctuation in the blood pressure. Drugs were less important in the treatment of these cases than attention to hygiene and elimination. The protein intake should be restricted according to the extent of renal involvement. The excessive use of tobacco and severe strain both physical and mental should be avoided. Moderate physical exercise was both safe and beneficial if there was no dyspnea. Digitalis by way of the mouth did not raise the blood pressure. The iodides were of no special use unless syphilis was present. Other drugs were of slight value. If one expected to reduce the blood pressure he would be doomed to disappointment in the vast majority of cases.

**A Comparison between Jacquet's Sphygmograph and Crehore's Micrograph in Cardiac Tracings.**—Dr. Alexander Lambert of New York read this paper and gave a lantern slide demonstration of Crehore's micrograph and of the curves recorded by both instruments. He had been working with these instruments for two years and thought that he was justified in reporting on the work though there were still many points in connection with the tracings which were not understood. The two instruments showed similar occurrences in the cardiac cycle, the micrograph showing greater detail and also occurrences which the sphygmograph was unable to register. The micrograph registered in tenths of seconds while the sphygmographs registered in fifths. The curves in auricular fibrillation were shown by the micrograph but not by the sphygmograph. The Crehore instrument magnified the arterial vibration about 50,000 times. The tracing in auricular fibrillation showed that the auricle contracted in bundles.

**The Diastolic Pressure.**—Dr. Louis Warfield of Milwaukee read this paper. He stated that clinically hypertension was mostly an effort at compensation, and in this sense it was physiological. The advantages of measuring the diastolic pressure rather than the systolic had not been appreciated and the methods of measuring diastolic pressure had not been uniform or accurate. The auscultatory method was the most practical that we had had hitherto. It had been customary to take the diastolic pressure at the point of disappearance of all sound. Dr. Warfield showed that this was not the right time to take the diastolic pressure but rather at the point of dull tone. At the end of the third tone the diastolic sound was sharp and suddenly became dull and there was a decrease in pulse rate. At this point the pressure should be taken. In normal individuals it was not difficult to determine the diastolic pressure, but in irregular hearts it was doubtful if one could obtain the pressure even with approximate accuracy.

**Clinical Significance of High and Low Auscultatory Pulse Pressure.**—Dr. Willard J. Stone of Toledo, Ohio, presented this paper in which he described the results of his observation in 170 cases in which he had endeavored to find out the significance to be attached to certain high and low auscultatory readings. He concluded as follows: (1) The determination of systolic and diastolic pressures by the auscultatory method was to be preferred to the palpatory method for systolic, and column or indicator oscillation for diastolic pressure, because of greater accuracy. (2) The readings were slightly higher by the auscultatory than by the palpatory method. (3) The pulse pressure measured the energy of the heart in systole in excess of the diastolic pressure. For clinical purposes it represented the load of the heart. Under normal conditions it was approximately 50 per cent. of the diastolic pressure. The myocardial load might therefore be expressed by the fraction $\frac{\text{pulse pressure}}{\text{diastolic pressure}}$ or $\frac{\text{P. P.}}{\text{D. P.}}$. (4) Since the diastolic pressure measured the peripheral resistance it was a better index of hypertension than the systolic pressure. A sustained diastolic pressure of 100 to 110 signified hypertension. The diastolic was less influenced by physiological factors than the systolic pressure. (5) The comparison between systolic, diastolic, and pulse pressures was of clinical value in the interpretation of circulatory changes and of more importance than the estimation of systolic pressure alone. (6) In arterial hypertension and myocardial decompensation in the broad sense, the pulse pressure and heart load was increased, as a rule, the overload factor varying greatly from 50 per cent. to 175 per cent. in this series. The greater the overload factor the greater was the danger of myocardial exhaustion. (7) In circulatory failure due to shock, to many acute infections, and to hemorrhage, the pulse pressure was low. This was the result, it was believed, of factors which had influenced arterial tonus and peripheral resistance with rapid pulse rate, increased respirations, and lowered venous pressure. (8) In acute infections a sustained pulse pressure warranted a more favorable prognosis, as a rule, than a low pulse pressure, other things being equal; although the change from a normal to a low pulse pressure in circulatory failure might occur very rapidly. As a rule the lower the pulse pressure, the greater the danger of circulatory failure. (9) From this point of view low pulse pressure in circulatory failure involved a consideration of complex peripheral changes in addition to the myocardial factor. (10) The pulse pressure multiplied by the pulse rate did not give a reliable index of systolic output in circulatory shock

since the pulse rate clinically increased out of proportion to the fall of the pulse pressure. This shortened the time during which the left ventricle was filled during diastole and lessened the systolic output although by the formula pulse rate multiplied by pulse pressure the unit volume output might appear to be increased. (11) The pulse pressure estimation in this series did not show marked variations from day to day except in a few more or less neurotic individuals.

**The Pathology, Symptomatology, and Treatment of Slow Forms of Perpetual Arrhythmia.**—Dr. Hugo A. Freund of Detroit, Mich., read this paper. He first reviewed the anatomy of the stimulus conducting system of the heart, and gave lantern slide demonstrations illustrating the changes found in the sinaauricular node and in the auriculoventricular node in cases of slow perpetual arrhythmia. The symptoms and signs in cases of rapid perpetual arrhythmia were compared with those of the slow type. There were two forms of the slow type, the primary and the secondary. The primary were distinguished by the fact that the ventricular rate was never rapid; the patient experienced no palpitation and precordial distress; slight exercise did not increase the rate. These cases lived longer than any others and were seen in older individuals. In the secondary type the arrhythmia was gradually converted from rapid to slow. These were the hearts that showed fibrous connective tissue infiltrating the conduction system. There was a tendency to decompensation in this type and few patients recovered and these only with great difficulty. Patients having the slow forms of perpetual arrhythmia required no treatment. Tracings were shown illustrating auricular fibrillation of the coarse and fine varieties with rapid and with slow response. In cases requiring treatment this was best established by digitalis.

Dr. Louis Warfield of Milwaukee, Wis., said that Dr. Stone's paper stating that diastolic pressure was the most important factor in blood pressure estimation had interested him very much. It seemed to him from the study of a few cases that it was not the constant high pressure but the high diastolic pressure that was important. The heart compensated a high diastolic pressure by a high systolic pressure. If the resistance increased the heart worked at a maximum rate and the result was broken compensation. He had been surprised to find the overload comparison correct in many cases; it gave something upon which to work. The myocardium controlled the circulation and any way of measuring the overload gave one an advantage in making a prognosis in heart disease. It was difficult to measure the diastole and systole in irregular hearts and in extrasystole. In patients suffering from decompensation more depended on making a prognosis on the state of the patient than on the blood pressure. They were only beginning to study the diastolic pressure but it seemed to him that other things being equal a high diastolic pressure indicated a more grave prognosis than a high systolic pressure. If one were able to take only one pressure it would be better to take the diastolic rather than the systolic.

Dr. Henry Elsner of Syracuse, N. Y., said that the value of this discussion was in proportion to its practical benefit to the average man who wanted these things interpreted. Many years ago Stokes said that the key to the heart lay in the heart muscle. He reached a sane conclusion when he called attention to the myocardium. Hypertension in itself was a question to be considered with the greatest circumspection. They all seemed to have an overwhelming desire to use the sphygmograph. The laity had learned that there was such a thing as high blood pressure and came to the physician saying, "Oh, doctor, I have blood pressure," and he replied, "Thank God you have." High blood pressure in itself was of little importance except as indicating the necessity of keeping an eye on the patient, and this must be done in a tactful way. The patient with a moderate hypertension but no other heart lesion and whose urine was normal need not feel despondent provided he could be led to right living. Hypertension with hypertrophy of the heart in a patient whose compensation was comfortable required watching but not continuous medication. When there were positive renal symptoms without marked hypertension treatment was directed to the renal condition. Where there was high blood pressure, positively renal symptoms, palpable arterial and other symptoms, iodides ought to be given over a long period. There was a growing tendency to decry the nutrites. They had no real value in decreasing the blood pressure but they relieved sensory symptoms. The graphic methods needed interpretation, but they taught heart physiology and pathology in a definite way and would lead to a safer prognosis. Dr. Elsner said he could not leave the subject without calling attention to the increased frequency of these heart conditions. In referring to angina pectoris Rush said he had seen but one such case and knew of the existence of one other. A great change had taken place in the present day. This was due to the stress of modern living.

Dr. W. S. Thayer of Baltimore said that Dr. Lambert had demonstrated that Crehore's micrograph was the more delicate instrument. To carefully interpret the results required careful work but in a few years he felt sure that important results would accrue. After all to the practical physician blood pressure was of more value from the point of view of prognosis than of diagnosis. He said that his therapy in cases of hypertension agreed with that of Dr. Elsner. There was danger from the use of the nitrites in chronic nephritic conditions with hypertension. He recalled a case of uremia which he believed had been caused by the use of the nitrites. The old cases with irregular heart sometimes got better but the arrhythmia remained; however, perpetual arrhythmia was not a good term because the arrhythmia did sometimes disappear. Digitalis helped these cases but it was sometimes followed by the recurrence of an old arrhythmia.

Dr. H. S. Munro of Omaha, Neb., said that these cases presented the general problem of the individual, digestion, circulation, nervous system, habits; the individual was the end product of all these and one had to approach the pathology of these cases that they were discussing by the indirect rather than the direct way. The nervous element was often the main feature; one also found high-blood pressure in connection with defects in elimination. One should study the social and economic side of these cases and endeavor to regulate the life of the patient rather than to specialize too much on the local defect.

Dr. James M. Anders of Philadelphia said that clinical hypertension was a cause of many unsolved problems which required further study. There were cases with no definite etiology either with the heart, kidney, or other viscera, and these were called cases of physiological hypertension. He felt sure that this class would undergo diminution. Alcohol, tobacco, and nerve strain were the important factors in producting this condition. Constant hypertension led to arteriosclerosis if watched long enough. Therefore cases of hypertension formed an important group clinically considered. Surely the profession in America was not sufficiently impressed with the importance of recognizing the nervous element in the treatment of these cases. Rest in bed for several weeks, rather liberal feeding, and the use of the nitrites were recommended in the treatment of new cases.

Dr. Thomas McCrae of Philadelphia said that the burden of Dr. Miller's paper was that there were many cases of hypertension that had nephritis. A patient might have nephritis and not have albumin. The better the physician the more he hesitated to say what nephritis was. Sometimes the changes that might be attributed to nephritis were due to advancing years. What about the high blood pressure found in women during the menopause? It later returned to normal. There was also a group in which there was a disturbance of pressure due to nervous influences.

Dr. Richard C. Cabot of Boston said that the presystolic murmur lasted only one-tenth of a second and he wondered if this could be recognized. Vascular crises accounted for the cerebrospinal symptoms referred to by Dr. Miller.

Dr. A. C. Griffith of Kansas City agreed with those who thought that hypertension was often dependent on the nervous phenomena. He had had one case in which the pressure was reduced by rest in bed after the iodides had failed. Where the arteries, kidneys, and functional activity had not changed for the period of a year he attributed the case to neurasthenia.

Dr. Lambert in closing the discussion called attention to the fact that there were curves in a heart without valvular lesion where the muscle was badly damaged. He had not decided in his own mind what all the curves meant. Dr. Stone's paper had really added to the sum total of their knowledge.

Dr. Miller of Chicago said that nervous conditions might be responsible for the transitory condition of high blood pressure, but not for the permanent ones. In hypertension the urine should be examined again and again over long periods of time. He believed that the functional kidney tests in the patient with high blood pressure if made again and again would, in the majority of cases, show kidney changes. He had tried digitalis before and during the kidney involvement and it did not have any effect on the blood pressure.

Delinquents, psychology of, 75.
Delirium, abstinence, of alcoholics, 80.
Dementia præcox, 489; præcox, cyanosis in, 30.
Dentists, royal, 414.
Dermatology, the internal secretions in relation to, 1045.
Dextrocardia, familial, 721.
Diabetes, and gout, parallelism between, 499; and life insurance examination, 312; and removal of tumors, 490; carbohydrate treatment in, 950; drugs in the treatment of, 736; efficacy of lactic acid bacilli in, 142; gangrene due to, treatment of, 767; high altitudes and, 1034; hypotonia of eyeball in coma of, 1180; in infancy and childhood, 766; in pregnancy, the treatment of, 1096; insipidus, and the hypophysis, 309; modern aspect of, 162; newer opinions concerning, 220; ozone in the treatment of, 736; pancreatic lesions in, 552.
Diachylon as an abortifacient, 1179.
Diagnosis, changing one's, 598; a case for, 412.
Disease and accident malingering in, 543.

Diacetic acid, a new test for, 908.
Dialysis, Abderhalden's procedure of, in the explanation of psychoses, 493.
Diarrhea, pancreogenic, 1083; treatment of, 92.
Diathesis and constitution, overlapping of, 1128.
"Dichotomy" in Germany, 1173.
Diet, habit of, and gastric function, 1156.
Digestion and infection, 1,000; diseases of, blunders made by nature in causing, 613.
Digitalis, action of, in various forms of heart disease, 216; influence of ions upon action of, 111; poisoning with heart block, 594.
Diphtheria, 825; a new Behring serum in, 903; and its present-day problems, 940; as a folk plague, outlook of, 806; avian and human, 444; hemiplegia due to, 1034; in institutions, 352; in the Philippines, 351; lessons from the recrudescence of, in Germany, 251; prophylaxis and treatment of, 448; the phenomenon of Arthus in, 346.
*Diplodia zeæ*, and pellagra, 629.
Diplomellituria, 1000.
Discipline in the care of the sick child, 958.
Disease, monthly incidence of, 30; the scope of, 424.
Disinfection, preventive value of, 396.
Disk, choked, significance of, 217.
Dispensary, and hospital abuse, 546; free functions of, 351.
Dissection, on coroner's notice, 480.
Diuresis, water in relation to, 827.
Diverticulitis, 537; acute, resection of sigmoid for, 1102; causing diffuse purulent peritonitis, 173; of sigmoid, 728.
Downes, W. A., primary splenomegaly of the Gaucher type; report of a successful splenectomy, 697.
Drugs, old and new, 1087; standardization of, 1082; therapy of, foundations of, 216.
Druskin, S. J., oxygen in the toxemia of pregnancy, 166.
Ductus arteriosus, patent, 775.
Dunham, J. D., röntgenoscopic examinations versus clinical methods in the diagnosis of gastric disease, 1066.
Dunton, W. R., Jr., occupation as a therapeutic measure, 388.
Duodenum, bacteriology of, 594; new instruments for, 1119; tubes of, use of, 950; ulcer of, complications of, 870; ulcer of, etiology and morbid anatomy, 870; ulcer of, diagnosis and prognosis of, 871; ulcer of, fatal hemorrhage from erosion of gastroduodenal artery by, 229; ulcer of, in the nursling, 769; ulcer of, non-surgical treatment of, 870; ulcer of, surgical treatment of, 871.
Dust in cities, 163.
Dysbasia, angiosclerotica, 33.
Dyspepsia, chronic, surgical treatment of, 530.

E

Ear complications of infectious diseases, 397.
Eccles, R. G., the scope of disease, 415.
Eclampsia, 909; abdominal cesarean section in, 673; and the kidney, 622; hypophysis extract in, 32, 1181; symmetrical cortical necrosis of the kidneys in, 998; treatment of, 401.
Eczema, in young infants, treatment of, 138; oris, and congenital syphilis, 722.
Edema, angioneurotic, 975; neonatorum, 542.
Education, as to sex, 989; elementary concepts in, applied to medicine, 875; medical, 1146; medical, moral development in, 941; medical, path for progress in, 758 medical, postgraduate in Vienna, 721 medical, the interne year in, 1043; of public in sanitary matters, in the Philippines, 672; popular medical heresies in, 713; public health, cooperation of medical societies in, 867.
Efficiency, and fatigue, 666.
Einhorn, M., additional remarks on cardiospasm and idiopathic dilatation of the esophagus, 369; new instruments for the duodenum and small intestine, 1119.
Electrocardiophone, a new, 550.
Electricity, death by, 537, 540, 585; high frequency currents of, in trigeminal neuralgia, 78; high tension, as a remedy, 547.
Embolism, air, following prostatectomy, 719.
Emotion, grimaces of, in infancy, 172.
Emin Pasha and the mosquito origin of malaria, 1092.
Encephalomeningitis, influenzal, 827.
Endocarditis, acute streptococcal, recovery in, 171.
Endometritis, treatment of, 1134.
Entameba, infections with, in the Northwest, 1148.
Enteroptosis and military efficiency, 223.
Enuresis, and chronic digestive disturbances, 959; treatment of, 506.
Enzymes, protective, specificity of, 632.
Eosinophiles, action of *x*-rays upon, 204.
Epiglottis, suture of, 912.
Epilepsy, 749; and insanity in ancient times, 184; bromine treatment of, 542; crotalin in, 561; edema of glottis associated with, 906; in infancy, 91; phosphorus in, 677; thyroid treatment of, 320; treatment of, 1045.
Epistaxis, in childhood and youth, 483.
Erysipelas, and tattooing, 1047; in infants, treated by vaccines, 573; latent, 70, 633.
Erythema, multiforme, bacterial causation of, 1001; nodosum, and tuberculosis, 1180.
Esophagus, cancer of, palliative treatment of, 184; cancer of, surgical treatment of, 888; cicatricial stenosis of, 304; congenital atresia of, 597; extreme dilatation of, 89; idiopathic dilatation of, 396; resection of, for carcinoma, 774.
Esthetics of medicine, 723.
Ether, drop method of giving, with a closed inhaler, 938; inhaler, a simplified, 86.
Ethics, medical, 859.
Eugenics, 30; and insurance, 1182; negative, 1171; practical, 1082.
Evidence, as to effect of cocaine, 803; expert, as to probable result of injuries, 20; expert, of physicians examining plaintiff to testify as to injuries, 939; medical, leading questions, physician and patient, and disqualification as witness, 20; non-expert as to malpractice, 574; opinion, 665; speculative opinion insufficient, 276; statements to physicians as, 803.
Examinations, insurance, points to insure honesty in, 725.
Examiners, medical, a letter to, 1094; as insurance company's agents, 757; fees of, in New Zealand, 1048; local, and life insurance, 816; points for, 1048; selection and training of, 494; suggestions to: elementary principles of life insurance: 494, 587, 678, 770, 862, 954, 1048, 1140; suggestions to: life insurance companies, 35; suggestions to: the application for insurance, 124; suggestions to: the insurance interest, 311; suggestions to: the life insurance policy, 218.
Excreta, disposal of, 947.
Exercises, systematic, in preoperative treatment, 812.
Exophthalmic goiter, 540; abortive and familial types of, 849; association of uterine growths with, 822; atypical, 355; case of, cured by *x*-ray, 849; spontaneous recovery in, 216; with scleroderma and a positive Wassermann reaction treated with salvarsan, 1124.
Experts, medical, 577, 996; examination of, by court, 757; to draw inference from facts and not to decide the facts, 20.
Eye, ball of, hypotomia of, in diabetic coma, 1180; diseases of, as studied in German East Africa, 861, 910; diseases of, in the schools, 23; diseases of, jequirity in, 766; findings, and longevity, 1170; pain connected with, 491; pressure within, physiology of, 26; significance of choked disk of, 217; strain of, see eyestrain.
Eyelids, edema of, 213.
Eyestrain, 685.

Horwitt, S., report of a case of complete transposition of the viscera, 1170.
Hospital, and dispensary abuse, 546; infants' summer, report from, 960; noise, 114; prophylaxis, 949; service in, in Germany and the United States, 571; Hospital, the Ancon, 29.
Hospitals, for children, 411; value of fresh air in, 1021; modern, 487; of England, effect of insurance act on, 671.
Humerus, fracture of, ununited, in obese subject, 1101.
Hunt, E. L., sciatica and its treatment, 1153.
Hydrocele, flashlight in diagnosis of, 449; in infants, operative treatment of, 491.
Hydrochloric acid of stomach, influence of sodium chloride on, 155.
Hydronephrosis, 120, 1006; containing twelve quarts, 641.
Hydrophobia, see rabies.
Hygiene for the normal child, 199.
Hypertension, clinical aspects of, 1194; significance and management of, 798.
Hypnotism, public exhibition of, forbidden, 1008.
Hypophysis and diabetes insipidus, 309; disease of, some new aspects of, 576; extract, for and against, 123; extract in eclampsia, 32, 1181; extract of, in surgical shock, 995; extract plus galvanization in the induction of abortion, 668; surgery of, 362; tumor of brain immediately behind, 637.
Hypopituitarism, 551.
Hysterectomy, including left salpingo-oophorectomy, 640; vaginal, hemisection of the uterus, and a method of preventing cystocele, 640; vaginal, morcellement and clamp method, 641; vaginal, with amputation of the uterus at the internal os, 640.
Hysteria, a comparison of Plato's and of Freud's theories of, 905.

## I

Idiocy, congenital, complement fixation reaction in, 1000.
Ileocecal valve, in competency of, 1105.
Ileocolitis, nature of, from an etiological standpoint, 1188.
Ileum, acute invagination of, secondary to sarcoma of small intestine, 228; fecal impaction of, 539; kink of, pericecal membrane and cecal mobility, etiology of, 179.
Ileus, 176, 539; acute, 1090; due to gallstones, 173, 1134; spastic paralytic, 811.
Immigration of insane and defectives, 114.
Immunity inefficient and new growth, 354.
Indicanuria and the phosphates, 297.
Industry, diseases of, reporting of, 867.
Infancy, emotional grimaces of, 172.
Infant, feeding, 538, 916; feeding, artificial, etiology of, 1192; feeding from a new standpoint, 916; feeding, some observations on, 915; feeding, goat's milk as compared with cow's milk in, 916; feeding in relation to infant mortality, 87; feeding with undiluted cow's milk, 915; mortality, see mortality.
Infantilism, a case of, with pronounced dysarthroidal features, 681.
Infection, aerial and contact, 113; and digestion, 1000; bacterial, as carried by insects, 171; mucous channels and the bloodstream as alternative routes of, 723.
Infectious diseases, ear complications of, 397; general management of, 910.
Influenza, an ancient epidemic of, 632.
Inheritance of acquired qualities, 122.
Injury, a typical street railway, 79; evidence as to permanency of, 20; recent, treated by mobilization and massage, 391.
Insane, and defectives, immigration of, 114; sterilization of the, 1138; the "recovered," the menace of, 565.
Insanity, Abderhalden's serodiagnosis in, 1180; among aliens, 949; and epilepsy in ancient times, 184; and the neuropathic inheritance, 481; curability of, 942; in kings, 184; manic-depressive, and literary genius, 245; some of the common forms of, 707; Wassermann reaction in, 720.
Insects as carriers of bacteria, 171, 214.
Insurance and eugenics, 1182; application, interpretation of word "illness" in, 297; companies, in working for a decreased mortality, 911; interest, 311; life, see life insurance; national, in England, 117, 442, 703; national, in England, and its effect on hospitals, 671; national, in England, crisis of, 25, 210; national, in England, difficulties of, 167; nattional, in England, opposition against, 303; national, in England, pledge for, rescinded, 302; physicians, union of, in Berlin, 810; workingman's, 543.
Interest rate in life insurance, 494.
Interne year, the, 1043.
Intestine, autointoxication of, 928; bacteria of, producing ptomaines, 491; bacteriological study of, in nurslings, 1138; disease of, hog as a carrier of, 947; experimental devascularization of, 319; intoxication from, 262; intoxication from and polyneuritis, 171; movements of, local action of lead upon, 827; obstruction of, see ileus; small, new instruments for, 1119; small, sarcoma of, causing acute invagination of the ileum, 228; stasis of, 252; stasis of, chronic, 78, 117, 909, 999; stasis of, treated with liquid petroleum, 1172.
Intoxication, enterogenous, 262.
Intussusception, 359, 999; Henoch's purpura with, 723; in an adult, 1100; progress in diagnosis and treatment of, 766.
Iodine, in treatment of infections, 228; vaporization in therapeutics, 1012.
Iritis, etiology of, 341.
Isham, M. K., a paranoid state, 1121.

## J.

Jackson's membrane, 1042; and the fetal peritoneal folds of Jonnesco, Treves, and Reid, 179.
Jacoby, G. W., the Montessori method from a physician's viewpoint, 691.
Japan, portrayal of the blind in, 598.
Jaundice, acholuric, following splenectomy, 1181; acquired splenomegalic hemolytic, 777; epidemic catarrhal, 298; hemolytic, 910.
Jaw, upper, acute osteomyelitis of, 111.
Jelliffe, S. E., a summary of the origins, transformations, and present-day trends of the paranoia concept, 599.
Jequirity in ophthalmic work, 766.
Jews, psychopathology of, 666.
Johnson, Doctor, and the doctors, 92.
Joints, fractures into and about, 177; inflammation of, see arthritis.
Josephson, J. C., erysipelas complicating measles, 395.
Julian, C. A., observations of results from vaccination against tuberculosis, 1059.

## K.

Kahn, M. H., postmortem ophthalmoscopy: segmentary intravascular coagulation, 801.
Kellogg, J. H., incompetency of the ileocecal valve, 1105.

Kidney, acute hematogenous infection of, 319; Ambard's method of estimating functional value of, 252, 1064, 1088; and eclampsia, 622; and ureter, calculi of, 169; calculi of, and pyelotomy, 360; calculi of, diagnosis and treatment of, 320; calculus of, in childhood, 262; disorders of, a method of classification, diagnosis, and therapy of, based on functional testing, 699; functional capacity of, 913; functional capacity of, and cryoscopy, 214; functional capacity of, and its bearing on treatment, 913; functional capacity of, and its prognostic value, 913; functional diagnosis of, 310; hematoma surrounding, following scarlatina, 217; insufficiency of, and mental symptoms, 445; insufficiency of, as determined by Ambard's method, 252, 1064, 1088; involvement of, in pulmonary tuberculosis, 870; lithiasis of, 269; medical disorders of, recent French progress in, 15; retention of foreign protein by, 389; stone in, bilateral, 1006; subcutaneous rupture of, 64; suprarenals, and testicle, tumors of, embryogenic relationships of, 318; surgery of the single, and the horseshoe, 320; symmetrical cortical necrosis of, in puerperal eclampsia, 998; test of functional capacity of, by means of chromoureterscopy, 213; tuberculosis of, 589; tuberculosis of, a new method of diagnosing, 590; tuberculosis of, specimens of, 591; tumors of, 400; unilateral lesions of, 580; washing pelvis of, with collargol, 395.
King, W. H., intestinal autointoxication, 928.
Kings, madness of, 184.
Kink, ileal, etiology of, 179.
Kitchen, J. M. W., atmospheric devitalizing influences, 167.
Kosmak, G. W., radical and conservative methods in obstetric treatment, 514.
Knee, ankylosis of, arthroplasty for, 589.
Knopf, S. A., some newer problems and some newer phases of the antituberculosis warfare in the United States, 186.

L

Labor, see parturition, 766.
Labyrinth, diseases of the, 56; vertigo of, caused by local autogenous temperature variations, 1125.
Lactation and the nervous system, 958.
Lactic acid bacilli, efficacy of, in diabetes, 142.
Landry's paralysis, 729.
Lane's kink, 179.
Laparotomy, exploratory, a plea for early, 872; early, a plea for, 981.
Laryngoscopy, suspension, 120, 329.
Larynx, and trachea, treatment of chronic stenosis of, 1042; congenital membrane of, 1047; speech without a, 1044; stenosis of, following diphtheria, treatment of, 1042; tuberculosis of, cauterization in, 213.
Lead poisoning in the brass industry, 632.
Lecithin, and cholin as antituberculous remedies, 861; cholesterin and the growth of tumors, 827.
Leg, chronic ulcer of, fuchsin in the treatment of, 1090; reflex, a new, 78.
Legend, the growth of a, 46.
Leopold, S., gradually developing hemiplegia due to a cerebral neoplasm, 527.
Leprosy, bacilli in the blood, 448; segregation of victims of, 765; yaws mistaken for, 765.
Leszynsky, W. M., sexual disorders, association with disease of the nervous system, and remarks on present-day sexual problems, 661.
Leucemia, benzol in, 398, 823.
Leucocyte counts in epidemic meningitis and pneumonia, 1191.
Lewinski-Corwin, E. H., the associated out-patient clinics of the City of New York, a social force, 294.
Liability of corporation for physician's services, 665.
Libraries, medical, 497.
License, medical, revocation of, a very bad bill relative to, 713; osteopathic, revocation of, 413; practising without, 896; revocation of, 480; to practice, 480.
Lids, edema of, 213.
Life, expectation of, in surgical conditions of the abdomen, 605.
Life insurance, accident and apoplexy in, 218; and albuminuria, 264, 312, 634; and carious teeth, 174; and faith cure, 356; and heart murmurs, 911; and rated-up lives, 264; and suppression of avoidable mortality, 174; and the local medical examiner, 816; and tuberculosis, 1094; application, the, 124; companies, 35; companies as affected by conservation of life, 174; company as a force in the movement for physical welfare, 1002; early, 816; elementary principles of, 404, 770, 862; examiners, see examiners; examinations and diabetes mellitus, 312; examinations, points to insure honesty in, 725; examinations, prevention of fraud in, 915; limit of, in children, 1002; medical considerations in, 816; medical inspection for, 35; misrepresentations as to health in application for, 574; more careful examinations required in, 911; of the future, 125; overweight in, 634; policy, 218; premiums in, 678; prevention of fraud in, 678; principles of, 494; prognostic significance of albumin and casts in, 543; proofs of death in, 530; the reserve in, 770; uranalysis in, 725.
Ligature and suture material, 767; surgical, the, 598.
Lightning, death by, 676; stroke by, 580.
Lime starvation, treatment of, 517.
Lipodystrophia, progressiva, 1136.
Lipoid metabolism in developing chick, 160.
Lipoids, rôle of, in narcosis, 449.
Liquor obtained on prescription, 20.
Lister, Godlee's oration on, 628.
Lithiasis, urethral, 538.
Liver, disease of, and chloroform anesthesia, 633; galactose test of, function of, 594; pancreas, and carbohydrate metabolism, 541; primary adenomata of, 460; solitary cyst of, 229; syphilis of, fatal hematemesis in, 585; tuberculosis of, with jaundice, 950.
Lives, rated-up, statistics of, 264.
Löbker, Carl, death of, 488.
Lobsenz, J. M., angioneurotic edema, 975.
Longevity and ocular findings, 1179.
Luetin reaction, 384, 1178.
Lumbar puncture, a plea for the more frequent use of, 960; in the treatment of headaches, 322.
Lung, abscess of, chronic, cured by artificial pneumothorax, 89; emphysema of, surgical treatment of, 590; lesions of, and non-virulent pneumococci, 633; osteoarthropathy associated with disease of, 155; pneumococcal abscess of, in children, 860; pneumo-coccal infection of, chronic, in children, 1136.
Lupus erythematosus, treatment of, 1104; vulgaris following measles, 619.
Lusk, G., the newer opinions concerning diabetes mellitus (translation from O. Minkowski), 220.
Lymphatic gland, extracts in treatment of enlarged tonsils and adenoids, 1137; mediastinal, rupture of, into bronchus, 1186.
Lymphatics, circulation in, and Asellius, 398; and gastric ulcer, 677; blood picture of, 851.
Lymphuria, the clinical evidence of, 967.
Lynch, J. M., a preliminary report of operations under extradural anesthesia, 235.

M.

McCord, C. P., rationale of the use of ademalin in the treatment of asthma, 431.
McMurtrie, D. C., prostitution in New York City, a study in social hygiene, 970.
M'Kinniss, C. R., epilepsy, 749.
Maimonides, a great physician of the Middle Ages, 230.
Malaria, in Jerusalem, warfare against, 814; mosquito origin of, 1092; pernicious, 397.
Malingering and valetudinorianism, 908; in accident and disease, 543.
Malnutrition, infantile, 305.
Malpractice, acts constituting, 757; and instructions by jury, 757; non-expert evidence as to, 574.
Mandlebaum, F. S., inflation of statistics, 117.
Mandible, a serous cyst evacuated through the ramus of, 815.
Manganese, poisoning, 490.
Manila, mortality in, 672.
Mannheimer, G., preliminary report of personal experiences with the Friedmann treatment of tuberculosis, 1030.
Manning, J. Van V., a study of flaccid paralysis which attacked Louis Pasteur in early maturity and its similarity to an attack of acute epidemic poliomyelitis; together with a study of the silkworm as a possible mediary host of the same disease, 976.
Marriage license bill, the proposed, 851.
Mason, R., acids in the treatment of cancer, 1175.
Mastoid, operation, clinical indications for, 685; operation, combined laboratory and *x*-ray indications for, 686; wound, postoperative, tibial bone transplantation in, 372.
Materia medica, the new, and the new chemistry, 248.

Maus, L. M., the effects of the beerless exchange on the morals and health of our soldiers, 332.

Maverick, A., blunders made by nature; the part played by nature in causing disease of the digestive and nervous systems, 613; blunders made by nature; the part played by nature in causing disease of the genitourinary organs and the skeleton, 931.

Mays, T. J., the action and administration of crotalin in pulmonary consumption and in epilepsy, 56.

Mead, F., faith cure and insurance, 356.

Mead, F. H., scarlet fever, is the desquamatory stage contagious, 293.

Measles, multiple lupus vulgaris following, 619.

Mediastinum, tumor of, 552; tumors of, early signs of, 78.

Medical Society of the County of New York, inaugural address of the president-elect of, 455.

Medical Society of the State of New York: General sessions, 820; report of the committee on prize essays, 819; report of the committee on scientific work, 819; report of the committee on experimental medicine, 819; report of the committee on legislation, 819; report of the committee on public health, 818; report of the committee on publication appointed by the council, 818; report of the committee on the regulation of the introduction of expert testimony, 819; report of the committee on revision of by-laws, 819; report of the council, 818; report of the counsel, 819; report of the president, 818; report of the secretary, 818; report of the treasurer, 818.

Medicine, Academy of, work and needs of, 139; activities of, in Russia, 805; and experimental psychology, 237; and liberty, 215; authority to practise, 436; bibliographic style in literature of, 157; certain elementary concepts in education applied to, 875; cinematrograph in, 77; enthusiasm in, 230; errors in the practice of, 782; esthetics of, 723; ethics of, 859; operative surgery in the general practice of, 349; popular education in, heresies in, 713; practice of, requirements for in Germany and the United States, 571; profession of, in Germany, statistics relating to, 719; tropical, 257, 670; Vienna as a center for postgraduate study in, 721.

Membrane, Jackson's, 179, 1042.

Memory, weakness of, treatment of, 123.

Meninges, tumor of extirpated with local anesthesia, 633.

Meningitis, atypical forms of, 1191; epidemic, 629; epidemic, in children under two years, 1134; epidemic, leucocyte counts in, 1191; epidemic, serum treatment of, 988; influenzal and pneumonia, 1043; influenzal, with recovery, 1098; irrigation of spinal canal in, 584; pneumococcus, 674; serum against, a danger in the use of, 907; staphylococcus, in a child, 1187; tuberculous, cerebrospinal fluid in, 1138; tuberculous, glycosuria in, 172; vaccination against, 859.

Menopause, the, puberty and neurasthenia, 722.

Menstruation, disturbances of, tuberculous etiology of, 263; precocious, 1191.

Mercury, and sulphur in the treatment of pneumonia, 1097; bichloride of, poisoning caused by, 501; in treatment of diseases of vegetable parasitic origin, 323; intravenous injections of, and their influence upon antibody formation, 897; versus salvarsan, 76.

Metabolism, fat, and the suprarenal capsules, 724; lipoid, in developing chick, 160.

Metastasis, superficial growths caused by, 213.

Meyer, W., the surgical treatment of cancer of the esophagus, 888.

*Micrococcus tetragenus* septicemia, 1058.

Micrograph, Crehore's, compared with Jacquet's sphygmograph, 1194.

Midwife, necessity of, 628.

Midwifery, see obstetrics.

Migraine, gouty, treatment of, 828.

Milk, and cream, grading of, 1127, barn operations, and germ content of, 1193; boiled and raw, 446; certified, 1193; commission, efficiency of, 1193; goat's, as compared with cow's, in infant feeding, 916; pasteurized, nutritive effects of, 898; protection of, 1089; protein, as a means of correcting digestive disturbances, 315.

Miller, M. B., surgical conditions of the abdomen in their relation to life expectation, 605.

Milne, L. S., a case of Addison's disease with severe abdominal symptoms, 974.

Mind, defective, see defectives, mental; deficiency of, early diagnosis of, 1190; feebleness of, effect of pineal gland extract on, 835; inferiority of, 533; tests of efficiency of, 1, 37.

Miners, myostagmus of, and working capacity, 540.

Minkowski, O., the newer opinions concerning diabetes mellitus (translated by Graham Lusk), 220.

Mittendorf, W. K., gonorrheal ophthalmia, treated with vaccines, 428.

Mnemasthenia, treatment of, 123.

Mongolism and ancestral affinities, 390.

Montessori method from a physician's viewpoint, 691.

Morgan, J. D., Hodgkin's disease, 292.

Morris, R. T., a short-circuit warning, 993; peritoneal adhesions of the insidious toxic group, 645.

Morse, C. F., the Ancon Hospital, 29.

Morphine, intolerance of children to, 263; withdrawal, scopolamine in, 953.

Mortality, among physicians, 437; decrease of, as brought about by insurance companies, 911; diminution of, and life insurance, 174; in Manila, 672; in middle life and old age, upward trend of, 450; infant, 850; infant, certain neglected aspects of, 918; infant, in relation to infant feeding, 87.

Morton, H. H., the self-limitation of gonorrhea, 670.

Motorist, dangers to, in weak bridges, 414.

Mould fungi, poisoning by, 677.

Mouth, and pharynx, cancer of, surgery of, 907; and teeth, and alimentary toxemia, 898; and tongue, cancer of, 461; and tongue, malignant disease of, 500; breathing following adenectomies, 397; neglect of treatment of, in infectious diseases, 250; sepsis from, an unusual case of, 89.

Mucocele of anterior ethmoidal cells, 31.

Mucous channels, and blood stream as alternative routes of infection, 723.

Mulot, O. L., a new treatment for acute gonorrhea, 709.

Mumps, tonticollis following and associated with cervical ribs, 664.

Murmur, an unusual, 551.

Muscle, application of, for physiological standardization, 1097; atrophy, following fracture-dislocation of cervical vertebræ, 680; atrophy of, simulating that of amyotrophic lateral sclerosis, 1049; atrophy of, syphilitic, 1051; progressive dystrophy of, relation of syphilis to, 1033.

Myasthenia gravis, 85, 865.

Mycetoma, 907.

Myocarditis, pain and other clinical manifestations of, 828.

Myocardium, signs of, involvement of, 585.

N

Nail, travels of, in alimentary canal, 906.

Nammack, C. E., salvarsan in cryptogenetic pernicious anemia, 847; the differential diagnosis of lobar pneumonia, 611.

Napoleon, death of, and alleged specimens relating to, 212; military surgery in the time of, 1172.

Narcolepsy, 448.

Narcosis, rôle of lipoids in, 448.

Nasopharynx, of a child, cystic polypus in, 849.

Nature, blunders made by, in treating disease, 613, 931.

Negri bodies, and the virus of rabies, 897; practical value of, from diagnostic standpoint, 406.

Negro, venereal diseases in, 983.

Neosalvarsan, experience with, 502; experience with, at the Harlem Hospital, 868; in syphilis of the nervous system, 1097; subarachnoid injections of, in treatment of, cerebrospinal syphilis, 1012.

Nephritis, chronic, anemia in, 906; chronic, periodical protein-free diet in, 1042; chronic, prognosis of, 577; chronic, unilateral hematuria in, 305; following tonsillitis, 113; hepatitis, and myocarditis of, syphilitic origin, 551; internal treatment of, 906; treatment of, 1090.

Nephrolithiasis, bilateral, 1006.

Nervous and mental diseases, cinematograph demonstration of, 183.

Nervous system, and lactation, 958; diseases of, blunders made by nature in causing, 613; diseases of, sexual disorders associated with, 661; internal secretions and, 586; peripheral, and pulmonary tuberculosis, 306.

Neuralgia, pathology of, 766.

Neurasthenia, puberty and the menopause, 722; senile, treatment of, 828.
Neuritis, brachial plexus, metapneumonic, 403.
Neuroma, acoustic, 413.
Neuroses, folk, 23; Jung's modification of the Freudian theory of, 375; occupation, 464.

Pearson, C. B., a plea for greater consideration for the opium addict, 342.
Pediatrics, social, 918.
Pellagra, 169, 951; a case of, 55; *Diplodia zeæ* and, 629; experimental production of lesions resembling, 672; immunity reaction in, 205; metabolism in, 593; possible causation of, 260; prevalence and distribution of, 592.
Pelvis, inflammation in, autoinoculation treatment of, 260.
Pemphigus malignans cured by single intravenous injection of blood, 999.
Percussion, and auscultation, 584; dorsal, in the diagnosis of appendicitis, 112.
Pericarditis in infancy, 1080.
Pericolitis, 261; membranous, 728; membranous appendicitis and mucous colitis, correlation of, 180.
Periodontal disease, pathology of, 860.
Peritoneum, adhesions of, 1099; adhesions of, of the insidious toxic group, 645; adhesions of, short circuit operation in, 901; application of oil to, 815; fetal folds of, and relationship to Jackson's membrane and Lane's kink, 179.
Peritonitis, diffuse purulent, from diverticultis, 173; fatal, following use of a laminaria tent, 1000; gallbladder, without perforation, 33.
Pertussis, treatment of, 322; vaccine therapy of, 259, 344.
Petroleum, liquid, in the treatment of intestinal stasis, 1172.
Pfender, C. A., Barlow's disease in an infant fed on Pasteurized cow's milk, 704.
Pharmacology, recent research in, 1135.
Pharmacopœia, United States, absurdities of the ninth decennial revision of, 1006.
Pharmacotherapy of pneumonia, 31.
Phenol, in prevention of uric acid, 86.
Phenolsulphonephthalein, in clinical medicine, 552.
Phlebotomy, bloodless, 550.
Phlegmon, ligneous, of abdominal wall, 721.
Phosphorus in epilepsy, 677.
Photography, natural color, and forensic medicine, 1128.
Physician, and pharmacist and sale of liquor, 378; and morals, 1041; employment of, 297; employment of, implied authority of agent for, 665; mortality of, 437; services of, liability of corporation for, 665; the physician's selection of his own, 625.
Pilcher, J. T., postoperative gastroenteric paresis, 378.
Pilocarpine and atropine, action of, on the urinary secretion, 542.
Pineal gland, the functions of, 835.
Pinel, T., the pathogenesis of the gastric crises of tabes, 783.
Place, F., bibliographic style in medical literature, 157.
Placenta previa, anatomical basis of, and its relationship to therapy, 1047.
Plague, banners, 966; in Iloilo, 27; in Manila, 27; in Manila, bacteriological observations made during, 27; in the Philippines, 351, 396, 1132; pneumonia in Brazil, 34.
Plagues, world, present status of, 667.
Pleura, effusions of, completely removed with oxygen replacements, 121.
Pleurisy, serafibrinous, autoserotherapy in, 674.
Plexus, brachial, supraclavicular anesthetization of, 492.
Pneumococcus, causing acute vascular lesions, 310; infections, pharmacotherapy of, 77; infections of the lungs in children, 1136; meningitis, 674; non-virulent, and pulmonic lesions, 633; pulmonary abscess due to, in children, 860.
Pneumonia, acute, occurring during treatment with arsenic, 448; and appendicitis, differential diagnosis between, 567; camphor in the treatment of, 1036; clinical study of 1179; experimental, studies in, 732; from the laboratory viewpoint, 1008; leucocyte counts in, 1191; lobar blood, and sputum in, 583; lobar, the differential diagnosis of, 611; lobar, sputum and blood cultures in, 594; pharmacotherapy of, 31; plague, in Brazil, 34; quinine treatment of, 1097; the perennial problems of 68; treated with mercury and sulphur internally, 1097; treatment of, 766.
Pneumothorax, artificial, 591; artificial, indications and contraindications, 591; artificial, technique, and results, 592; treatment of phthisis, 31.
Poisoning, non-corrosive, adrenalin in the treatment of, 400.
Policy, the life insurance, 218; values, annual statement of, 954.
Polk, W. M., work and needs of the Academy of Medicine, 139.
Pollitzer, S., the passing of parasyphilis, 797.
Polycythemia, 813; secondary in cardio-pulmonary cases, 999.
Polygraph, the, 869.
Polioencephalitis, 406.
Poliomyelitis, a preparalytic symptom of, 584; and variola, 766; carriers, 214; causation of, 263; cultivation of virus of, 306; experimental, 491; length of incubation period of, 677; shoulders and arm paralyses of, 905; silkworm as a possible mediary host in, 976; the painful symptoms of, 111; transmission of, 1044.
Polymyositis, with multiple lime deposits, 1052.
Polyneuritis and intoxication from intestine, 171.
Polypus, cystic, in nasopharynx of a child, 849.
Posture, upright, in man, 537; upright, influence of, upon mankind, 942.
Potence, rare disturbance of, 1138.
Pott's disease, Hibb's operation for, 684.
Pregnancy, Abderhalden's reaction in, and the internal secretions, 1000; abdominal, with living child, 228; and tuberculosis, 985; albuminuria in, significance of, 1044; bilateral and multiple ectopic, 1135; biological diagnosis of, 677, 1093; cholecystitis and cholelithiasis of, 949; convulsions in, conservative treatment of, 582; corpus luteum and, 1046; ectopic, case of, with slight hematocele, 639; ectopic cyst of corpus luteum resembling, 181;

ectopic, with large hematocele, 639; ectopic, with unusual features, 641; extrauterine, 228; galvanic neuromuscular excitability in, 953; in uterus unicornis, 362; interstitial, ruptured, 225; labor, and puerperium, tuberculosis, in relation to, 182; ruptured tubal, transfusion in treatment of, 444; serodiagnosis of, 769; toxemia of, a new method of treating, 66; toxemia of, cured by Ringer's fluid, 402; toxemia of, oxygen in, 166, 210.

Prevention versus cure, 909.

Prisms, their use and equivalents, by J. Thorington, 912.

Prison, sentences for young girls, results of, 217.

Proctoclysis, an experimental study of, 227.

Progeria and ateleiosis, 345.

Proof, burden of, 987.

Prostate, carcinoma of, suprapubic cystostomy in, 673; hypertrophy of, 996; remote effect of lesions in, 1146; removal of, with reference to the sequels, 318.

Prostatectomy, air embolism following, 719.

Prostitution, essential cause of, 620; in New York City, 970; regulation of, in San Francisco, 467.

Protein, assimilation, 731; element in nutrition, 344; milk, as a means of correcting digestive disturbances, 315; poison, and its relation to disease, 1188.

Protozoa finds in swimmers' conjunctivitis, 310.

Pruritus, local applications in, 46.

Psoriasis, treatment of, 34, 138.

Psychanalysis, nature of, 737.

Psychiatry, Abderhalden's serodiagnosis in, 1180.

Psychology, clinic of, 961; clinics of, in the public schools, 733; experimental, and medicine, 237; genetic, 962.

Psychoneuroses, therapy of, 122.

Psychopathology, racial, 666.

Psychoses, and Abderhalden's dialysis procedure, 493.

Psychotherapy, principles of, 80.

Ptomaines produced by intestinal bacteria, 491.

Ptosis, abdominal, exercises in treatment of, 490; rôle of, in gynecology, 119; visceral, and arthritis, 537.

Puberty, the menopause and neurasthenia, 722.

Publicity, and cancer of the uterus, 674.

Puerperium, eclampsia of, see eclampsia; sepsis of, total gangrene of breast in, 33; the management of, 752.

Pulmonary tuberculosis, abortive, 921; advanced, value of treatment in, 1099; albumin reaction in the sputum of, 354; and peripheral nervous system, 306; and the teeth, 206; artificial pneumothorax for the relief of advanced, 1148; as influenced by the climatic conditions of California, 1099; blood pressure in, at high altitudes, 1149; compulsory detention of the homeless afflicted with, 934; control of the careless victim of, 1089; crotalin in, 561; early diagnosis of, 735; Friedmann treatment of, see Friedmann, F. F.; incidence of, renal involvement in, 870; incipient, gastric symptoms in, 312; infection from an attendant with, 1044; pneumothorax treatment of, 31; prognosis of, and Arneth's method, 952; rest and repair in, 1149; seasonal variation of, 629; the albumin reaction of the sputum in the diagnosis of, 746; the blood in, 812; the sanatorium in the home in the treatment of, 153; treated with mixed bacterins, 824; treatment of, by means of class method, 119; treatment of hopeless cases of, 583.

Pulmotor, the infant, 181.

Pulse, deficit in auricular fibrillation, 90; pressure, high and low auscultatory, 1194.

Purgatives, study of, with the technique of intestinal perfusion, 1047.

Purpura, chronic, of infancy, treatment of, 322; Henoch's, with intussusception, 723.

Pylephlebitis, suppurative, 229; suppurative, treatment of, 590.

Pylorospasm, duodenal catheter in the study of, 586.

Pylorus, spasm and stenosis of, 170; ulcer of, chronic, diagnosis and treatment of, 1046.

Pyocyaneus bacillus, general infection with, 123.

Pyorrhea alveolaris, treatment of, 29.

Pyosalpinx, double, of large size, 225.

Pyuria, intermittent, 722.

Q

Quadruplets, 910.

Quarantine, in the maritime cities of the United States, 469; nationalization of, 161.

Quinine, derivatives in anesthesia of cornea, 541; total deafness following dose of, 1043; treatment of lobar and lobular pneumonia, 1097.

R

Rabies, and rodents, 444; an early symptom in, 721; diagnostic value of Negri bodies in, 456; etiology of, 815; virus of, and the Negri bodies, 897.

Race, psychopathology of, 666.

Rachitis, 217; action of phosphorized oil in, 910; nature of, 403; reaction, biochemical, active principle in, 586.

Radioactivity and vegetation, 444.

Radium, action of, upon blood and upon arterial pressure, 987; and cancer research, 1175; and the Middlesex Hospital, 1131; and thorium-*x*, therapy, 95; and *x*-rays and their influence on deep-seated cancer, 493; emanation therapy, 951; in surgery, 872; Institute, report of, 308; treatment of cancer, 1179.

Radius and ulna, congenital displacement of upper ends of, 665.

Rankin, E. G., the compulsory detention of the homeless tuberculous, 934.

Rawls, R. M., cancer of the uterus, 892.

Rectum, electricity in diseases of, 858; feeding by way of, 262; surgery of, under local anesthesia, 858; surgery of, use of formalin in, 1012.

Reid, E. C., literary genius and manic-depressive insanity with special reference to the alleged case of Dean Swift, 245.

Relapsing fever in Persia, 586.

Remedies, new, of the past year, 814.

Research, defense of, 580.

Respiration, action of suprarenal extract upon, 968; artificial devices for, 731, 950; artificial, in infants, and the infant pulmotor, 181.

Restitutio ad integrum after severe diseases of childhood, 391.

Retina, changes in, in adolescence, 315; segmentary coagulation in the vessels of, post-mortem, 801; significance of choked disk of, 217.

Reuben, M. S., the inflation, statistics, 256.

Rheumatism, 730; gonorrheal, in arthritic subjects, 150; salicylic acid and allied bodies in, 675.

"Rheumatoses" of nasal origin, 943.

Rhinitis, atrophic, and ozena, treatment of, 1090; posterior, in nurslings, 1092.

Rhodium, colloidal, therapeutic value of, 92.

Ribs, cervical, 580; cervical, associated with torticollis following mumps, 664.

Rice, polished, tax on, 765.

Rickets, see rachitis.

Rinne test, prognostic value of, 103.

Ritter, J., the albumin analysis of the sputum, its great value as a reliable and positive diagnostic laboratory method for differentiating pulmonary tuberculosis from other pulmonary diseases, 746.

Rob, the, 1021.

Robbins, F. C., report of a case of pellagra, 55.

Robinson, B., the medical treatment of appendicitis, 530.

Rockey, A. E., a short-circuit warning, 901.

Rolph, F. W., the dissolved albumin test for gastric cancer, 848.

Rosenberg, L., the sanatorium in the home, 153.

Rosenstirn, J., the municipal clinic of San Francisco, 467.

Roseola infantum, 1191.

Rötheln, blood count in differentiation of, from measles, 1181.

Royal College of Surgeons, Museum of, 486.

Rush, J. O., venereal diseases in the negro, with special reference to gonorrhea, 983.

Rueck, G. A., a fatal case of gonococcus septicemia, 18.

Russell, J. F., the treatment of lime starvation, 517.

Russia, medical activities in, 805.

Rytina, A. G., the luetin skin test in the diagnosis of syphilis, 384.

S

Sabella, N., use of the fetal membranes in skin grafting, 478.

Sacrum, ventral tumors of, 360.

Salicylates, toxicity of, 674.

Salicylic acid and allied bodies in rheumatism, 675.
Salvarsan, in cryptogenetic pernicious anemia, 847; in malignant precocious syphilis, 868; in pernicious anemia, 32, 215, 1091; in syphilis,, 354; in Vincent's angina, 644; neo-, see neosalvarsan; treatment, dangers of, 1091; treatment of a case of Graves' disease with sclerodemia, 1124; treatment of frambesia, 1127; versus mercury, 76.
Sanatorium, and the public health, 1128; or the home, 153.
San Francisco, municipal clinic of, 467.
Sanitation, at Panama, 914; municipal, early days of, 1035.
Sarcoma fowl and its filterable virus, 815; melanatic, 306.
Scarlet fever, and appendicitis, 676; benign, 1127; contagiosity of desquamatory stage, 298; inclusion bodies in, 299; perirenal hematoma following, 217; relapse in, 1047; symptomatic, 715.
Scarlet-red action of, upon *x*-rayed skin, 447; in treatment of gastric and duodenal ulcer, 1099.
*Schistosomum japonicum*, 1132.
School, children, use of snuff and tobacco by, 1173; public, needs of psychological clinics in, 733; routine disinfection of, 398; seating and scoliosis, 312, 398; value of fresh air in, 1013.
Schwaback test, prognostic value of, 103.
Sciatica and its treatment, 1153.
Scoliosis and school seating, 312, 398; treatment of, 486.
Scopolamine, in morphine withdrawal, 953.
Scripture, E. W., the care of speech defectives, 339; what is psychanalysis, 737.
Scurvy, infantile, at the school age, 401; infantile, in an infant fed on pasteurized cow's milk, 704.
Secretions, internal, and osteomalacia, 299; internal, and the nervous system, 586; internal, in relation to dermatology, 1045; internal, nonspecificity of diseases due to, 206.
Sepsis, oral, 89; *Staphylococcus aureus*, a series of cases of, 90.
Septicemia, gonococcus, a fatal case of, 18.
Septicopyemia, a case of acute, 711.
Serotherapy, and chemotherapy, 439; in hemorrhage of newborn, 216.
Services, medical, township's liability for, 276; medical, promise to pay for, 276; medical, recovery for, as damages, 803.
Sewerage problem in New York City, 409.
Sex, diseases of, see sexual diseases; education as to, 989; ethics, 259; problems of, present day, 661.
Sexton, L., surgical tuberculosis, 618.
Sexual diseases, associated with disease of the nervous system, 661.
Shears, G. P., a new method of treating the toxemia of pregnancy, 66; oxygen in the toxemia of pregnancy, 210.
Sheedy, B. DeF., the results of tonsillectomy, 654.
Sheffield, H. B., inflation of statistics, 166; inflation of statistics as emphasized by a recent report in primary splenomegaly, 74.
Shock, causation of, 258.
Shock, therapy of, 359.
Shoes, well-fitting, for the army, 898.
Short-circuit operation in peritoneal adhesions, 901.
Shoulder, subluxation of, with birth paralysis, 951.
Sialoadenitis sublingualis acuta epidemica, 667.
Sicard, M. H., further experience with the high calory diet in typhoid fever, 523.

Syphilis, a secret remedy for, the "rob," 1021; agglutination in, 298; and the surgical out-patient, 720; cancer of tongue and its relation to, 768; causing nephritis myocarditis and hepatitis, 551; cerebrospinal, subarachnoid injections of neosalvarsan in, 1012; congenital and eczema on, 722; congenital, and mental disease, 263; dispensary facilities for the treatment of, 452; distilled water in the treatment of, 768; heart in, 821; neosalvarsan in, see neosalvarsan; obligations of physicians regarding, 869; of the nervous system, neosalvarsan in, 1097; pernicious anemia due to, 1180; precocious malignant, salvarsan in, 868; present status of the treatment of, 769; pulmonary, 1098; relation of, to internal medicine, 454; relation of, to progressive muscular dystrophy, 1033; salvarsan in, see salvarsan; the luetin skin test in the diagnosis of, 384, 1178; treatment of, 1080; unusual fertility in parents with, 909.
Systoles, extra, 583.

## T.

Tabes, juvenile, 84; pain in, 445; the pathogenesis of the gastric crises of, 783; treated with arsenic and bacterial preparations.
Tapeworm, dwarf, infection with, 537; human, and cysticercus in domestic animals, 443.
Tattooing, erysipelas and, 1047.
Teeth, and mouth in relation to alimentary toxemia, 898; and pulmonary tuberculosis, 206; bad, and disease, 439; care of, in German army, 216; carious, and life insurance, 174.
Testimony, expert, 987; expert, as to mental capacity, 987; medical expert, 577; medical expert, report of committee on, 820.
Tetanus, prophylactic serotherapy of, 632.
Tetany in acute suppurative appendicitis, 909.
Therapeutics, drug, foundations of, 216; of gastrointestinal tract, 216; the dilemma in, and its psychological basis, 531.
Thirst cures in chronic bronchial affections, 263.
Thompson, W. G., dentenarians and nonagenarians, 277; osteitis deformans, 832.
Thoracotomy for pulmonary embolism, 1128.
Thorax, opening of, for pulmonary embolism, 1128; surgery of, 280.
Thorium, chloride in animal cancer; *x* and radium therapy, 95.
Throat, septic sore, epidemics of, 22.
Thromboangeitis obliterans of Buerger, 261.
Thrombophlebitis, of external iliac vein, 997.
Thymus, death and thymic tracheostenosis, 446; hyperplasia of, 171.
Thyreosis and tuberculosis, 402.
Thyroid, the, and alimentary toxemia, 1045, and disease of the uterus, 1047; coexisting infection and sarcoma of, 363; surgery of, 584, 630; treatment of epilepsy, 322; tuberculosis of, 483; tumor, aberrant, from base of tongue, 460; with unilateral or bilateral excision of, 309.
Thyroiditis, acute non-virulent, 1046.
Tineas in human beings, 444.
Tinnitus aurium, atropine in, 105.
Tissue, a celloidin and paraffin method for embedding and hardening, 617; animal, a strange property of living, 626; connective, life of, outside of organism, 597; life of outside the organism, from the embryological standpoint, 956; life of, outside the organism from a pathological standpoint, 957; life of outside the organism, from the physiological standpoint, 956; transplantation of, 359.
Tonsil, sarcoma of, successful treatment of, 1092.
Tobacco, and snuff, use of, by school children, 1173; habitual smoking of, general effects of, 954.
Tongue, and mouth, cancer of, 461; cancer of, and its relation to syphilis, 768; malignant disease of, 500.
Tonsils, enlarged, lymphatic gland extract in the treatment of, 1137; enlarged, non-operative treatment of, 1137; septic, decreasing the risk of tonsillectomy in, 575.
Tonsillectomy, decreasing the risk of, in septic tonsil, 575; the results of, 654, 687.
Tonsillitis, nephritis following, 113.
Tonsillotomy and tonsillectomy, remote results of, 447.
Tonus, in the digestive canal, rôle of, 728.
Torticollis, following mumps and associated with cervical ribs, 664.
Tousey, S., case of exophthalmic goiter, cured by *x*-ray, 849.
Toxemia, alimentary, 631, 902, 998; alimentary, and the thyroid, 1045; cutaneous indications of, 908; alimentary, debate on, 671; alimentary, in its relation to the teeth and mouth, 898; of pregnancy, a new method of treating, 66.
Trachoma, a national problem, 21; affection resembling, caused by blastomycetes, 80; treatment of, 446.
Transfusion, of blood, 313, 304; for persistent hemorrhage following sepsis, 1053; in treatment of ruptured tubal pregnancy, 444; simplified, 859.
Treatment, unskillful, limitation of action for, 276.
Tremors, some anomalous, 638.
Trichinosis, 857; a case of, with autopsy, 1169.
Tropics, medicine of, 670.
Truss, the worsted, 398.
Trypanosomes and meteorological conditions, 32.
Tubercle bacillus, bovine, in children, 1041; branched forms of, 674; human and bovine, in bone tuberculosis in children, 278; in the blood, 542, 817; in the blood in

surgical tuberculosis, 834; living and dead, relative value of, in treatment of tuberculosis, 507; mutation forms of, 1041; portals of entry of, 355; researches in, 827; virulent, appearance of, in the blood after the diagnostic tuberculin reaction, 493; route of entry of, in different animals, 444.

Tuberculides, 935.

Tuberculin, 759; as a specific cure, 952; diagnostic value of, 1179; for out-patients, 994; in tuberculosis, 355; reactions in early cases of, 1148; tests, present status of, 1079; treatment, 75, 539, 870; treatment of tuberculous bone abscess and sinuses, 858; uses of, 808.

Tuberculosis, and alcoholism, 113; and erythema nodosum, 1180; and life insurance, 1094; and menstrual disturbances, 263; and orthostatic albuminuria, 632; and pregnancy, 985; and thyrosis, 402; animal and human, 444; blood finds in, 309; blood pressures in, at high altitudes, 1149; bone, and trauma, 1178; bone, human and bovine bacilli in, 275; bone, serum in the treatment of, 828; bovine and human, 1041; bovine, hygienic significance of, 828; care of employees affected with, 1089; compulsory notification of, 718; danger of contagion from, in hospitals, 719; dispensaries, 809; dispensary and home treatment of, 714; dispensary treatment of, 169; experimental, and copper, 630; experimental bone and joint, 827; foci in, treated with *x*-rays, 542; Friedmann treatment of, see Friedmann, F. F.; genital, in the female, management of, 728; genitourinary, paths of infection in, 446; hospital control of, 76; in childhood, 345, 633; in early life, 470; in France, 177; in infancy and childhood, 768; in relation to pregancy, labor, and puerperium, 182; lecithin and cholin as remedies in, 861; living and dead tubercle bacilli in the treatment of, 507; notification of, 349; meningeal, glycosuria in, 172; of bone, treatment of with tuberculin, 858; of cervical glands, conservative treatment of, 12; of large arteries, 950; of larynx, 997; of larynx, cauterization in, 213; of larynx, treatment of painful dysphagia of, 322; of liver with jaundice, 950; of upper air passages, formalin in treatment of, 92; official report on, in England, 627; pulmonary, see pulmonary tuberculosis; prevention and relief of, by examination of the exposed, 869; problems of, 173; reduction of mortality from, 81; relation of bovine and human, 1193; secondary, 80; specific treatment of, 123; surgical, 618; surgical, tubercle bacilli in the blood in, 834; tuberculin reactions in early cases of, 1148; tuberculin treatment of, 172, 355, 539, 630, 870; types of organism in bone and joint, 814; vaccination against, 1059; warfare against, in the United States, newer problems of, 86.

Tumors, and inefficient immunity, 354; animal, studies in, 355; atheromatous, familial incidence of, 449; growth of, and lecithin and cholesterin, 827; malignant, see cancer, 490; non-operative treatment of, 74; removal of, and diabetes, 490; superficial, radium treatment of, 1090.

Tuning-fork tests, 302.

Typhloalbuminuria, 867.

Typhoid bacillus, anaphylotoxins and endotoxins of, 346.

Typhoid fever, apparent increase of, in the Philippines, 397; apyrexial, 400; carriers, surgical treatment of, 860; duration of infectivity of, 34; high calory diet in, 523; inoculation against, 10, 37, 90, 582, 1097; late suppuration osteitis following, 354; live attenuated vaccines in, 540; milk-free treatment of, 305; skin reaction in, 1175; vaccination against in France, 304; at the Massachusetts General Hospital, 258.

Typhus fever in the United States, 1178.

U

Ulcers, leg, chronic, treatment of, 352; gastric, see stomach; of stomach, see stomach; of the bladder, 656.

Umbilicus concretions of, 1001.

Unreality, the feeling of, 352.

Urachus, fistula from, 999.

Uranalysis, simple and exact, 125.

Ureter, and kidney, calculi of, 169; calculi of diagnosis and treatment of, 320; doubles, 77; examination of, in various diseases of the kidney, and ureter with the aid of dyestuffs administered to the patient, 213; lithiasis of, 469; obstruction of, 582.

Uremia, striking phenomena of, 1138.

Ureterocele, occlusion of ureter, and hydronephrosis, 589.

Ureterovesical valve, 121.

Urethra, caruncle of, 859; impermeable stricture of, 259; folliculitis of, 204; lithiasis of, 271, 538; remote effects of lesions in the deep, 1147.

Urethritis and the *Micrococcus catarrhalis*, 539.

Urethrorrhea *ex libidine*, prostatic elements in, 310.

Urethrotomy, comparison of internal and external, 19.

Uric acid, how prevented by phenol, 86; studies on, in the blood and urine, 1148.

Urine, analysis of, in insurance examinations, 725; pus in, as an intermittent phenomena, 722.

Uterus, cancer of, 892; cancer of, and publicity, 674; cancer of, bacteria in relation to, 355; cancer of, best operation for, 229; cancer of, radical abdominal operation for, 363; cancer of, reduction of mortality from, 774; cancer of the cervix of, examination of the bladder in, 1087; cervical myoma of, and ovarian cyst with twisted pedicle, 642; diseases of, in relation to the thyroid, 1047; fibroids of, 906; fibroids of, bacteria in relation to, 355; fibroids of, hyaline and cystic, with cystic ovaries, 181; fibroids of, malignant degeneration associated with, 226; fibroids of, multiple, with adenocarcinoma of the fundus uteri, 225; fibroids of, sarcomatous degeneration of, 226; growths of, associated with goiter and exophthalmic goiter, 822; hemorrhage from modern styptics in treatment of, 1181; intramural abscess of, 489; myomatous, complicated with suppurating ovarian cyst, 642; operation for marked descensus of by the Dührssen-Bandler method, 639; procidentia of, vaginal shortening of the uterosacral ligaments in, 642; submucous myoma of, with extreme rigidity of pelvic floor, 642; unicornis, pregnancy in, 362; ventofixation of, 763.

V

Vaccination, against meningitis, 859; against tuberculosis, 1059; typhoid, 58, 90; antityphoid, 10; of the tongue, 79; with living microorganisms, 908.

Vaccine, in pertussis, 344; treatment, 492; therapy, current developments and problems of, 1097; treatment of erysipelas in infants, 573.

Vaccines, and fevers, 400; in gonorrheal ophthalmia, 428; live attenuated in typhoid and paratyphoid fevers, 540; the uses of, 1043.

Vagina, surgery of, value of inverted T-incision in, 1164.

Valve, ileocecal, incompetency of, 1105.

Valvulitis, uricemic, 241.

Vandegrift, G. W., the etiology of iritis, 341.

Varicella, and herpes zoster, 33; in adults, 1093.

Variola, and poliomyelitis, 766; and vaccinia, 812; microbiology of, 252.

Varix, dissecting, 536.

Vasostomy in chronic seminal vesiculitis, 31.

Vein, portal, ligation of, 590.

Venereal diseases, acute, hospital accommodations for, 453; attitude of Department of Health in relation to, 452; in the negro, 983; notification of, 485; prophylaxis of, 1132; reporting of, protest against, 684; resolution regarding treatment of, 455.

Ventricle, third, colloid tumor of, 214.

Veronal, death from, 764.

Vertebrae, and ribs, congenital fusion of first, second and third dorsal, 919; cervical, fracture-dislocation of, causing injury of spinal nerve roots, 680.

Vertigo, 906; aural, 31; labyrinthine, caused by local autogenous temperature variations, 1125.

Vesiculitis, chronic seminal, vasostomy in, 31; seminal, chronic, 673.

Vienna, as center for postgraduate medical study, 721.

Vincent's angina, 424; salvarsan in, 644.

Vinton, M. M., state care for mental defectives, 528.

Viscera, a case of complete transposition of the, 1170.

Vision, defects in the central field of, 29; unconscious impairment of, 629.

Voice restored by paraffin injection, 1173.

Vomiting, postanesthetic treatment of, 92.

Von Noorden, C., radium and thorium-*x* therapy, 95.

Von Ruck, K., the relative value of living and dead tubercle bacilli and of their endotoxins in solution in active immunization against tuberculosis, 507.

Vulvovaginitis in children, 1190.

W

Warbrick, J. C., indicanuria and the phosphates, 297.

Wassermann reaction, 949; and its value in the detection of syphilis, 356; contraindications to, 445; in the insane, 720; in various conditions in children, 823.

Water, distilled, harmfulness of, 79; in relation to diuresis, 827; in the treatment of syphilis, 769; purification of, by storage, 390.

Weber test, prognostic value of, 103.

Wile, I. S., hygiene for the normal child, 199; the economic importance of speech defects, 1161.

Williams, B. G. R., observations on some clinical features of painful oxaluria, 1076.

Williams, E. H., the menace of the "recovered" insane, 565.

Williams, Linsly R., the sewerage problem in New York City, 409.

Williams, T. A., occupation neuroses, their true nature and treatment, 464.

Witness, examination as to professional fees of, 574; expert, competency as, 276.

Woman, the rôle of, 532.

Workingmen, insurance of, 543.

Wounds, granulating, treated by means of ointments, 858; gunshot, of the abdomen, 181; healing, and general asthenia of connective tissue, 953; treated with sugar, 542.

Wright, B. L., the treatment of diseases of vegetable parasitic origin by deep injections of mercury, 323.

X

*X*-ray, abuse of, in dermatology, 949; action of, upon eosinophiles, 204; and radium and their influence on deep-seated cancer, 493; apparatus, portable, 270; examination of the appendix, 815; examinations versus clinical methods in the diagnosis of gastric disease, 1066; in gynecology, 32; in ovariogenous affections, 1001; injuries not an accident, 587; liability of master for injuries by, 712; massive dose, method of employing, in treating skin diseases, 503; study of intestines of infants, 1149; study of the skull, lateral, 1178; treatment of tuberculous foci, 542; use of, in diagnosis of obscure abdominal conditions in infancy, 1149; use of, in pyloric obstruction, 1149.

Y

Yaws, mistaken for epilepsy, 765.

Z

Ziegel, H. F. L., a case of Graves' disease with scleroderma and a positive Wassermann reaction, treated with salvarsan, 1124.
